The COE would modify the Area of Potential Effects (APE) to the proposed undertaking's activities that fall under Section 404 of the Clean Water Act for the placement of fill in jurisdictional waters of the United States and Section 408 of the Rivers and Harbors Act of 1899 for alteration of federal project levees. The COE initiated consultation for the project on April 4, 2011. In a letter, dated April 6, 2011, I concurred with the COE determination of No Adverse Effect for the proposed undertaking. You now inform me that the COE is requesting my concurrence with the expanded APE and their finding of no adverse effects to historic properties.

The modified APE includes an augmentation of the project in three areas (identified in the cultural resources report as project areas IIIa, VIIa.4-Viib, and VIIe) totaling approximately 10.7-acres. In project areas IIIa, VIa.4 through VIb, and VIIe, approximately 25 to 35 meters have been added to the width of the previously defined APE. Project area VIIb has expanded by approximately 0.4 acres and now includes an existing raised dirt road that extends from the west end of Madruga Road for approximately 590 meters to the levee.

The cultural resources identification efforts conducted in association with the previously issued COE permit included a records search, survey, and Native American coordination performed by AECOM (Consultant) in 2010 and 2011. The previously conducted identification efforts identified three potential historic resources within the project's APE, one of which, CA-SJO-250H, the old southern Pacific rail line and vertical-lift drawbridge, had previously been determined eligible for listing on the National Register of Historic Places (NRHP). The COE determined that the other two resources, including P-39-004602 (the Silveria Ranch) and the RD 17 levee itself, were ineligible for listing on the NRHP. In a letter dated April 6, 2011, I concurred with the COE's finding of "No Adverse Effect" for the proposed undertaking.

The Archaeological Survey Report prepared by the consultant in September 2014 indicates that the areas within the expanded APE were subject to a records search, Native American coordination, and field investigation conducted by AECOM between March and June, 2014. The records search, conducted by the consultant on June 3, 2014, identified one previously recorded cultural resource, CA-SJO-3 (a large prehistoric-era habitation site), within the expanded APE. Previous investigations conducted for Caltrans found that deeply buried intact deposits still exist at CA-SJO-3 and recommended the site eligible for listing on the NRHP. In 2003, my office concurred with Caltrans' finding that CA-SJO-3 was eligible for NRHP listing.

The pedestrian survey, conducted on March 4, March 11, and April 23, 2014, did not result in the identification of additional cultural resources within the expanded APE. The Native American Heritage Commission (NAHC) was contacted by the consultant on March 20, 2014 and had not responded by September 2014. Previous consultation with the NAHC associated with the initial project did not result in the identification any known Native American sacred lands or areas of cultural importance within the vicinity of the project area. Native American coordination initiated by the consultant on May 28, 2014 has not resulted in the identification of potential historic properties within the expanded APE.

In assessing potential adverse effects to site CA-SJO-3, the COE has determined that, due to the approximately 3 meters of fill over the site and because the proposed activities within the boundaries of CA-SJO-3 are limited to the use of an existing raised roadway, the project will continue to have no adverse effect to historic properties.

The COE is requesting my review and comment on the adequacy of their historic property identification efforts, determination of National Register of Historic Places (NRHP) eligibility, and finding of effect associated with the proposed undertaking. After reviewing your submission I have the following comments:

- Pursuant to 36 CFR 800.4(a)(1), I have no objections to the revised APE as defined.

- Pursuant to 36 CFR 800.4(b), I find that the COE has made a reasonable and good faith effort to identify historic properties within the area of potential effects.

- Pursuant to 36 CFR 800.3(e) and (f), the COE is responsible for carrying out consultation with Indian tribes, the public, and other interested parties. A federal agency cannot delegate its government-to-government consultation with Indian tribes to applicants or other non-federal entities, including state and local governments, without prior consent from the tribes. It is important to remember that Indian tribes are under no obligation to consult directly with an applicant. Absent a formal agreement or approved protocol previously negotiated between the federal agency and the Indian tribe, an agency must initiate and conduct the consultation process with the Indian tribe.

- Pursuant to 36 CFR 800.4(c)(2), I concur that the prehistoric site CA-SJO-3 is eligible for listing on the NRHP.
- Pursuant to 36 CFR 800.5(c)(1), I concur with your determination of no adverse effects to historic properties for this undertaking.

Thank you for seeking my comments and considering historic properties as part of your project planning. Be advised that under certain circumstances, such as unanticipated discovery or a change in project description, the COE may have additional future responsibilities for this undertaking under 36 CFR Part 800. If you have any questions, please contact Patrick Riordan of my staff at (916) 445-7017 or Patrick.Riordan@parks.ca.gov.

Sincerely,

Carol Roland-Nawi, Ph.D.

Carol Roland-Nawi, PhD
State Historic Preservation Officer

Fugitive PM10 Emissions	448.77	lb/project

Quantities of Fill Required for the Minimum Footprint Alternative (Alternative 1)

Material Type	Cubic Yards (CY)	Average Round-Trip (Haul Distance)	Total 1-Way Trips	Total Roundtrip Miles
Levee Fill Material	47,122	8	2618	20943
Seepage berm fill	342,963	8	19054	152428
Drain rock	83,901	8	6454	51631
Filter material 3/8 inch (Sand)	8,029	8	446	3568
Aggregate base	14,066	8	781	6252
Asphalt concrete	44,571	5	3429	17143
Steel Sheet Piles (Element VIIe only)	182	8	10	81
Total	**540,834**	-	-	-
Dual Bottom Dump Truck Capacity (CY)[4]	18	-	-	-
Avg. Haul Truck Capacity (CY)[5]	13	-	-	-
Project Duration (days)[6]	160	-	-	-
		Total =	**32,791**	**252,046**

Notes:
1. Emission factor represents running exhaust, tire wear, and break wear (grams/mile)
2. Emission factor represents start emission rate @ 480 minutes (grams/trip)
3. Accounts for 2 starts per trip.
4. Dual bottom-dump trucks would haul fill, sand, and aggregate base.
5. Haul trucks would haul drain rock and aggregate base.
6. Duration based on 123-day construction season which assumes 80 work days for two years; therefore, duration represents total project activity.

Emission Factor	**0.00178049**	lbs/VMT
Fugitive PM10 Emissions	437.24	lb/project

Quantities of Fill Required for Preferred Alternative				
Material Type	Cubic Yards (CY)	Average Round-Trip (Haul Distance)	Total 1-Way Trips	Total Roundtrip Miles
Seepage berm fill	7,000	8	389	3111
Levee fill	131,000	8	24778	198224
Drain rock	5,500	8	423	3385
Filter material 3/8 inch (sand)	1,500	8	83	667
Aggregate base	8,500	8	1577	12616
Asphalt concrete	0	8	3446	27568
Total	**153,500**	-	-	-
Dual Bottom Dump Truck Capacity (CY)[3]	18	-	-	-
Avg. Haul Truck Capacity (CY)[4]	13	-	-	-
Project Duration (days)[5]	160	-	-	-
		Total =	**30,696**	**245,570**

Notes:
1. Emission factor represents running exhaust, tire wear, and break wear (grams/mile)
2. Emission factor represents start emission rate @ 480 minutes (grams/trip)
3. Dual bottom-dump trucks would haul fill, sand, and aggregate base.
4. Haul trucks would haul drain rock and aggregate base.
5. Duration based on 123-day construction season which assumes 80 work days for two years; therefore, duration represents total project activity.

Aggregate Storage Piles - Emissions Factor Calculation

Emissions result from several distinct processes within the stockpiling cycle: 1. loading in of materials through batch or drop operations,
2. equipment traffic in storage areas, 3. wind erosion of piles, 4. loadout of material through batch or drop operations
E(lb/ton)=(k)(0.0032)(U/5)^1.3/(M/2)^1.4

Where:	**PM10**	Unit	Source
k= Particle Size Multiplier:	0.35	lbs/ton	AP-42 Chapter 13.2.4-3, PM10 emissions
U=mean wind speed	6	mph	CalEEMod for San Joaquin County
M=moisture content (%)	3.400	constant	AP-42 Chapter 13.2.4-3, Table 13.2.4-1, exposed ground
	0.00068	**lbs/ton**

2. Construction Activity (grading and earthmoving)

Grading Equipment	Alternative 1			Alternative 2			Preferred Alternative		
	Equipment Hours		Dust Emissions	Equipment Hours		Dust Emissions	Equipment Hours		Dust Emissions
		Daily Hours (avg)	PM10 (lbs/day)		Daily Hours (avg)	PM10 (lbs/day)		Daily Hours (avg)	PM10 (lbs/day)
Bulldozers + Graders	(across all segments)	6.509	4.90	(across all segments)	6.63	4.99	(across all segments)	7.47	5.63
Total			**4.90**			**4.99**			**5.63**

Bulldozing and Grading - Emission Factor Calculation

Equation is applied to graders and dozers to estimate fugitive dust from grading activity
Emissions factors for P10 from bulldozing are scaled from those of PM15

E(lbs/hr)=C(PM15)*s^1.5/M^1.5
Where
E(PM10)=E(PM15)*F(PM10)

			PM15	
Where:			Unit	Source

Appendix I. Environmental Permits Issued to Date for the Phase 3 Repair Project

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS, SACRAMENTO DISTRICT
1325 J STREET
SACRAMENTO CA 95814-2922

April 6, 2017

Regulatory Division (SPK-2009-01466)

Reclamation District (RD) 17
Attn: Mr. Christopher Neudeck
Kjeldsen-Sinnock & Associates, Inc.
711 North Pershing Avenue
Stockton, California 95203

Dear Mr. Neudeck:

We are responding to your March 21, 2017, request for a Department of the Army permit for the RD17 100-Year Levee Seepage Project. This approximately 4.54-acre project involves activities, including discharges of dredged or fill material, in waters of the United States (WOUS) to construct seepage berms to prevent flooding. The project consist of three separate sites totaling approximately 4.54-acre along the San Joaquin River, Latitude 37.8017°, Longitude -121.3136°, Latitude 37.8653°, Longitude -121.3242°, Latitude 37.8186°, Longitude -121.3142°, San Joaquin County, California.

Based on the information you provided, the proposed activity, resulting in the permanent loss of approximately 0.55 acre of wetlands and 0.15 acre of drainage ditches is authorized by Regional General Permit (RGP) number 8. **Your work must comply with the general terms and conditions listed on the enclosed RGP information sheets and the following special conditions (enclosure 1)**:

Special Conditions

1. You shall notify the Corps of the start and completion dates for each phase of the authorized work within 1 calendar day prior to initiation of construction activities within WOUS and 30 calendar days following completion of construction activities.

2. To mitigate for the loss of 0.70 acre of WOUS (0.55 acre of wetlands and 0.15 acre of drainage ditches), you shall purchase 0.55 credits of Floodplain Mosaic Wetlands and 0.15 credits of Floodplain Riparian habitat at Cosumnes Floodplain Mitigation Bank. Evidence of this purchase shall be provided to the Corps within 30 days of authorized discharge of fill or dredge material in WOUS.

3. The enclosure document titled *Figure 3, 4 and 5, "Effects to Waters of the United States – Elements Ia and Ib, 1e, IIIa, IIIb, and Iva"*, dated May 2014, is incorporated as the permit boundary this authorization (enclosure 2).

4. Additionally, if the proposed activities intends to alter the Lower San Joaquin River and Tributaries Project and will require an authorization under Section 14 of the Rivers and Harbors Act of 1899, as amended, and codified in 33 USC 408 (Section 408) if it is to remain in place beyond the duration of the imminent threat to life or property.

You must sign the enclosed Compliance Certification and return it to this office within 30 days after completion of the authorized work.

This verification is valid for two years from the date of this letter or until the RGP is modified, reissued, or revoked, whichever comes first. Failure to comply with the General Conditions of this RGP, or the project-specific Special Conditions of this authorization, may result in the suspension or revocation of your authorization.

We appreciate your feedback. At your earliest convenience, please tell us how we are doing by completing the customer survey on our website under *Customer Service Survey.*

Please refer to identification number SPK-2009-01466 in any correspondence concerning this project. If you have any questions, please contact Mr. Peck Ha at the above address, by email at *Peck.Ha@usace.army.mil,* or telephone at (916) 557-6617. For more information regarding our program, please visit our website at *www.spk.usace.army.mil/Missions/Regulatory.aspx*.

COMPLIANCE CERTIFICATION

Permit File Number: SPK-2009-01466

Regional General Permit Number: 8

Permittee: Reclamation District (RD) 17
Attn: Mr. Christopher Neudeck
Kjeldsen-Sinnock & Associates, Inc.
711 North Pershing Avenue
Stockton, California 95203

County: San Joaquin

Date of Verification: April 6, 2017

Within 30 days after completion of the activity authorized by this permit, sign this certification and return it to the following address:

U.S. Army Corps of Engineers
Sacramento District
DLL-CESPK-RD-Compliance@usace.army.mil

Please note that your permitted activity is subject to a compliance inspection by a U.S. Army Corps of Engineers representative. If you fail to comply with the terms and conditions of the permit your authorization may be suspended, modified, or revoked. If you have any questions about this certification, please contact the U.S. Army Corps of Engineers.

* * * * * * * * * *

I hereby certify that the work authorized by the above-referenced permit, including all the required mitigation, was completed in accordance with the terms and conditions of the permit verification.

Signature of Permittee Date

Cosumnes Floodplain Mitigation Bank
AGREEMENT FOR SALE OF MITIGATION CREDITS
Permit Number: SPK-2009-01466

This Agreement is entered into this 13th day of April, 2017 by and between WESTERVELT ECOLOGICAL SERVICES, LLC (Bank Owner) and the RECLAMATION DISTRICT 17 (Project Applicant), jointly referred to as the "Parties," as follows:

RECITALS

A. The Bank Owner has developed the Cosumnes Floodplain Mitigation Bank (Bank) located in Sacramento County, California; and

B. The Bank was approved by the U.S. Army Corps of Engineers (USACE), U.S. Environmental Protection Agency (USEPA), National Marine Fisheries Service (NMFS) and California Department of Fish and Wildlife (CDFW) (jointly referred to as "Agencies") on **September 30, 2009**, and is currently in good standing with these agencies; and

C. The Bank has received approval from the Agencies to offer riparian wetlands and seasonal wetlands under the Clean Water Act and riparian forest, Scrub Shrub, and Shaded Riverine Aquatic (SRA) credits through the *Cosumnes Floodplain Mitigation Bank Enabling Instrument* (Bank Agreement); and

D. Project Applicant is seeking to implement an Emergency Flood Response action described on Exhibit "A" attached hereto (Project), which would unavoidably and adversely impact aquatic and riparian habitat and seeks to compensate for the loss of the aquatic and riparian habitat by purchasing Credits from the Bank; and

E. Project Applicant has been authorized by the U.S. Army Corps of Engineers, (Permit Number: SPK-2009-01466), to purchase from the Bank **0.55 Floodplain Mosaic Wetland credits and 0.15 Floodplain Riparian Habitat credits** upon confirmation by the Bank Owner of credit availability/adequate balance of credits remaining for sale; and

F. Project Applicant has been authorized by the Central Valley Regional Water Quality Control Board (Water Quality Certification Number: 5B39CR00238), to purchase from the Bank **0.07 Floodplain Riparian Habitat credits** to mitigate for future impacts related to the Reclamation District Phase 3 Levee Seepage Repair Project which involves discharge of dredged or fill material that would result in loss of an additional approximately 0.07 acres of aquatic habitat; and

G. Project Applicant desires to purchase from Bank and Bank desires to sell to Project Applicant **0.55 Floodplain Mosaic Wetland credits and 0.22 Floodplain Riparian Habitat credits**;

NOW, THEREFORE, THE PARTIES AGREE AS FOLLOWS:

1. Bank hereby sells to Project Applicant and Project Applicant hereby purchases from Bank **0.55 Floodplain Mosaic Wetland credits and 0.22 Floodplain Riparian Habitat credits** for the purchase price of **$98,450.00**. The Bank will then deliver to Project Applicant an executed Bill of Sale in the manner and form as attached hereto and marked Exhibit "B". The purchase price for said credits shall be paid by cashier's check or, at the option of Bank, wire transfer of funds according to written instructions by Bank to Project Applicant.

2. The sale and transfer herein is not intended as a sale or transfer to Project Applicant of a security, license, lease, easement, or possessory or non-possessory interest in real property, nor the granting of any interest of the foregoing.

3. Project Applicant shall have no obligation whatsoever by reason of the purchase of the Credits, to support, pay for, monitor, report on, sustain, continue in perpetuity, or otherwise be obligated or liable for the success or continued expense or maintenance in perpetuity of the credits sold, or the Bank. Pursuant to the Bank Agreement and any amendments thereto, Bank shall monitor and make reports to the appropriate agency or agencies on the status of any Credits sold to Project Applicant. Bank shall be fully and completely responsible for satisfying any and all conditions placed on the Bank or the Credits by all state or federal jurisdictional agencies.

4. The Credits sold and transferred to Project Applicant shall be non-transferable and non-assignable, and shall not be used as compensatory mitigation for any other Project or purpose, except as set forth herein.

5. Project Applicant hereby commits to purchase the Credits and in association therewith shall tender payment for the Credits no later than 30 days from the date of this Agreement.

6. Upon purchase of the credits specified in paragraph E above, the Bank shall submit to the parties listed in the Notices section of the Bank Agreement / Bank Enabling Instrument, copies of the: a) Agreement for Sale of Credits; b) Bill of Sale; c) Payment Receipt; and d) an updated ledger. The updated inventory / ledger must detail: i) Project Applicant; ii) Project Name; iii) Status (sale complete/sale not complete); iv) Credit Sale Date; v) Service File Number; vi) U.S. Army Corps of Engineers File Number (if applicable); vii) Total Number of Credits Authorized to Sell; viii) Total Number of Credits Sold to Date (inclusive); and ix) Balance of all Credits Available. The inventory / ledger should include all sales data from bank opening/establishment to the present.

IN WITNESS WHEREOF, the parties have executed this Agreement the day and year first above written.

Exhibit "A"

DESCRIPTION OF PROJECT
TO BE
MITIGATED

The Reclamation District 17 Emergency Flood Response action is an approximate 4.54-acre project involving activities previously identified as part of the Reclamation District 17 Phase 3 Levee Seepage Repair Project, and include discharges of dredged or fill material, in waters of the United States (WOUS) to construct seepage berms to prevent flooding. The proposed activity will result in the permanent loss of approximately 0.55 acre of wetland and 0.15 acre of drainage ditches and is authorized by Regional General Permit number 8, Permit File Number SPK-2009-01466. The Reclamation District 17 Phase 3 Levee Seepage Repair Project also would involve discharge of dredged or fill material that would result in loss of an additional approximately 0.07 acres of WOUS in the future to construct seepage berms to prevent flooding.

Exhibit "B"

BILL OF SALE

In consideration of **$98,450.00**, receipt of which is hereby acknowledged, *Westervelt Ecological Services, LLC (Bank Owner)* does hereby bargain, sell and transfer to the *Reclamation District 17* **0.55 Floodplain Mosaic Wetland credits and 0.22 Floodplain Riparian Habitat credits** in the *Cosumnes Floodplain Mitigation Bank* in Sacramento County, California, developed, and approved by the U.S. Army Corps of Engineers, U.S. Environmental Protection Agency, California Department of Fish and Wildlife, and National Marine Fisheries Service.

Westervelt Ecological Services, LLC represents and warrants that it has good title to the credits, has good right to sell the same, and that they are free and clear of all claims, liens, or encumbrances.

Westervelt Ecological Services, LLC covenants and agrees with the buyer to warrant and defend the sale of the credits hereinbefore described against all and every person and persons whomsoever lawfully claiming or to claim the same.

DATED: 4/24/2017

PARTICIPANT INFORMATION

Name: Reclamation District 17

Address: P.O. Box 1461, Stockton, CA 95201

Telephone: 209-465-5883

Contact: Dante Nomellini Sr.

PROJECT INFORMATION

Project Name: Emergency Flood Response Action

Corps Permit Number: SPK-2009-01466

Water Quality Certification Number: 5B39CR00238

Species/Habitat Affected: Aquatic and Riparian habitat

Credits to be Purchased: 0.22 Floodplain Riparian Habitat credits, 0.55 Floodplain Mosaic Wetland credits

Payment Amount: $98,450.00

Project Location: San Joaquin County River

County/Address: San Joaquin County

PAYMENT INFORMATION

Payee: Westervelt Ecological Services, LLC

Payer: Reclamation District 17

Amount: Ninety-Eight Thousand Four Hundred and Fifty Dollars

Method of payment: Cash Check No. 801332 Money Order No.

CLEAN WATER ACT §401 TECHNICALLY CONDITIONED WATER QUALITY CERTIFICATION FOR DISCHARGE OF DREDGED AND/OR FILL MATERIALS FOR THE RECLAMATION DISTRICT 17 PHASE 3 100-YEAR LEVEE SEEPAGE AREA PROJECT (WDID#5B39CR00238), MANTECA, SAN JOAQUIN COUNTY

ACTION:

1. ☐ Order for Standard Certification

2. ■ Order for Technically-conditioned Certification

3. ☐ Order for Denial of Certification

WATER QUALITY CERTIFICATION STANDARD CONDITIONS:

1. This certification action is subject to modification or revocation upon administrative or judicial review, including review and amendment pursuant to §13330 of the California Water Code and §3867 of Title 23 of the California Code of Regulations (23 CCR).

2. This certification action is not intended and shall not be construed to apply to any discharge from any activity involving a hydroelectric facility requiring a Federal Energy Regulatory Commission (FERC) license or an amendment to a FERC license unless the pertinent certification application was filed pursuant to 23 CCR subsection 3855(b) and the application specifically identified that a FERC license or amendment to a FERC license for a hydroelectric facility was being sought.

3. The validity of any non-denial certification action shall be conditioned upon total payment of the full fee required under 23 CCR §3833, unless otherwise stated in writing by the certifying agency.

4. Certification is valid for the duration of the described project. Reclamation District 17 shall notify the Central Valley Water Board in writing within 7 days of project completion.

ADDITIONAL TECHNICALLY CONDITIONED CERTIFICATION CONDITIONS:

In addition to the four standard conditions, Reclamation District 17 shall satisfy the following:

1. Reclamation District 17 shall notify the Central Valley Water Board in writing 7 days in advance of the start of any in-water activities.

2. Except for activities permitted by the U.S. Army Corps under §404 of the Clean Water Act, soil, silt, or other organic materials shall not be placed where such materials could pass into surface water or surface water drainage courses.

3. All areas disturbed by project activities shall be protected from washout or erosion.

4. Reclamation District 17 shall maintain a copy of this Certification and supporting documentation (Project Information Sheet) at the Project site during construction for review by site personnel and agencies. All personnel (employees, contractors, and subcontractors) performing work on the proposed project shall be adequately informed and trained regarding the conditions of this Certification.

5. An effective combination of erosion and sediment control Best Management Practices (BMPs) must be implemented and adequately working during all phases of construction.

6. All temporarily affected areas will be restored to pre-construction contours and conditions upon completion of construction activities.

7. Reclamation District 17 shall perform surface water sampling: 1) When performing any in-water work; 2) In the event that project activities result in any materials reaching surface waters or; 3) When any activities result in the creation of a visible plume in surface waters. The following monitoring shall be conducted immediately upstream out of the influence of the project and 300 feet downstream of the active work area. Sampling results shall be submitted to this office within two weeks of initiation of sampling and every two weeks thereafter. The sampling frequency may be modified for certain projects with written permission from the Central Valley Water Board.

Parameter	Unit	Type of Sample	Frequency of Sample
Turbidity	NTU	Grab	Every 4 hours during in water work
Settleable Material	ml/l	Grab	Same as above.
Visible construction related pollutants	Observations	Visible Inspections	Continuous throughout the construction period

8. Activities shall not cause turbidity increases in surface water to exceed:

   (a) where natural turbidity is less than 1 Nephelometric Turbidity Units (NTUs), controllable factors shall not cause downstream turbidity to exceed 2 NTU;
   (b) where natural turbidity is between 1 and 5 NTUs, increases shall not exceed 1 NTU;
   (c) where natural turbidity is between 5 and 50 NTUs, increases shall not exceed 20 percent;
   (d) where natural turbidity is between 50 and 100 NTUs, increases shall not exceed 10 NTUs;
   (e) where natural turbidity is greater than 100 NTUs, increases shall not exceed 10 percent.

   Except that these limits will be eased during in-water working periods to allow a turbidity increase of 15 NTU over background turbidity as measured in surface waters 300 feet downstream from the working area. In determining compliance with the above limits, appropriate averaging periods may be applied provided that beneficial uses will be fully protected. Averaging periods may only be assessed by prior permission of the Central Valley Water Board.

9. Activities shall not cause settleable matter to exceed 0.1 ml/l in surface waters as measured in surface waters 300 feet downstream from the project.

10. The discharge of petroleum products or other excavated materials to surface water is prohibited. Activities shall not cause visible oil, grease, or foam in the work area or downstream. Reclamation District 17 shall notify the Central Valley Water Board immediately of any spill of petroleum products or other organic or earthen materials.

11. Reclamation District 17 shall notify the Central Valley Water Board immediately if the above criteria for turbidity, settleable matter, oil/grease, or foam are exceeded.

12. Reclamation District 17 shall comply with all Department of Fish and Wildlife 1600 requirements for the project.

13. Reclamation District 17 must obtain coverage under the NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities issued by the State Water Resources Control Board for any project disturbing an area of 1 acre or greater.

14. The Conditions in this water quality certification are based on the information in the attached "Project Information." If the information in the attached Project Information is modified or the project changes, this water quality certification is no longer valid until amended by the Central Valley Water Board.

15. In the event of any violation or threatened violation of the conditions of this Order, the violation or threatened violation shall be subject to any remedies, penalties, process, or sanctions as provided for under State law and section 401 (d) of the federal Clean Water Act. The applicability of any State law authorizing remedies, penalties, process, or sanctions for the violation or threatened violation constitutes a limitation necessary to ensure

compliance into this Order.

a. If Reclamation District 17 or a duly authorized representative of the project fails or refuses to furnish technical or monitoring reports, as required under this Order, or falsifies any information provided in the monitoring reports, the applicant is subject to civil monetary liabilities, for each day of violation, or criminal liability.

b. In response to a suspected violation of any condition of this Order, the Central Valley Water Board may require Reclamation District 17 to furnish, under penalty of perjury, any technical or monitoring reports the Central Valley Water Board deems appropriate, provided that the burden, including cost of the reports, shall be in reasonable relationship to the need for the reports and the benefits to be obtained from the reports.

c. Reclamation District 17 shall allow the staff(s) of the Central Valley Water Board, or an authorized representative(s), upon the presentation of credentials and other documents, as may be required by law, to enter the project premises for inspection, including taking photographs and securing copies of project-related records, for the purpose of assuring compliance with this certification and determining the ecological success of the project.

ADDITIONAL STORM WATER QUALITY CONDITIONS:

Reclamation District 17 shall also satisfy the following additional storm water quality conditions:

1. During the construction phase, Reclamation District 17 must employ strategies to minimize erosion and the introduction of pollutants into storm water runoff. These strategies must include the following:

   (a) the Storm Water Pollution Prevention Plan (SWPPP) must be prepared during the project planning and design phases and before construction;
   (b) an effective combination of erosion and sediment control Best Management Practices (BMPs) must be implemented and adequately working prior to the rainy season and during all phases of construction.

2. Reclamation District 17 must minimize the short and long-term impacts on receiving water quality from the Reclamation District 17 Phase 3 100-Year Levee Seepage Area Project by implementing the following post-construction storm water management practices:

   (a) minimize the amount of impervious surface;
   (b) reduce peak runoff flows;
   (c) provide treatment BMPs to reduce pollutants in runoff;
   (d) ensure existing waters of the State (e.g., wetlands, vernal pools, or creeks) are not used as pollutant source controls and/or treatment controls;
   (e) preserve and, where possible, create or restore areas that provide important water quality benefits, such as riparian corridors, wetlands, and buffer zones;
   (f) limit disturbances of natural water bodies and natural drainage systems caused by development (including development of roads, highways, and bridges);
   (g) use existing drainage master plans or studies to estimate increases in pollutant loads and flows resulting from projected future development and require

incorporation of structural and non-structural BMPs to mitigate the projected pollutant load increases in surface water runoff;

(h) identify and avoid development in areas that are particularly susceptible to erosion and sediment loss, or establish development guidance that protects areas from erosion/ sediment loss;

(i) control post-development peak storm water run-off discharge rates and velocities to prevent or reduce downstream erosion, and to protect stream habitat.

3. Reclamation District 17 must ensure that all development within the project provides verification of maintenance provisions for post-construction structural and treatment control BMPs. Verification shall include one or more of the following, as applicable:

(a) the developer's signed statement accepting responsibility for maintenance until the maintenance responsibility is legally transferred to another party; or

(b) written conditions in the sales or lease agreement that require the recipient to assume responsibility for maintenance; or

(c) written text in project conditions, covenants and restrictions for residential properties assigning maintenance responsibilities to a home owner's association, or other appropriate group, for maintenance of structural and treatment control BMPs; or

(d) any other legally enforceable agreement that assigns responsibility for storm water BMP maintenance.

4. Staff of the Central Valley Water Board has prepared total maximum daily load (TMDL) allocations that, once approved, would limit methylmercury in storm water discharges to the Sacramento-San Joaquin Delta. The Central Valley Water Board has scheduled these proposed allocations to be considered for adoption. When the Central Valley Water Board adopts the TMDL and once approved by the Environmental Protection Agency, the discharge of methylmercury may be limited from the proposed project. The purpose of this condition is to provide notice to Reclamation District 17 that methylmercury discharge limitations and monitoring requirements may apply to this project in the future and also to provide notice of the Central Valley Water Board's TMDL process and that elements of the planned construction may be subject to a TMDL allocation.

REGIONAL WATER QUALITY CONTROL BOARD CONTACT PERSON:

George D. Day, P.E.,Redding Branch Office, 364 Knollcrest Drive, Suite 205, Redding, California 96002, (530) 224-4845

WATER QUALITY CERTIFICATION:

I hereby issue an order certifying that any discharge from Reclamation District 17, Reclamation District 17 Phase 3 100-Year Levee Seepage Area Project (WDID# 5B39CR00238) will comply with the applicable provisions of §301 ("Effluent Limitations"), §302 ("Water Quality Related Effluent Limitations"), §303 ("Water Quality Standards and Implementation Plans"), §306 ("National Standards of Performance"), and §307 ("Toxic and Pretreatment Effluent Standards") of the Clean Water Act. This discharge is also regulated under State Water Resources Control Board Water Quality Order No. 2003-0017 DWQ "Statewide General Waste Discharge

Requirements For Dredged Or Fill Discharges That Have Received State Water Quality Certification (General WDRs)."

Except insofar as may be modified by any preceding conditions, all certification actions are contingent on (a) the discharge being limited and all proposed mitigation being completed in strict compliance with Reclamation District 17's project description and the attached Project Information Sheet, and (b) compliance with all applicable requirements of the Water Quality Control Plan *for the Sacramento River and San Joaquin River*, Fourth Edition, revised October 2011 (Basin Plan).

Any person aggrieved by this action may petition the State Water Quality Control Board to review the action in accordance with California Water Code § 13320 and California Code of Regulations, title 23, § 2050 and following. The State Water Quality Control Board must receive the petition by 5:00 p.m., 30 days after the date of this action, except that if the thirtieth day following the date of this action falls on a Saturday, Sunday, or state holiday, the petition must be received by the State Water Quality Control Board by 5:00 p.m. on the next business day. Copies of the law and regulations applicable to filing petitions may be found on the Internet at: http://www.waterboards.ca.gov/public_notices/petitions/water_quality or will be provided upon request.

PROJECT INFORMATION

Application Date: 30 July 2014

Application Complete Date: 17 September 2014

Applicant: Reclamation District 17, Attn: Mr. Christopher H. Neudeck

Project Name: Reclamation District 17 Phase 3 100-Year Levee Seepage Area Project

Application Number: WDID No. 5B39CR00238

U.S. Army Corps File Number: SPK-2009-01466

Type of Project: Levee improvements including use of cutoff walls, seepage berms, chimney drains, and engineering techniques to provide 100-year level of flood protection.

Project Location: Township 1/2 South, Range 6 East, MDB&M.
Latitude: 37°52'48" and Longitude: -121°19'54"

County: San Joaquin County

Receiving Water(s) (hydrologic unit): Irrigation and drainage ditches, which are tributary to the San Joaquin River. San Joaquin Valley Floor Hydrologic Unit-Mantica Hydrologic Area No. 535.10

Water Body Type: Wetlands, Streambed

Designated Beneficial Uses: The Water Quality Control Plan *for the Sacramento River and San Joaquin River*, Fourth Edition, revised September 2009, has designated beneficial uses for surface and ground waters within the region. Beneficial uses that could be impacted by the project include: Municipal and Domestic Water Supply (MUN); Agricultural Supply (AGR); Industrial Supply (IND), Hydropower Generation (POW); Groundwater Recharge, Water Contact Recreation (REC-1); Non-Contact Water Recreation (REC-2); Warm Freshwater Habitat (WARM); Cold Freshwater Habitat (COLD); Spawning, Reproduction, and /or Early Development (SPWN); and Wildlife Habitat (WILD).

Project Description (purpose/goal): The Reclamation District (RD) 17 Phase 3 100-Year Levee Seepage Area Project consists of correcting levee geometry where needed to meet USACE design standards; increasing the levee's resistance to under-seepage and/or through-seepage; and providing seepage exit gradients of less than 0.5 at the water surface elevation associated with the 100-year flood event. Levee improvements under consideration include constructing seepage berms designed to address under-seepage, installing chimney drains in existing and new seepage berms designed to address through-seepage, installing shallow cutoff walls designed to address through-seepage, installing deep cutoff walls designed to address both under and through-seepage, and modification of levee slopes and crown widths where needed to achieve levee geometry requirements.

At three locations, RD 17 is also considering constructing setback levees largely because RD 17 desires to obtain funding for the project from DWR's Proposition 1E Early Implementation Project (EIP) program. Proposition 1E—the Disaster Preparedness and Flood Protection Bond

Act of 2006—authorized $4.09 billion in general obligation bonds to rebuild and repair California's most vulnerable structures for reducing flood damage. The EIP program prioritizes projects to more rapidly receive funding from the overall Proposition 1E funding pool. To receive EIP funding the program requires that project proponents at least consider setback levees as an option for repairing/enhancing flood control systems; acknowledging that setback levees can serve the combined purposes of improving flood protection infrastructure, reducing water surface elevations through expansion of the floodway, and providing habitat restoration/enhancement opportunities.

Preliminary Water Quality Concerns: Construction activities may impact surface waters with increased turbidity and settleable matter.

Proposed Mitigation to Address Concerns: Reclamation District 17 will implement Best Management Practices (BMPs) to control sedimentation and erosion. All temporary affected areas will be restored to pre-construction contours and conditions upon completion of construction activities. Reclamation District 17 will conduct turbidity and settleable matter testing during in-water work, stopping work if Basin Plan criteria are exceeded or are observed.

Fill/Excavation Area Project implementation will permanently impact 0.55 acre of jurisdictional wetland and 0.22 acre (2,712 linear feet) of un-vegetated streambed.

Dredge Volume: Not Applicable

U.S. Army Corps of Engineers Permit Number: Individual Permit

Department of Fish and Wildlife Streambed Alteration Agreement: Reclamation District 17 applied for a Streambed Alteration Agreement in July 2014.

Possible Listed Species: Valley elderberry longhorn beetle (VELB)

Status of CEQA Compliance: Reclamation District 17 prepared a Draft Environmental Impact Statement/Environmental Impact Report and was circulated for public comment and review in September 2011. The Reclamation District 17 will adopt the EIR in November 2014 (State Clearinghouse Number 2010042073).

Compensatory Mitigation: Reclamation District 17 will purchase 0.55 acre of floodplain mosaic wetlands and 0.22 acre of floodplain riparian habitat from the Cosumnes Floodplain Mitigation Bank, for the unavoidable impacts to jurisdictional waters.

Application Fee Provided: On 30 July 2014 a certification application fee of $5,718.00 was submitted as required by 23 CCR §3833b(3)(A) and by 23 CCR §2200(e).

Stockton, CA 95203

Subject: Final Lake or Streambed Alteration Agreement
Notification No. 1600-2014-0424-R3
San Joaquin River; RD 17 Phase 3 Levee Seepage Area Project

Dear Mr. Neudeck:

Enclosed is the final Streambed Alteration Agreement (Agreement) for the RD 17 Phase 3 Levee Seepage Area Project (Project). Before the California Department of Fish and Wildlife (Department) may issue an Agreement, it must comply with the California Environmental Quality Act (CEQA). In this case, the Department, acting as a responsible agency, filed a Notice of Determination (NOD) within five working days of signing the Agreement. The NOD was based on information contained in the Mitigated Negative Declaration prepared by the lead agency.

Under CEQA, the filing of an NOD triggers a 30-day statute of limitations period during which an interested party may challenge the filing agency's approval of the Project. You may begin the Project before the statute of limitations expires if you have obtained all necessary local, state, and federal permits or other authorizations. However, if you elect to do so, it will be at your own risk.

If you have any questions regarding this matter, please contact Melissa Farinha, Senior Environmental Scientist (Supervisory) at (707) 944-5579 or Melissa.Farinha@wildlife.ca.gov.

Sincerely,

Randi Adair

STREAMBED ALTERATION AGREEMENT
NOTIFICATION NO. 1600-2014-0424-R3
San Joaquin River

RECLAMATION DISTRICT NO. 17
RD 17 PHASE 3 LEVEE SEEPAGE AREA PROJECT

This Streambed Alteration Agreement (Agreement) is entered into between the California Department of Fish and Wildlife (CDFW) and Reclamation District No. 17 (Permittee) as represented by Christopher Neudeck.

RECITALS

WHEREAS, pursuant to Fish and Game Code (FGC) section 1602, Permittee notified CDFW on December 3, 2014 that Permittee intends to complete the project described herein.

WHEREAS, pursuant to FGC section 1603, CDFW has determined that the project could substantially adversely affect existing fish or wildlife resources and has included measures in the Agreement necessary to protect those resources.

WHEREAS, Permittee has reviewed the Agreement and accepts its terms and conditions, including the measures to protect fish and wildlife resources.

NOW THEREFORE, Permittee agrees to complete the project in accordance with the Agreement

PROJECT LOCATION

The Reclamation District No. 17 (RD 17) Phase 3 Levee Seepage Area Project, Element IVc (Project), is located at the San Joaquin River, in San Joaquin County, State of California; Latitude 37.815230, Longitude -121.318225. The Project area is located along two sections of the RD 17 levee system on the San Joaquin River, west of I-5 in the City of Lathrop and is identified in the attached exhibits as Element IVc (see Exhibits A and B).

PROJECT DESCRIPTION

The Project is limited to the following actions (See Exhibit B):

Degrade existing levee waterside slope. A 410 linear foot section of the waterside slope of the existing levee along the San Joaquin River will be excavated to a point no lower than the mean high water mark. The degraded levee will allow high water to enter a new landside setback levee swale area between the existing levee and a new setback levee. The swale will be constructed to reduce the potential for fish stranding or entrapment in the setback area when river flows overtop the existing degraded levee, which will then allow drainage upon receding of the high water.

The existing levee will be fully restored at the tie-in points to the new setback levee where fill benching is required. The excavated levee material will be placed on top of the new setback levee.

Placement of rock slope protection along the San Joaquin River bank. Rock slope protection (riprap) will be placed on the waterside of the existing levee in three locations to reduce bank erosion during high flow periods, including two areas where the river would overtop the existing levee, which is to be degraded, during high flows, and another portion of the levee needing repair.

Approximately 1.136 acre of 18-inch quarry stone will be used for rock slope protection. Any disturbed existing riprap will be supplemented to ensure a uniform layer across the connection points with the new setback levee. The footprint of the degraded levee would be hydroseeded with native annual grasses.

Construction equipment to be used for the Project include dump trucks, scrapers, excavators, graders, trenchers, and bulldozers. Landside staging areas and existing access roads will be used for the Project.

PROJECT IMPACTS

Existing fish or wildlife resources the project could substantially adversely affect include: Spring-run Chinook Salmon (*Oncorhynchus tshawytscha*), Winter-run Chinook Salmon (*O. tshawytscha*), and Pacific pond turtle (*Clemmys marmorata*).

The adverse effects the project could have on the fish or wildlife resources identified above include: loss of bank stability, siltation and turbidity due to bank erosion during construction or riprap entering the water, and disturbance to nesting birds and other wildlife from construction activity.

As designed, the Project activities will occur above the mean high water line. The rock slope protection and degraded levee area will result in the permanent removal of 0.89

acre of ruderal and annual grassland. No riparian vegetation or trees on the waterside of the levee will be removed.

MEASURES TO PROTECT FISH AND WILDLIFE RESOURCES

1. Administrative Measures

Permittee shall meet each administrative requirement described below.

1.1 Documentation at Project Site. Permittee shall make the Agreement, any extensions and amendments to the Agreement, and all related notification materials and California Environmental Quality Act (CEQA) documents, readily available at the project site at all times and shall be presented to CDFW personnel, or personnel from another state, federal, or local agency upon request.

1.2 Providing Agreement to Persons at Project Site. Permittee shall provide copies of the Agreement and any extensions and amendments to the Agreement to all persons who will be working on the project at the project site on behalf of Permittee, including but not limited to contractors, subcontractors, inspectors, and monitors.

1.3 Notification of Conflicting Provisions. Permittee shall notify CDFW if Permittee determines or learns that a provision in the Agreement might conflict with a provision imposed on the project by another local, state, or federal agency. In that event, CDFW shall contact Permittee to resolve any conflict.

1.4 Project Site Entry. Permittee agrees that CDFW personnel may enter the project site at any time to verify compliance with the Agreement.

1.5 Notify CDFW of Project Modifications. All work shall be done according to the Notification and supporting materials received by CDFW, unless otherwise noted in this Agreement. The Permittee shall notify CDFW of any modifications made to the plans submitted to CDFW. Modifications to the project description may require an Amendment to this Agreement, and the Permittee shall not implement the proposed changes until CDFW has responded to the submitted changes.

1.6 Designated Biologist. At least 30 days before initiating project activities, Permittee shall obtain the CDFW's written approval for a Designated Biologist and all other biologists monitoring project activities (see Reporting Measure 3.3). The Designated Biologist or other approved biologist will be on site during ground disturbance activities.

2. Avoidance and Minimization Measures

To avoid or minimize adverse impacts to fish and wildlife resources identified above, Permittee shall implement each measure listed below.

2.1 Work Period. All project work shall be limited to the period between August 1 and November 30. Permittee shall conduct waterside levee construction activities as described in the Project Notification, above the mean high water mark.

2.2 Education Program. Permittee shall conduct a worker environmental awareness training for all persons employed or otherwise working on the Project site prior to performing any work at the project site. The program shall consist of a presentation made by the Designated Biologist that includes a discussion of the biology of the species and habitats identified in this Agreement. The Biologist shall also include as part of the education program information about the distribution and habitat needs of any special status species that may be present, legal protections for those species, penalties for violations and project-specific protective measures included in this Agreement. Interpretation shall be provided for non-English speaking workers. Upon completion of the education program, employees shall sign a form stating they attended the program and understand all protection measures. These forms shall be filed at the worksite and be available to CDFW upon request. The Permittee shall be responsible for ensuring compliance with all measures required by this Agreement.

2.3 Pacific Pond Turtle Pre-Construction Surveys and Avoidance. The Designated biologist shall conduct a pre-construction survey for the Pacific pond turtle prior to project activities. All survey results shall be sent to CDFW at the contact information below (see Reporting Measure 3.4). If a Pacific pond turtle is observed in the project area, it should be left alone to move out of the area on its own or may be relocated by an approved biologist to a suitable aquatic habitat at least 50 feet downstream of the construction area.

2.4 Removal of Riparian Vegetation and Trees. Disturbance or removal of riparian vegetation and trees is prohibited. Should riparian vegetation removal or tree trimming or removal be required CDFW must be notified at the contact information below prior to removal/trimming. CDFW at that time may require additional measures to protect wildlife and mitigation measures for affected wildlife or habitat.

2.5 Equipment, Hazardous Materials, Storage and Staging Areas. Permittee shall locate staging and storage areas for equipment, materials, fuels, lubricants, and solvents outside the waterway and adjacent banks. Stationary equipment such as motors, pumps, generators, compressors and welders, located within or adjacent to the channel shall be positioned over drip-pans. Vehicles must be moved away from the channel prior to refueling and lubrication. Permittee shall not stockpile or store construction material where it could be washed into the waterway or where it would cover aquatic or riparian vegetation.

2.6 Spill Prevention. The Permittee shall implement standard best management practices (BMPs) related to spill prevention and spill response measures in and around the project area.

2.7 Erosion Control Best Management Practices. Construction best management practices (BMPs) shall be implemented for the project activities. All exposed/disturbed areas within the project site shall be stabilized to the greatest extent possible. At no time shall silt, earthen fill material, or riprap be allowed to enter the river.

2.8 Trash Abatement. The Permittee shall not dump any litter or debris within the stream zone. All debris and waste shall be picked up daily and properly disposed of at an appropriate site. All construction debris and associated materials shall be removed from the work site upon project completion.

3. Reporting Measures

Permittee shall meet each reporting requirement described below.

3.1 Notification of Work Initiation/Completion. The Permittee shall notify CDFW in writing or by email at the CDFW contact information below at least 48 hours prior to the initiation, and following completion, of work.

3.2 Photo Documentation. Prior to project construction activities and upon completion of project construction activities the Permittee shall photograph the project site. Labeled copies of the photographs shall be sent to CDFW within 30 days of completion of the project. Photographs shall be submitted via email or post mail to the CDFW contact information below.

3.3 Biologist Approval. At least 30 days prior to initiation of work or pre-construction biological surveys, the Permittee shall submit to CDFW at the contact information below for written approval the resumes of the Designated Biologist and all other biologists working on the project.

3.4 Biological Pre-Construction Survey Results. The results of biological surveys shall be submitted to CDFW at the contact information below within 5 days of each survey and prior to commencement of work.

3.5 Special Status Species Documentation. If any species covered by this Agreement are observed, the Permittee shall immediately contact CDFW. Permittee shall also submit California Natural Diversity Data Base (CNDDB) forms to the CNDDB for all survey data within 15 working days of the sightings, and provide CDFW with copies of the CNDDB forms and survey maps. See http://www.dfg.ca.gov/biogeodata/cnddb for additional information.

3.6 Notification of Spill. In the event of a spill into the waters of the State, the Permittee shall immediately notify the California Emergency Management Agency at 1-800-852-7550 and immediately initiate the clean-up activities. CDFW shall be notified by the Permittee at the contact information below and consulted regarding clean-up procedures. Project operations shall not resume until the situation is remedied.

CONTACT INFORMATION

Any communication that Permittee or CDFW submits to the other shall be in writing and any communication or documentation shall be delivered to the address below by U.S. mail, fax, or email, or to such other address as Permittee or CDFW specifies by written notice to the other.

To Permittee:

Christopher Neudeck
Reclamation District No. 17
c/o Kjeldsen, Sinnock & Neudeck
711 N. Pershing Avenue
Stockton, CA 95203
Fax (209) 946-0296
Office (209) 946-0268
Email cneudeck@ksninc.com

To CDFW:

California Department of Fish and Wildlife
Bay Delta Region
7329 Silverado Trail
Napa, California 94558
Attn: Lake and Streambed Alteration Program – Ms. Crystal Spurr, Senior Environmental Scientist (Supervisory)
Notification #1600-2014-0424-R3
Fax (707) 944-5553
Office (209) 234-3442
Email crystal.spurr@wildlife.ca.gov

LIABILITY

Permittee shall be solely liable for any violations of the Agreement, whether committed by Permittee or any person acting on behalf of Permittee, including its officers, employees, representatives, agents or contractors and subcontractors, to complete the project or any activity related to it that the Agreement authorizes.

This Agreement does not constitute CDFW's endorsement of, or require Permittee to proceed with the project. The decision to proceed with the project is Permittee's alone.

SUSPENSION AND REVOCATION

CDFW may suspend or revoke in its entirety the Agreement if it determines that Permittee or any person acting on behalf of Permittee, including its officers, employees, representatives, agents, or contractors and subcontractors, is not in compliance with the Agreement.

Before CDFW suspends or revokes the Agreement, it shall provide Permittee written notice by certified or registered mail that it intends to suspend or revoke. The notice shall state the reason(s) for the proposed suspension or revocation, provide Permittee an opportunity to correct any deficiency before CDFW suspends or revokes the Agreement, and include instructions to Permittee, if necessary, including but not limited to a directive to immediately cease the specific activity or activities that caused CDFW to issue the notice.

ENFORCEMENT

Nothing in the Agreement precludes CDFW from pursuing an enforcement action against Permittee instead of, or in addition to, suspending or revoking the Agreement.

Nothing in the Agreement limits or otherwise affects CDFW's enforcement authority or that of its enforcement personnel.

OTHER LEGAL OBLIGATIONS

This Agreement does not relieve Permittee or any person acting on behalf of Permittee, including its officers, employees, representatives, agents, or contractors and subcontractors, from obtaining any other permits or authorizations that might be required under other federal, state, or local laws or regulations before beginning the project or an activity related to it.

This Agreement does not relieve Permittee or any person acting on behalf of Permittee, including its officers, employees, representatives, agents, or contractors and subcontractors, from complying with other applicable statutes in the FGC including, but not limited to, FGC sections 2050 et seq. (threatened and endangered species), 3503 (bird nests and eggs), 3503.5 (birds of prey), 5650 (water pollution), 5652 (refuse disposal into water), 5901 (fish passage), 5937 (sufficient water for fish), and 5948 (obstruction of stream).

Nothing in the Agreement authorizes Permittee or any person acting on behalf of Permittee, including its officers, employees, representatives, agents, or contractors and subcontractors, to trespass.

AMENDMENT

CDFW may amend the Agreement at any time during its term if CDFW determines the amendment is necessary to protect an existing fish or wildlife resource.

Permittee may amend the Agreement at any time during its term, provided the amendment is mutually agreed to in writing by CDFW and Permittee. To request an amendment, Permittee shall submit to CDFW a completed CDFW "Request to Amend Lake or Streambed Alteration" form and include with the completed form payment of the corresponding amendment fee identified in CDFW's current fee schedule (see Cal. Code Regs., tit. 14, § 699.5).

TRANSFER AND ASSIGNMENT

This Agreement may not be transferred or assigned to another entity, and any purported transfer or assignment of the Agreement to another entity shall not be valid or effective, unless the transfer or assignment is requested by Permittee in writing, as specified below, and thereafter CDFW approves the transfer or assignment in writing.

The transfer or assignment of the Agreement to another entity shall constitute a minor amendment, and therefore to request a transfer or assignment, Permittee shall submit to CDFW a completed CDFW "Request to Amend Lake or Streambed Alteration" form and include with the completed form payment of the minor amendment fee identified in CDFW's current fee schedule (see Cal. Code Regs., tit. 14, § 699.5).

EXTENSIONS

In accordance with FGC section 1605(b), Permittee may request one extension of the Agreement, provided the request is made prior to the expiration of the Agreement's term. To request an extension, Permittee shall submit to CDFW a completed CDFW "Request to Extend Lake or Streambed Alteration" form and include with the completed form payment of the extension fee identified in CDFW's current fee schedule (see Cal. Code Regs., tit. 14, § 699.5). CDFW shall process the extension request in accordance with FGC 1605(b) through (e).

If Permittee fails to submit a request to extend the Agreement prior to its expiration, Permittee must submit a new notification and notification fee before beginning or continuing the project the Agreement covers (Fish & G. Code, § 1605, subd. (f)). .

EFFECTIVE DATE

The Agreement becomes effective on the date of CDFW's signature, which shall be: 1) after Permittee's signature; 2) after CDFW complies with all applicable requirements under the California Environmental Quality Act (CEQA); and 3) after payment of the applicable FGC section 711.4 filing fee listed at http://www.wildlife.ca.gov/habcon/ceqa/ceqa_changes.html.

TERM

This Agreement shall expire on **December 31, 2019**, unless it is terminated or extended before then. All provisions in the Agreement shall remain in force throughout its term. Permittee shall remain responsible for implementing any provisions specified herein to protect fish and wildlife resources after the Agreement expires or is terminated, as FGC section 1605(a)(2) requires.

EXHIBITS

The documents listed below are included as exhibits to the Agreement and incorporated herein by reference.

EXHIBIT A – Project Location (Element IVc)
EXHIBIT B – Project (Element IVc) Features

AUTHORITY

If the person signing the Agreement (signatory) is doing so as a representative of Permittee, the signatory hereby acknowledges that he or she is doing so on Permittee's behalf and represents and warrants that he or she has the authority to legally bind Permittee to the provisions herein.

AUTHORIZATION

This Agreement authorizes only the project described herein. If Permittee begins or completes a project different from the project the Agreement authorizes, Permittee may be subject to civil or criminal prosecution for failing to notify CDFW in accordance with FGC section 1602.

CONCURRENCE

The undersigned accepts and agrees to comply with all provisions contained herein.

Complete EACH field, unless otherwise indicated, following the enclosed instructions and submit ALL required enclosures. Attach additional pages, if necessary.

1. APPLICANT PROPOSING PROJECT

Name	Christopher Neudeck		
Business/Agency	Reclamation District No. 17 (RD 17) c/o Kjeldsen, Sinnock & Neudeck		
Street Address	711 N. Pershing Avenue		
City, State, Zip	Stockton, CA 95203		
Telephone	209-946-0268	Fax	209-946-0296
Email	cneudeck@ksninc.com		

2. CONTACT PERSON (*Complete only if different from applicant*)

Name	Eric Htain, AECOM		
Street Address	2020 L Street, Suite 400		
City, State, Zip	Sacramento, CA 95811		
Telephone	916-414-5800	Fax	916-414-5850
Email	eric.htain@aecom.com		

3. PROPERTY OWNER (*Complete only if different from applicant*)

Name	See Attachment A for a list of owners of properties that adjoin the project area and their addresses.		
Street Address			
City, State, Zip			
Telephone		Fax	
Email			

4. PROJECT NAME AND AGREEMENT TERM

A. Project Name	RD 17 Phase 3 Levee Seepage Area Project
B. Agreement Term Requested	☑ Regular (*5 years or less*) ☐ Long-term (*greater than 5 years*)

C. Project Term		D. Seasonal Work Period		E. Number of Work Days
Beginning (*year*)	Ending (*year*)	Start Date (*month/day*)	End Date (*month/day*)	
2015	2017	May	November	552

NOTIFICATION OF LAKE OR STREAMBED ALTERATION

5. AGREEMENT TYPE

Check the applicable box. If box B, C, D, or E is checked, complete the specified attachment.		
A.	☑ Standard *(Most construction projects, excluding the categories listed below)*	
B.	☐ Gravel/Sand/Rock Extraction (*Attachment A*)	*Mine I.D. Number:* ____
C.	☐ Timber Harvesting (*Attachment B*)	THP *Number:* ____
D.	☐ Water Diversion/Extraction/Impoundment (*Attachment C*)	*SWRCB Number:* ____
E.	☐ Routine Maintenance (*Attachment D*)	
F.	☐ CDFW Fisheries Restoration Grant Program (FRGP)	*FRGP Contract Number* ____
G.	☐ Master	
H.	☐ Master Timber Harvesting	

6. FEES

Please see the current fee schedule to determine the appropriate notification fee. Itemize each project's estimated cost and corresponding fee. ***Note: The Department may not process this notification until the correct fee has been received.***

	A. Project	B. Project Cost	C. Project Fee
1	Placement of rock slope protection on San Joaquin river bank (Element IVc)	$125,000	$1,351.50
2			
3			
4			
5			
		D. Base Fee *(if applicable)*	
		E. TOTAL FEE ENCLOSED	$1,351.50

7. PRIOR NOTIFICATION OR ORDER

A. Has a notification previously been submitted to, or a Lake or Streambed Alteration Agreement previously been issued by, the Department for the project described in this notification?

☐ Yes (*Provide the information below*) ☑ No

Applicant: ____ Notification Number: ____ Date: ____

B. Is this notification being submitted in response to an order, notice, or other directive ("order") by a court or administrative agency (including the Department)?

☑ No ☐ Yes (*Enclose a copy of the order, notice, or other directive. If the directive is not in writing, identify the person who directed the applicant to submit this notification and the agency he or she represents, and describe the circumstances relating to the order.*)

☐ *Continued on additional page(s)*

8. PROJECT LOCATION

A. Address or description of project location.
(*Include a map that marks the location of the project with a reference to the nearest city or town, and provide driving directions from a major road or highway*)

The project location is not associated with a street address. The proposed project area is located along various sections of the RD 17 levee system in San Joaquin County, starting near the southern boundary of the City of Stockton, through the City of Lathrop, and to the western boundary of the City of Manteca. This includes portions of the San Joaquin River east levee and portions of the levee along the north bank of Walthall Slough. See Attachment A, Exhibits 1 and 2 for maps of RD 17 and the project elements.

From Sacramento, take Interstate 5 south past Stockton to the West Mathews Road exit. Travel west on West Mathews Road. Veer left onto Howard Road. The northernmost project elements are located where Howard Road crosses the San Joaquin River east levee. All other reaches are south of this location, along the San Joaquin River and Walthall Sough.

☐ *Continued on additional page(s)*

B. River, stream, or lake affected by the project. San Joaquin River

C. What water body is the river, stream, or lake tributary to? San Joaquin River

D. Is the river or stream segment affected by the project listed in the state or federal Wild and Scenic Rivers Acts? ☐ Yes ☑ No ☐ Unknown

E. County San Joaquin

F. USGS 7.5 Minute Quad Map Name	G. Township	H. Range	I. Section	J. ¼ Section
Lathrop	1S and 2S	6E	NA	NA

10. PROJECT DESCRIPTION

A. Describe the project in detail. Photographs of the project location and immediate surrounding area should be included.
- Include any structures (e.g., rip-rap, culverts, or channel clearing) that will be placed, built, or completed in or near the stream, river, or lake.
- Specify the type and volume of materials that will be used.
- If water will be diverted or drafted, specify the purpose or use.

Enclose diagrams, drawings, plans, and/or maps that provide all of the following: site specific construction details; the dimensions of each structure and/or extent of each activity in the bed, channel, bank or floodplain; an overview of the entire project area (i.e., "bird's-eye view") showing the location of each structure and/or activity, significant area features, and where the equipment/machinery will enter and exit the project area.

The proposed project is a levee flood risk reduction project involving use of cutoff walls, seepage berms, chimney drains, and engineering techniques to address existing levee flood risks. See Attachment A, Notification Continuation, for a more detailed project description.

☑ *Continued on additional page(s)*

B. Specify the equipment and machinery that will be used to complete the project.

Specific equipment to be used for the project will be determined by the construction contractor. Types of equipment anticipated to be used include: dump trucks for delivery/hauling, excavator, dozer, grader, loader, trencher, roller, heavy duty water tank truck, and pickup trucks.

☐ *Continued on additional page(s)*

C. Will water be present during the proposed work period (specified in box 4.D) in the stream, river, or lake (specified in box 8.B).	☑ Yes ☐ No (*Skip to box 11*)
D. Will the proposed project require work in the wetted portion of the channel?	☐ Yes (*Enclose a plan to divert water around work site*) ☑ No

NOTIFICATION OF LAKE OR STREAMBED ALTERATION

11. PROJECT IMPACTS

A. Describe impacts to the bed, channel, and bank of the river, stream, or lake, and the associated riparian habitat. Specify the dimensions of the modifications in length (linear feet) and area (square feet or acres) and the type and volume of material (cubic yards) that will be moved, displaced, or otherwise disturbed, if applicable.

See Attachment A, Notification Continuation, for a complete description of project activities and impacts.

☑ *Continued on additional page(s)*

B. Will the project affect any vegetation? ☑ Yes (*Complete the tables below*) ☐ No

Vegetation Type	Temporary Impact	Permanent Impact
Annual grassland (on waterside slope of levee)	Linear feet: 0 Total area: 0	Linear feet: 850 Total area: 0.89 acre
	Linear feet: Total area:	Linear feet: Total area:

Tree Species	Number of Trees to be Removed	Trunk Diameter (range)

☐ *Continued on additional page(s)*

C. Are any special status animal or plant species, or habitat that could support such species, known to be present on or near the project site?

☑ Yes *(List each species and/or describe the habitat below)* ☐ No ☐ Unknown

See Attachment A, Notification Continuation, for more information on special-status species with potential to occur in the project area.

☑ *Continued on additional page(s)*

D. Identify the source(s) of information that supports a "yes" or "no" answer above in Box 11.C.

Draft EIS/EIR prepared for the project (see CD provided as Attachment B).

☑ *Continued on additional page(s)*

E. Has a biological study been completed for the project site?

☑ Yes (*Enclose the biological study*) ☐ No

Note: A biological assessment or study may be required to evaluate potential project impacts on biological resources.

F. Has a hydrological study been completed for the project or project site?

☐ Yes (*Enclose the hydrological study*) ☑ No

Note: A hydrological study or other information on site hydraulics (e.g., flows, channel characteristics, and/or flood recurrence intervals) may be required to evaluate potential project impacts on hydrology.

12. MEASURES TO PROTECT FISH, WILDIFE, AND PLANT RESOURCES

A. Describe the techniques that will be used to prevent sediment from entering watercourses during and after construction.

See Attachment A, Notification Continuation, for a description of measures to ensure control of erosion and sedimentation resulting from the project.

☑ *Continued on additional page(s)*

B. Describe project avoidance and/or minimization measures to protect fish, wildlife, and plant resources.

See the Draft EIS/EIR and Biological Assessment (see CD provided as Attachment B) for discussion of measures to protect fish, wildlife, and plant resources.

☑ *Continued on additional page(s)*

C. Describe any project mitigation and/or compensation measures to protect fish, wildlife, and plant resources.

The Draft EIS/EIR (see CD provided as Attachment B) prepared for the project includes a number of mitigation measures to avoid, minimize, and compensate for potential impacts on special-status fish, wildlife and plant resources .

Because impacts on areas of CDFW jurisdiction would be limited to 0.89 acres of grassland on the waterside slope of the San Joaquin River east levee and no loss of CDFW jurisdictional riparian vegetation or other important fish or wildlife habitat would occur, no compensatory mitigation for this impact is proposed.

☑ *Continued on additional page(s)*

13. PERMITS

List any local, state, and federal permits required for the project and check the corresponding box(es). Enclose a copy of each permit that has been issued.

A. See Table 3 in Attachment A for a complete list of permits applied for. ☑ Applied ☐ Issued

B. ______ ☑ Applied ☐ Issued

C. ______ ☑ Applied ☐ Issued

D. Unknown whether ☐ local, ☐ state, or ☐ federal permit is needed for the project. (*Check each box that applies*)

☑ *Continued on additional page(s)*

14. ENVIRONMENTAL REVIEW

A. Has a draft or final document been prepared for the project pursuant to the California Environmental Quality Act (CEQA), National Environmental Protection Act (NEPA), California Endangered Species Act (CESA) and/or federal Endangered Species Act (ESA)?

☑ Yes *(Check the box for each CEQA, NEPA, CESA, and ESA document that has been prepared and enclose a copy of each)*

☐ No *(Check the box for each CEQA, NEPA, CESA, and ESA document listed below that will be or is being prepared)*

☐ Notice of Exemption	☐ Mitigated Negative Declaration	☑ NEPA document (*type*): DEIS
☐ Initial Study	☑ Environmental Impact Report	☐ CESA document (*type*):
☐ Negative Declaration	☐ Notice of Determination *(Enclose)*	☑ ESA document (*type*): Biological Assessment
☐ THP/ NTMP	☐ Mitigation, Monitoring, Reporting Plan	

B. State Clearinghouse Number (*if applicable*)	2010042073
C. Has a CEQA lead agency been determined?	☑ Yes (*Complete boxes D, E, and F*) ☐ No (*Skip to box 14.G*)
D. CEQA Lead Agency	RD 17
E. Contact Person	Christopher Neudeck
F. Telephone Number	209-946-0268

G. If the project described in this notification is part of a larger project or plan, briefly describe that larger project or plan.

RD 17 is currently undertaking a program of levee improvements at various locations along the San Joaquin River east levees. The overall purpose of the RD 17 Phase 3 Levee Seepage Area Project (the RD 17 LSAP) is to increase the levee system's resistance to underseepage and through seepage. The RD 17 LSAP consists of three phases. RD 17 has completed the Phase 1 and Phase 2 projects. The project described in this notification, Phase 3 of the RD 17 LSAP, is the last of the three project phases.

☐ *Continued on additional page(s)*

H. Has an environmental filing fee (Fish and Game Code section 711.4) been paid?

☐ Yes (*Enclose proof of payment*) ☑ No (*Briefly explain below the reason a filing fee has not been paid*)

A filing fee has not yet been paid because the Final EIR is still in preparation. Certification of the Final EIR is anticipated for January or February 2015. A copy of the proof of payment of the fee will be sent to CDFW upon certification and payment of the filing fee.

Note: If a filing fee is required, the Department may not finalize a Lake or Streambed Alteration Agreement until the filing fee is paid.

15. SITE INSPECTION

Check one box only.

☐ In the event the Department determines that a site inspection is necessary, I hereby authorize a Department representative to enter the property where the project described in this notification will take place at any reasonable time, and hereby certify that I am authorized to grant the Department such entry.

☑ I request the Department to first contact (*insert name*) Christopher Neudeck at (*insert telephone number*) 209-946-0268 to schedule a date and time to enter the property where the project described in this notification will take place. I understand that this may delay the Department's determination as to whether a Lake or Streambed Alteration Agreement is required and/or the Department's issuance of a draft agreement pursuant to this notification.

16. DIGITAL FORMAT

Is any of the information included as part of the notification available in digital format (i.e., CD, DVD, etc.)?

☑ Yes (Please enclose the information via digital media with the completed notification form)

☐ No

17. SIGNATURE

I hereby certify that to the best of my knowledge the information in this notification is true and correct and that I am authorized to sign this notification as, or on behalf of, the applicant. I understand that if any information in this notification is found to be untrue or incorrect, the Department may suspend processing this notification or suspend or revoke any draft or final Lake or Streambed Alteration Agreement issued pursuant to this notification. I understand also that if any information in this notification is found to be untrue or incorrect and the project described in this notification has already begun, I and/or the applicant may be subject to civil or criminal prosecution. I understand that this notification applies only to the project(s) described herein and that I and/or the applicant may be subject to civil or criminal prosecution for undertaking any project not described herein unless the Department has been separately notified of that project in accordance with Fish and Game Code section 1602 or 1611.

Christopher H. Neudeck — 11/20/17

Signature of Applicant or Applicant's Authorized Representative — Date

BOX 10: PROJECT DESCRIPTION

RD 17 is responsible for levee operation and maintenance along the east side of the San Joaquin River, the south side of French Camp Slough, the north side of Walthall Slough, and a dryland levee in an area ranging from the City of Stockton south to the City of Manteca (Exhibit 1, at end of this attachment). RD 17 is currently undertaking a program of levee improvements at various locations along the San Joaquin River east levee. The overall purpose of the RD 17 Levee Seepage Area Project (the RD 17 LSAP) is to increase the levee system's resistance to underseepage and through seepage. The RD 17 LSAP consists of three phases (Phases 1-3). RD 17 has completed the Phase 1 and Phase 2 Projects, and the currently proposed Phase 3 of the RD 17 LSAP (the Phase 3 Project) is the last of the three project phases.

The Phase 3 Project would address under seepage and/or through seepage concerns and repair and/or remediate levee geometry to USACE design standards along approximately 5.2 miles of the RD 17 levee system, including portions of the San Joaquin River east levee and portions of the levee along the northerly bank of Walthall Slough (Exhibit 2). Flood risk reduction improvements along the dryland levee portion of the RD 17 LSAP area are not planned as part of the Phase 3 Project; therefore RD 17 is not seeking authorization for this area at this time.

Levee Improvement Components

Levee improvements would consist primarily of in-place repair/remediation, but would also include a single setback levee at Element IVc. The Phase 3 Project's landside levee improvements include a combination of constructing seepage berms, installing chimney drains and cutoff walls, raising the landside grade, and constructing a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system. These levee improvement components, as well as additional project components, such as levee geometry corrections and stormwater management, are summarized in Table 2 and described in more detail below.

Table 2
Summary of Major Activities Proposed for each Element of the Reclamation District 17 Phase 3 Levee Seepage Area Project

Element	Type of Remediation	Proposed Activities
Ia	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and install a 590-foot-long seepage berm (minimum 65 feet wide) with chimney drain to meet required exit gradients.
Ib	under seepage and through seepage	Fill existing depression to 300 feet from toe of existing levee; place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width; and install a 125-foot-long seepage berm (minimum 60 feet wide) with chimney drain on top of fill to meet required exit gradients.
Ie, IIIb, IVa, and VIIb	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and construct seepage berms with lengths of 655 feet (Ie), 720 feet (IIIb), 525 feet (IVa), and 385 feet (VIIb), and chimney drains to meet required exit gradients. Minimum seepage berm widths would vary (65–105 feet) depending on the element. For Element Ie, construct v-ditch from seepage berm to existing swale.
IIa and IIb	under seepage and through seepage	Install cutoff wall with a length of 2,550 feet to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.
IVc	under seepage and through seepage	Construct 1,240-foot-long setback levee with seepage berm and cutoff wall to meet required exit gradients. Seepage berm would be a minimum of 65 feet wide. Install riprap on waterside of existing levee where it would intersect setback levee. After setback levee is completed, remove 400 linear feet of the existing levee on downstream side of oxbow. Construct fish release swale in setback area to drain to river through downstream opening in remnant levee.

Table 2 Summary of Major Activities Proposed for each Element of the Reclamation District 17 Phase 3 Levee Seepage Area Project		
Element	**Type of Remediation**	**Proposed Activities**
Va and VIa.1	under seepage and through seepage	Where feasible, place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and install cutoff walls with a length of 9,520 feet to meet required exit gradients. Depth of cutoff walls would vary from 60–85 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Open-cut method would be used for all cutoff walls.
IIIa	through seepage	Place levee fill material along landside of existing levee slopes where feasible to provide minimum 3:1 slopes and 20-foot levee crown widths and install chimney drain in existing 4,680-feet-long seepage berm to meet required exit gradients.
VIa.4	under seepage and through seepage	Install cutoff wall with length of 70 feet to meet required exit gradients. Depth of cutoff wall would vary from 90–100 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 26-foot levee crown width.
VIb, VIc, VId, and VIe	under seepage and through seepage	Install cutoff wall with length of 3,720 feet (VIbcde) to meet required exit gradients. Depth of cutoff wall would vary from 70–80 feet. Cutoff wall in levee prism would involve DSM construction, as well as, degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown.
VIIe	under seepage and through seepage	Install DSM cutoff wall with a length of 1,900 feet to meet required exit gradients. Depth of cutoff wall would vary from 60–120 feet. Deep slurry mixing method would be used. Plaee levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and levee crown width. Soil removed during levee degradation would be stockpiled on adjacent RD 17 property and used for rebuilding the levee at these locations or used for fill at other locations in the Phase 3 Project.
VIIg	under seepage and througb seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and construct seepage berm with chimney drain with length 395 feet to meet required exit gradients. Minimum seepage berm width would be 65 feet.
Source: Data provided by Kjeldsen, Sinnock & Neudeck, Inc. in 2014		

SEEPAGE BERMS

Reducing the risk of levee failure caused by both under seepage and through seepage may be addressed by constructing a drained seepage berm. A drained berm collects and conveys seepage, thereby reducing the flood risk associated with a high-water event. A drained seepage berm is built on the landside, adjacent to a levee, and consists of layers of sand filter material, drain rock, geosynthetic filter fabric, and a seepage berm soil fill.

The drained seepage berm reduces flood risk during sustained high-river-stage events by collecting seepage that otherwise would flow onto the landside ground surface at and beyond the landside toe of the levee slope, and then by conveying the seepage away from the levee. The layer of sand filter material placed on the natural ground surface serves to reduce the transmission of fine-grained soils into the drain rock, thereby maintaining the drain rock's ability to be a conductive soil unit that conveys collected seepage. Similarly, the filter fabric that separates the drain rock from the seepage berm fill soil prevents finer soils from migrating into the drain rock unit. The weight of the berm acts as ballast, reducing the potential for detrimental boils and piping.

The design width and height of a seepage berm are dependent on the relative permeability of the underlying soil layers and the amount of pressure head pushing water under the levee and through the near-surface soils during sustained high-river-stage events. The higher the water pressure head acting on the near-surface soils on the landside of the levee prism, the wider and/or deeper the seepage berm must be to reduce flood risk.

For the Phase 3 Project, drained seepage berm widths of 65–125 feet would be adequate to meet the design criteria in most cases. However, these types of berms may extend up to 300–400 feet inland of the landside toe of the levee. Seepage berms are typically constructed using select materials excavated from borrow sites or obtained from commercial sources. In the case of the Phase 3 Project, soil material would be purchased from commercial sources. A compacted-surface patrol road would be constructed near the outside edge of the seepage berm (see "Additional Project Components" below).

In urban areas, some seepage berms would also include a toe drain system (Element VIIg) or a V-ditch (Element Ie) to safely collect and discharge the seepage water into an urban storm drainage system. A toe drain pipe is a below-grade, perforated pipe surrounded by a layer of drain rock. The toe drain pipe is a mechanism to safely collect and convey seepage water away from the levee and seepage berm. If the toe drain pipe were unable to convey the seepage water, it would exit the seepage berm through the drain rock at the face of the berm similar to a nonurban berm.

Chimney Drains

Chimney drains are drainage systems that collect seepage waters that are flowing through the aboveground portion of the levee structure. These drains are used to collect and convey through seepage. A chimney drain consists of a 1- to 3-foot-thick layer of sand and drain rock. Filter fabric is placed between the soil and rock layer to avoid migration of the soil into the rock, which could clog the rock layer and reduce its ability to carry seepage flows. The chimney drain is placed directly on the landside slope of the levee and tied into an existing or new seepage berm at the landside base of the levee; the height of the proposed chimney drains would vary from 5 to 20 feet above the elevation of the landside levee toe. The chimney drain conveys the through seepage flows to a seepage berm, which is located at the landside base of the levee.

Installing a chimney drain in an existing seepage berm would involve adding the through seepage material on top of the existing seepage berm, and tying this material into the existing seepage berm material by excavating off the seepage berm fill material and physically tying the two drainage rock layers together. Where the remediation involves construction of a new seepage berm with a chimney drain, the chimney drain would be installed during construction of the new seepage berm.

Cutoff Walls

In selected locations of the Phase 3 Project, cutoff walls are being considered for placement within the levee prism (parallel to the river). Cutoff walls use specialized earthen materials (often bentonite clay, which has low permeability). Cutoff walls would be constructed vertically through the levee prism, extending into or through deeper foundational soils that have low-permeability soil (a layer through which seepage does not flow readily). Cutoff walls would thus significantly reduce the potential for under and through seepage flow during high-river-stage events. Two methods for installing cutoff walls would be used along portions of the RD 17 levees: the open-cut method and the deep slurry mixing method.

The open-cut method is used to install shallow cutoff walls to a maximum depth of approximately 80 feet. This method involves excavating material in an open trench (the trench is filled with a bentonite slurry to maintain the side slopes of the excavation) and then replacing it with the select materials, typically a bentonite or cement-bentonite slurry. In this case, the top one-third to one-half of the levee height is "degraded," meaning that it is excavated to ensure that any weakness in the narrow upper portion of the levee would not fail during construction.

For the deep slurry mixing method, specialized equipment is used to excavate deep into the subsurface, allowing the cutoff walls to reach depths of up to 120 feet. The deep slurry mixing method involves mixing a soil-cement-bentonite mixture and replacing material as it is excavated during construction of the cutoff wall, thereby reducing the risk of failure during construction. This method does not require levee crown degradation.

Cutoff walls would be extended approximately 300 feet beyond the element boundary to provide the required overlap when seepage berms have been or are being installed along the landside of adjacent levee elements. Levee slopes where cutoff walls would be installed would also be modified as needed to achieve the required 3:1 slope.

Setback Levee with Seepage Berm and Underlying Cutoff Wall

A setback levee is a levee constructed some distance behind an existing levee. The setback is tied into the existing levee at the upstream and downstream ends of the setback area. All or a portion of the existing levee between these two points is then typically removed to allow high-water events to inundate the newly expanded floodway. Soil from the old levee may be used as a source of fill for other flood protection improvement projects, depending on the quality and quantity of material generated from demolition of the old levee. In some cases, it may be necessary to continue maintaining the existing levee after a setback levee is constructed (e.g., to protect existing development in the setback area) and to use the newly constructed levee as a backup levee.

In the Phase 3 Project area, soil materials below a setback levee are anticipated to have properties similar to those of materials below the existing levees. Therefore, a setback levee would have no seepage-related benefit in the RD 17 area relative to other seepage control methods, and like the existing levees, a setback levee would require either a cutoff wall or seepage berm to sufficiently reduce the potential negative impacts of under seepage flows. Nonetheless, implementing a setback levee could provide some additional capacity in the river for floodwaters, and would also have the potential to provide environmental habitat in the area between the new and old levee locations. In the Phase 3 Project area, any newly expanded floodway created by a proposed setback levee would be designed to drain surface water after a high-water event to prevent fish stranding. A setback levee with a seepage berm and an underlying cutoff wall is proposed for construction in Element IVc.

Raised Landside Grade

Directly adjacent to the landside toe of the levee in Element Ib, there is an approximately 5-foot-deep depression that was used as a borrow site to facilitate construction of the Howard Road Bridge. RD 17 will place fill within this depression to raise the landside grade.

Additional Project Components

The following additional activities would occur as part of the Phase 3 Project:

- **Levee geometry corrections:** Many Phase 3 Project elements do not currently meet requirements for levee geometry (i.e., slopes, crown width). To correct levee geometry, levee fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot-wide levee crown.

- **O&M access and utility corridors:** A 20-foot-wide permanent O&M access corridor would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.

- **Temporary construction easements:** Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the sites returned to preproject conditions at the end of construction.

- **Stormwater management:** Drainage swales would be constructed around the outside of levee improvements, where needed, and other stormwater best management practices (BMPs) would be implemented to manage stormwater runoff during and after construction.

- **Right-of-way acquisition:** Lands within the Phase 3 Project footprint would be acquired as needed to accommodate levee improvements (e.g., seepage berms, setback levees) and establish the minimum 20-foot-wide O&M access corridor at the landside toes of all the improved levees, to prevent encroachment into the levee or seepage berm improvements. Privately owned lands would be acquired in fee but may be taken as easements if needed. Where the RD 17 project footprint would overlie land owned and managed by other agencies (i.e., the City of Lathrop, San Joaquin County, Union Pacific Railroad [UPRR]), either the land would have to be acquired in fee or easements would have to be obtained and secured. Real property acquisition and any relocation services (if needed—no relocations are anticipated) would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 USC 4601 et seq.) and implementing regulation, Title 49 of CFR Part 24, and California Government Code Section 7267 et seq.

- **Haul roads:** An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and concrete) would be required to construct these levee improvements. These materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Phase 3 Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would include public roadways, on and within 300 feet of the levees; existing unpaved roads used for access to work areas; and levee patrol roads atop the levee crown.

- **Landside vegetation removal:** Landside vegetation within the footprint of the proposed levee improvements, including maintenance roadway corridors and temporary access easements, would be cleared to prepare for levee improvement work under the Phase 3 Project. These areas would be hydroseeded with a seed mix compliant with USACE levee vegetation criteria after construction activities are completed, and temporary construction easements would be returned to pre-project conditions. The proposed action would not involve performing any work on the waterside of the levee; therefore, no waterside vegetation would be removed.

- **Encroachment management:** Several features are within the Phase 3 Project footprint: power poles, overhead and underground utilities, and a variety of agriculture-related items (e.g., irrigation and drainage infrastructure, fences). Utility infrastructure (power poles) would be relocated as needed to accommodate the levee improvements, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Phase 3 Project area would be removed or relocated as required to meet the criteria of USACE, the CVFPB, and FEMA.

BOX 11: PROJECT IMPACTS

CDFW JURISDICTION WITHIN THE PROJECT AREA

AECOM wetland ecologists conducted wetland delineations within the RD 17 Phase 3 Project area on November 3, 2009, December 21, 2009, July 1, 2010, and again on February 13, 2014. The multiple delineations were required due to revisions and changes in the footprint of the project to ensure the project design meets current USACE standards. The USACE issued Preliminary Jurisdictional Determinations for the project on November 10, 2009, April 9, 2010, October 21, 2010, and again on April 7, 2014.

The Wetland Delineation Report and observations made during associated field surveys were used to determine CDFW jurisdiction. The only portion of the project site determined to be under CDFW jurisdiction is the San Joaquin River.

Additional aquatic features and vegetation that are present on the land side of the San Joaquin River east levee were determined not to qualify for CDFW jurisdiction, including a small area of freshwater marsh in Element Ib, several short ditch segments in Elements Ie, IVa, and Va–VIa.1, and a few scattered isolated trees and small clumps of trees in upland areas between the levee and adjacent agricultural fields and developed areas. The freshwater marsh is a small piece of a larger marsh (located outside the project area) between West Howard Road and an agricultural field to the south that is only connected to the San Joaquin River via pumping to and from irrigation and drainage ditches. The ditches in the project area function primarily as drainage ditches for the adjacent agricultural fields and are supplied with water from the San Joaquin River via runoff from irrigation of the adjacent agricultural fields. These isolated areas of wetland and upland vegetation on the land side of the levee provide small isolated patches of marginal quality wildlife habitat, but they are not associated with a riparian zone of the San Joaquin River or other feature under CDFW jurisdiction.

EFFECTS ON CDFW JURISDICTION

Exhibits 3 through 16 depict the project area associated with each element of the proposed project. Because CDFW jurisdiction within the project area is limited to the San Joaquin River, the only portion of the proposed project that would affect habitat under CDFW jurisdiction is in Element IVc (Exhibit 8). A setback levee is proposed at this bend in the river, rather than improving the existing levee. The setback levee would span the San Joaquin River east levee sections upstream and downstream of the river bend, along the eastern boundary of the project area. Most of the existing levee would remain, except for a 400-foot-long portion due west of the downstream end of the setback levee, which would be degraded. Degrading this portion of the levee would facilitate drainage of a swale that would be constructed in the area within the river bend, between the existing levee and the new setback levee (which would be considered the setback area). The swale would be constructed to reduce the potential for fish stranding or entrapment in the setback area when river flows overtop the levee and inundate the setback area. In addition, riprap would be placed along the waterside slope of the existing levee in three locations to reduce bank erosion during high flow periods, including the area where the river would likely overtop the existing levee in high flows and on each side of levee segment that would be degraded.

Degrading the levee segment and placing riprap would affect approximately 0.25 acre and 0.64 acre, respectively, on the waterside of the San Joaquin River east levee (Table 2). These effects would be permanent but are not anticipated to require removal of any riparian vegetation. The upstream area where riprap would be placed does not support any woody vegetation. The downstream area where the levee segment would be degraded and riprap would be placed is adjacent to a small patch of riparian vegetation on a bench above the ordinary high water mark. However, project activities would occur on the maintained levee slope above the bench, which does not support any woody vegetation. Therefore, although impact to these areas would be permanent, they would not result in loss of important habitat for fish or wildlife.

Table 3
Acreages of CDFW Jurisdiction that would be Permanently Affected by the Reclamation District 17 Phase 3 Levee Seepage Area Project

Proposed Levee Improvement	Habitat Type	Action	Acreage	Linear Feet
setback levee	annual grassland on maintained levee slope	Cut – levee degradation	0.25	400
		Fill – riprap placement	0.64	700
TOTAL PERMANENT EFFECTS TO CDFW JURISDICTION			**0.89**	**850[1]**

Note: [1] Levee degradation and riprap placement overlap for 250 linear feet.

EFFECTS ON SPECIAL STATUS SPECIES

Potential for the proposed project to affect special-status species was evaluated in the Draft Environmental Impact Statement/Environmental Impact Report (DEIS/DEIR) that was prepared and circulated for public comment and review in September 2011 (SCH # 2010042073). The public comment period has closed and RD 17 is in the process of completing the Final EIR for the project. It is anticipated that RD 17 will adopt the EIR in November 2014. In addition, a Biological Assessment has been completed to facilitate consultation under Section 7 of the Endangered Species Act between USACE Construction Operations (ConOps) Division and the U.S. Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS). USACE ConOps Division will initiate consultation with the USFWS for federally listed terrestrial and freshwater fish species that may be affected, and with the NMFS for federally listed anadromous fish species and essential fish habitat that may be affected by the proposed project. A copy of the public DEIS/DEIR and the Biological Assessment are included on the CD provided as Attachment C.

The DEIS/DEIR concludes that implementation of the proposed project could result in adverse effects to a number of special-status fish, plant, and terrestrial wildlife species. Federally and/or state-listed species that are known to occur or have the potential to occur in the Phase 3 Project area include: Delta button-celery (*Eryngium racemosum*), Mason's lilaeopsis (*Lilaeopsis masonii*), valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), Swainson's hawk (*Buteo swainsoni*), riparian brush rabbit (*Sylvilagus bachmani riparius*), delta smelt (*Hypomesus transpacificus*), longfin smelt *(Spirinchus thaleichthy)*,Central Valley steelhead distinct population segment (DPS) (*Oncorhyncus mykiss*), Sacramento River winter-run Chinook salmon ESU (*O. tshawytscha*), Central Valley spring-run Chinook salmon ESU (*O. tshawytscha*), and Southern DPS of North American green sturgeon (*Acipenser medirostris*). Central Valley fall-/late-fall-run Chinook salmon evolutionary significant unit (ESU) (*O. tshawytscha*) is not federally or state-listed but Essential Fish Habitat for this species occurs in the Phase 3 Project Area. Other federally and state-listed species such as vernal pool fairy shrimp (*Branchinecta lynchii*), vernal pool tadpole shrimp (*Lepidurus packardi*), California tiger salamander (*Ambystoma californiense*), giant garter snake (*Thamnophis gigas*), and California red-legged frog (*Rana draytonii*) are not likely to occur in the Phase 3 Project Area as no suitable habitat is present in the action area. Mitigation measures designed to avoid and reduce potential impacts on these species, and to compensate for unavoidable impacts, are identified in the DEIS/DEIR and would be implemented by RD17.

BOX 12: MEASURES TO PROTECT FISH, WILDLIFE, AND PLANT RESOURCES

Project designs have been iterative between the initial conceptual design and the 65% design stage currently available. The designs have been refined over time to include more specific information, but also to utilize smaller footprints and less disturbing engineering techniques, resulting in avoidance of adverse effects in some areas. In addition, the DEIR/DEIS analyzes project alternatives, including a maximum footprint alternative, which would have greater effects than the preferred alternative (proposed project). One major design change that reduces effects is the method for installation of the cutoff walls. Rather than conduct a traditional 1/3-levee degrade of the upper waterside and landside slopes of the levee to facilitate installation of the deep cutoff wall, RD 17 is proposing to degrade the levee through the crown road and within the middle portion of the levee prism, without any degrade of the waterside crown limit or waterside slope. This results in no disturbance of the waterside bank of the San Joaquin River to accommodate cutoff wall construction.

A number of BMPs would be implemented to minimize indirect impacts to the San Joaquin River, meet "maximum extent practicable" and "best conventional technology/best available technology" requirements, and to address compliance with water quality standards. A monitoring program shall be implemented during and after construction to ensure that the Phase 3 Project complies with all applicable standards and that the BMPs are effective. The project proponent will file a notice of intent with the Central Valley Regional Water Quality Control Board (RWQCB) to discharge stormwater associated with construction activity, and final design and construction specifications will require the implementation of standard erosion, siltation, and good housekeeping BMPs. In addition, construction contractors will be required to prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) and comply with the conditions of the National Pollutant Discharge Elimination System general stormwater permit for construction activity (Order No. 2009-0009-DWQ). The SWPPP would describe the construction activities to be conducted, BMPs that would be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that shall be conducted.

The SWPPP shall include the following:

- pollution prevention measures (erosion and sediment control measures and measures to control nonstormwater discharges and hazardous spills);
- demonstration of compliance with all applicable Central Valley RWQCB standards and other applicable water quality standards;
- demonstration of compliance with regional and local standards for erosion and sediment control;
- identification of responsible parties;
- checklists that document when maintenance inspections occurred, the results of the inspection, required corrective measures, and when corrective measures were implemented;
- detailed construction timelines; and
- a BMP monitoring and maintenance schedule.

BMPs shall include requirements to:

- conduct all work according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized;

- install silt fences near riparian areas or existing drainages to control erosion and trap sediment and reseed cleared areas with native vegetation;
- stabilize disturbed soils before the onset of the winter rainfall season;
- stabilize and protect soil stockpiles from exposure to rain and potential erosion;
- conduct maintenance on a regular basis to confirm proper installation and function of BMPs, and during storm events conduct maintenance daily ; and
- immediately repair and replace BMPs that have failed (within 48 hours of the storm event) with sufficient devices and materials (e.g., silt fence, coir rolls, erosion blankets) provided throughout project construction to enable immediate corrective action for failed BMPs.

The SWPPP also shall specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of adverse impacts from use or accidental spills or releases of contaminants. Specific measures applicable to the Phase 3 Project include, but are not limited to, the following:

- develop and implement strict on-site handling rules to keep potentially contaminating construction and maintenance materials out of drainages and other waterways;
- conduct all refueling and servicing of equipment with absorbent material or drip pans underneath to contain spilled fuel, oil, and other fluids; and collect any fluid drained from machinery during servicing in leak-proof containers and deliver to an appropriate disposal or recycling facility;
- maintain controlled construction staging and fueling areas at least 100 feet away from channels or wetlands to minimize accidental spills and runoff of contaminants in stormwater;
- prevent substances that could be hazardous to aquatic life from contaminating the soil or entering watercourses;
- maintain spill cleanup equipment in proper working condition. Clean up all spills immediately according to the spill prevention and response plan;
- develop a slurry spill contingency plan to respond to a potential for bentonite slurry spill and prevent slurry from entering watercourses; and
- immediately notify the California Department of Fish and Game and the Central Valley RWQCB of any spills and cleanup procedures.

BOX 13: PERMITS

Table 4 provides a complete list of additional state and federal permits and authorizations applicable to the proposed project and for which RD 17 has applied or will apply.

Table
Other Authorizations Applicable to the
Reclamation District 17 Phase 3 Levee Seepage Area Project

Agency	Permit/Authorization	Date Applied/Initiated
Central Valley Flood Protection Board	Encroachment Permit	
U.S. Army Corps of Engineers	Clean Water Act, Section 404 Permit	May 2014
U.S. Fish and Wildlife Service	Endangered Species Act, Section 7 consultation/biological opinion	
State Historic Preservation Officer	National Historic Preservation Act, Section 106 consultation and SHPO concurrence	
Regional Water Quality Control Board	Clean Water Act, Section 401 Certification	July 2014
	Clean Water Act, Section 402 NPDES Permit

SUBJECT: ***Filing of Notice of Determination pursuant to Public Resources Code section 21108***

State Clearinghouse Number: 2010042073

Project Title: Phase 3 RD 17 Levee Seepage Area Project (Lake or Streambed Alteration Agreement No. 1600-2014-0424-R3)

Project Location (include county): The Project is located along two sections of the Reclamation District No. 17 levee system on the San Joaquin River, west of I-5 in the City of Lathrop in San Joaquin County, State of California; Latitude 37.815230, Longitude -121.318225.

Project Description: The California Department of Fish and Wildlife (CDFW) has executed a Lake or Streambed Alteration Agreement, No.1600-2014-0424-R3, pursuant to section 1602 of the Fish and Game Code to Reclamation District No. 17, as represented by Christopher Neudeck.

The Project is limited to the following activities: One 410 linear foot section of the waterside slope of the existing levee along the San Joaquin River will be excavated to a point no lower than the mean high water mark. The degraded levee will allow high water to enter a new landside setback levee swale area between the existing levee and a new setback levee. The swale will be constructed to reduce the potential for fish stranding or entrapment in the setback area when river flows overtop the existing degraded levee, which will then allow drainage upon receding of the high water. Rock slope protection (riprap) will be placed on the waterside of the existing levee in three locations to reduce bank erosion during high flow periods, including two areas where the river would overtop the existing levee, which is to be degraded, during high flows, and another portion of the levee needing repair.

This is to advise that CDFW, acting as Responsible Agency approved the above described project on September 13, 2016 and has made the following determinations regarding the project pursuant to California Code of Regulations section 15096, subdivision (i):

1. The project will not have a significant effect on the environment.
2. An ☒ Environmental Impact Report / ☐ mitigated negative declaration was prepared for this project pursuant to the provisions of CEQA.
3. Mitigation measures ☒ were / ☐ were not made a condition of CDFW's approval of the project.
4. A mitigation reporting or monitoring plan ☒ was / ☐ was not adopted by CDFW for this project.
5. A statement of overriding considerations was not adopted by CDFW for this project.
6. Findings were not made by CDFW pursuant to California Code of Regulations section 15091.

   The ☒ environmental impact report / ☐ mitigated negative declaration prepared for the project is available to the general public at the office location listed above for the Lead Agency. CDFW's record of project approval as Responsible Agency is available at CDFW's regional office.

Signature Randi Adair *Date: September 13, 2016*

Stockton, CA 95203

Dear Mr. Neudeck:

Conditioned Extension of Lake or Streambed Alteration Agreement, Notification No. 1600-2014-0424-R3, San Joaquin River; RD 17 Phase 3 Levee Seepage Area Project

The California Department of Fish and Wildlife (CDFW) received your request to extend Streambed Alteration Agreement 1600-2014-0424-R3 (Agreement) and extension fee, for the above referenced agreement.

CDFW hereby agrees to extend the Agreement expiration from December 31, 2019, to December 31, 2024, with addition of the following conditions:

2.9 Riparian Brush Rabbit Avoidance. To avoid impacts to Riparian brush rabbit (RBR) from project activities, the Permittee shall implement the following measures:

2.9.1 At least 15 days prior to the Initiation of Work the Permittee shall submit to CDFW for written approval plans for an exclusion fencing system that shall be installed along the waterside boundary of the project site(s) and potential RBR habitat, and access routes as appropriate. The plan shall include a map indicating location of exclusion fencing in relation to the project site(s), location of special-status wildlife habitat features, dimension specifications, and a description of fencing materials. In addition, the following criteria for the exclusion fencing system shall be met:

- The exclusion fencing shall consist of material appropriate for exclusion of special-status species that have the potential to occur on-site (excluding avian species).
- The exclusion fencing shall either measure at least 36 inches tall above the ground or be of an appropriate height for exclusion of special-status species that have the potential to occur on-site (excluding avian species).
- The bottom of the exclusion fencing shall be buried, staked, or weighed down so as to not allow wildlife to pass through gaps or holes.
- The exclusion fencing shall be taut between the supporting stakes and shall have the supporting stakes oriented on the inside edge of the project site(s).
- The exclusion fencing shall feature one-way escape doors or an appropriate design for preventing special-status species and other wildlife from being trapped within the project site(s).
- Fencing system entry/exit points for vehicular and pedestrian traffic shall be constructed so wildlife cannot access the project site(s) during non-work hours.

- The Designated Biologist shall inspect the project site(s) prior to installation of the exclusion fencing. The exclusion fencing system shall remain in place until all construction activities have been completed. All components of the exclusion fencing will be removed for storage or disposal off-site immediately upon completion of construction activities. All vegetation slated for removal in the exclusion fencing buffer area shall be inspected by the Designated Biologist prior to the initiation of removal. Exclusion fencing shall be inspected daily by the Designated Biologist or other CDFW-approved biologist and repaired as necessary.

2.9.2 Permittee shall terminate all project activities at 1 (one) hour before sunset and shall not resume until 1 (one) hour after sunrise unless otherwise approved in writing by CDFW. Permittee shall use sunrise and sunset times established by the U.S. Naval Observatory Astronomical Applications Department for the geographic area (https://www.esrl.noaa.gov/gmd/grad/solcalc/sunrise.html).

2.9.3 Prior to the initiation of project activities, the Designated Biologist shall survey for terrestrial wildlife species. Surveys shall entail walking the entire boundary of the exclusion fence and motorized vehicle pathways as well as walking linear transects inside the fenced areas. Transects shall be spaced approximately 30 feet or less apart. Once initial grading has been completed or the exclusion fencing system has been installed then a CDFW-approved biologist may conduct the daily clearance surveys. If wildlife is found within the project site(s) the Designated Biologist or CDFW-approved biologist shall halt work and, if needed, assist the wildlife in vacating the project site(s). If special-status species are discovered within the project site(s) or directly outside the exclusion fencing, findings shall be reported to CDFW no later than four (4) hours from the time the species are observed and work within that vicinity shall be placed on hold until consultation with CDFW has been initiated. CDFW reserves the right to provide additional measures to this Agreement in the event special-status species are discovered.

2.9.4 If a rabbit species of any kind is observed within the project site(s), then all project activities shall halt, and work shall not continue until the rabbit species is identified by the Designated Biologist. If RBR is discovered at any time within the project site(s), then all project activities shall halt and CDFW shall be notified immediately, and work shall not resume until Permittee can demonstrate compliance with CESA to CDFW's satisfaction. CDFW reserves the right to provide additional RBR protection measures to this Agreement. If take of RBR is expected to occur as a result of project activities, then an Incidental Take permit is recommended.

4. Compensatory Measures

To compensate for adverse impacts to fish and wildlife resources identified above that cannot be avoided, Permittee shall implement each measure listed below.

4.1 Habitat Impacts and Mitigation. To compensate for project-related impacts to 3.31 acres of riparian habitat, Permittee shall create and restore a minimum of 9.9 acres of riparian habitat. At least 3.31 acres of the created or restored habitat shall be on site and designed to facilitate use as an RBR movement corridor.

4.2 Riparian Restoration Plan. To ensure a successful habitat creation and or restoration effort, planting shall be conducted as specified in a CDFW-approved Riparian Restoration Plan (Plan) that incorporates the Mitigation and Monitoring Plan for Levee Setback Area dated June 2016 in Appendix E of the Project's Final Biological Assessment. The Plan shall be submitted to CDFW for review and written approval 30 days prior to initiation of the project activities. The Plan shall include the following criteria:

- A description and amounts of plant species, planting ratios, and spacing, name(s) of supplying nurseries, a description, map, and reference pictures of restoration site. Replacement trees shall consist of 15-gallon saplings, 1-inch caliper sized nursery stock, or comparable nursery stock, and shrubs shall consist of 5-gallon sized nursery stock, or comparable nursery stock. Plants shall be native species adapted to the lighting, soil, and hydrological conditions at the restoration site. Hydroseed mixes shall comprise of native seed or sterile non-native seed mixes. Mitigation trees shall be identifiable through unique numbering on the map.
- A monitoring and maintenance plan that outlines adaptive management strategies to achieve the following success criteria:
  - All plantings and trees shall have a minimum of 80% survival at the end of five years.
  - Vegetation cover shall consist of no invasive plant species rated as "high" by the Cal-IPC at the end of five years.
  - If the survival and/or cover requirements are not meeting these goals, Permittee is responsible for replacement planting, additional watering, weeding, invasive exotic eradication, or any other practice, to achieve these requirements over subsequent years until the success criteria is reached. Replacement plants shall be monitored with the same survival and growth requirements as during the initial monitoring period.
  - Monitoring shall be conducted annually for a period of five years to determine whether the success criteria have been met. If the survival and/or cover requirements are not projected to meet these goals, based on annual monitoring, Permittee is responsible for replacement planting, additional watering, weeding, invasive exotic eradication, or any other practice(s) that would to achieve these requirements.
- An implementation schedule that outlines timing of planting, monitoring schedule, and estimated success criteria benchmarks.

4.3 Annual Monitoring and Mitigation Compliance Reports. Monitoring of the restoration plantings shall be reported annually for a period of five years to determine whether success criteria have been met. No later than February 15 of each year in which monitoring is required the Permittee shall electronically submit an annual report to CDFW that includes the following items: Agreement Number; a summarized description of monitoring efforts and whether compliance for mitigation has been met; recommendations to achieve compliance of mitigation that has not been met; and photo documentation of site conditions.

All other conditions in the Agreement remain in effect unless otherwise noted herein.

Copies of the original Agreement and this letter must be readily available at project worksites and must be presented when requested by a CDFW representative or other agency with inspection authority.

If you have any questions regarding this letter, please contact Jeanette Griffin, Environmental Scientist at (209) 234-3447 or Jeanette.Griffin@wildlife.ca.gov.

Sincerely,

Melissa Farinha

REQUEST TO EXTEND LAKE OR STREAMBED ALTERATION AGREEMENT

Complete EACH field, unless otherwise indicated, and submit ALL required enclosures, attachments, and fee to the CDFW regional or field office that serves the area where the project will occur. Attach additional pages to notification, if necessary.

1. APPLICANT REQUESTING EXTENSION

If the applicant is a business, agency, or utility, please include the name of the applicant's representative, who should be an employee of the applicant.

Name	Christopher Neudeck
Business/Agency	Reclamation District 17 c/o KSN
Mailing Address	711 North Pershing Avenue
City, State, Zip	Stockton, CA 95203
Phone Number	(209) 946-0268
Email	cneudeck@ksninc.com

Fish & Wildlife
APR 17 2019

2. CONTACT PERSON (*Complete only if different from applicant.*)

Name	Nicholas Tomera
Business/Agency	GEI Consultants, Inc.
Mailing Address	2868 Prospect Park Drive, Suite 400
City, State, Zip	Rancho Cordova, CA 95670
Phone Number	(916) 214-1308
Email	ntomera@gmail.com

While an applicant is legally responsible for complying with Fish and Game Code section 1602 et seq., an applicant may designate and authorize an agent (e.g., lawyer, consultant, or other individual) to act as a Designated Representative. The Designated Representative is authorized to sign the notification and any agreement on behalf of the Applicant.

Do you authorize the Contact Person above to represent you as your Authorized Designated Representative?

☑ Yes, I authorize. ☐ No, I do not authorize.

3. EXTENSION FEE

Refer to the current fee schedule to determine the appropriate fee.

☑ Extension Fee Included

Note: CDFW is not required to determine whether an extension is complete or otherwise process the extension until CDFW has received the correct fee.

4. PROJECT INFORMATION

Project Name (as identified in the Final Agreement)	RD 17 Phase 3 Levee Seepage Area Project
Agreement Number	1600-2014-0424-R3
Original Expiration Date	December 31, 2019
New Expiration Date Requested	December 31, 2024

A. Describe the following:
- The work that has been completed;
- The work that needs to be completed; and
- The amount of time needed to complete the work.

RD 17 began work in May 2014 under an emergency response action. The work was primarily limited to construction of seepage berms at Elements Ia, Ib, Ie, IIIb, IVa, Va-VIa.1, IVcde, and VIIb. RD 17 would install chimney drains, cutoff walls, and setback levee at Element IVc. See Table 2 in the Biological Assessment (GEI 2019) for work that has been completed and work that needs to be completed. RD 17 needs approximately 42 months to complete the work (which includes construction only).

☑ Continued on additional page(s)

B. Explain the reason(s) for the extension request

RD 17 could not begin work until authorized by the U.S. Army Corps of Engineers under Section 404 of the Clean Water Act and Section 14 of the Rivers and Harbors Act (i.e., 33 USC 408). Section 404 would be authorized under RGP 8 (May 2014) and NWP 13 (anticipated to be spring 2019). Section 408 would be authorized under a Categorical Permission (anticipated to be spring 2019) and Individual Permission (anticipated to be Spring 2020).

☐ Continued on additional page(s)

5. SIGNATURE

I hereby certify that to the best of my knowledge the information in this extension request ("request") is true and correct and that I am authorized to sign this request as, or on behalf of, the applicant. I understand that if any information in this request is found to be untrue or incorrect, CDFW may suspend processing this request or suspend or revoke any draft or final Lake or Streambed Alteration Agreement issued pursuant to this request. I understand also that if any information in this request is found to be untrue or incorrect, I and/or the applicant may be subject to civil or criminal prosecution.

Christopher H. Neudeck
Signature of Applicant or Applicant's Authorized Representative

Memorandum

To	Doug Weinrich – USFWS Howard Brown – NMFS	Page	1
CC	Sarah Ross, Claire Marie Turner, Krystel Bell – USACE Sean Bechta, Lisa Mangione – AECOM		
Subject	Request for Technical Assistance: Reclamation District 17 100-Year Levee Seepage Area Project		
From	Kelly Fitzgerald-Holland – AECOM		
Date	May 14, 2010		

This memorandum is a request for technical assistance with Phase 3 of Reclamation District No. 17's (RD 17's) 100-Year Levee Seepage Area Project (LSAP) (proposed project, LSAP Phase 3). This project involves flood risk reduction along approximately 8.4 miles of the approximately 19-mile RD 17 levee system. Many of the proposed project activities would occur along the San Joaquin River east levee. The overall project purpose is to implement improvements to the RD 17 levee system to meet applicable Federal and State design recommendations for levees protecting urban areas. Additional project objectives, in support of the overall project purpose, are to: (1) construct levee improvements where needed to increase the levee's resistance to underseepage and through-seepage; (2) provide seepage exit gradients of less than 0.5 at the water surface elevation associated with the 100-year flood event; and (3) implement the U.S. Army Corps of Engineers (USACE) levee vegetation management recommendations.

As stated above, one of the project objectives is to implement USACE levee vegetation management recommendations; these recommendations only pertain to levees in the federal flood control system. Approximately 2.6 miles of the 8.4-mile project area is dryland levee and, therefore, is not part of the federal flood control system and would not be subject to the USACE levee vegetation management recommendations. Implementing the USACE levee vegetation management recommendations along approximately 5.8 miles of the San Joaquin River east levee would involve removing woody vegetation on the landside levee slopes and within 15 feet of the waterside toes of levees. At this point, it is unknown whether USACE would grant a variance to the removal of vegetation along the project area. Therefore, RD 17 is requesting technical assistance in evaluating the potential Endangered Species Act (ESA) implications of adhering to USACE vegetation management standards for levees along roughly 5.8 miles of the overall project area.

Federally-listed species that could be affected by vegetation removal include: valley elderberry longhorn beetle *(Desmocerus californicus dimorphus),* riparian brush rabbit *(Sylvilagus bachmani riparius),* and the following special-status fish: Delta smelt *(Hypomesus transpacificus)*, Central Valley steelhead Distinct Population Segment (DPS) (*Oncorhynchus mykiss*), Southern DPS of North American green sturgeon (*Acipenser medirostris*), and Essential Fish Habitat (EFH) for Central Valley fall-/late fall-run Chinook salmon Evolutionarily Significant Unit (ESU) *(Oncorhynchus tshawytscha).* The potential effects of the proposed project on these species are as follows:

- **Valley elderberry longhorn beetle:** Although protocol level surveys for elderberry shrubs (the obligate host plant for valley elderberry longhorn beetle) have not yet been conducted, isolated shrubs and clumps of shrubs have been mapped during various natural resources surveys conducted by AECOM biologists in 2008 and 2010. Shrubs have been found along both sides of the San Joaquin River east levee. Approximately 16 individual shrubs and shrub clusters, which are within the project area, could be removed to comply with the USACE vegetation management standards.

- **Riparian brush rabbit:** Patches of riparian forest and scrub habitat with dense vegetation along the San Joaquin River and adjacent levee provide suitable habitat for riparian brush rabbit. This species is also known to seasonally use tall weedy/ruderal habitats that are adjacent to woody cover. Riparian brush rabbits are known to occur in the project vicinity. Small patches of potential riparian brush rabbit habitat, which occur on the water side of the levee, would be removed to comply with the USACE vegetation management standards. Portions of potential landside habitat might also be removed. While the total amount has not been quantified, the partial or total removal of isolated pockets of potential habitat could occur along up to 5.8 miles of the project area.

- **Special-status fish:** Compliance with the USACE vegetation management standards would require the removal of vegetation along the waterside levee and would result in the loss of shaded riverine aquatic (SRA) habitat. While the total amount has not been quantified, the removal of potential SRA habitat could occur along up to 5.8 miles of the project area.

USACE Planning Division will initiate ESA consultation in association with 408 authorization for the proposed project. USACE and RD 17 propose to use the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) for mitigation of project impacts on covered species, such as valley elderberry longhorn beetle. Therefore, USACE would need to be extended take coverage under the SJMSCP through an addendum of its biological opinion to the SJMSCP's biological opinion. As the SJMSCP does not cover special-status fish or the conversion of occupied riparian brush rabbit habitat, these species would need to be addressed through the ESA consultation.

USACE and RD 17 are requesting technical assistance with evaluating the potential impacts to riparian brush rabbit and special-status fish should vegetation be removed along 5.8 miles of San Joaquin River east levee (i.e., in the event that a variance to the USACE vegetation management standards is not granted). Specifically, the project proponent is requesting technical assistance in developing a compensation strategy that could adequately offset the potential loss of habitat for riparian brush rabbit and special-status fish species along 5.8 miles of the San Joaquin River east levee. To aid in your evaluation, we have attached the wetland delineation and updated maps for the proposed project area. The delineation was verified by USACE on April 9, 2010.

INTRODUCTION

Reclamation District No. 17 (RD 17) is responsible for levee operation and maintenance along the east side of the San Joaquin River in an area ranging from the City of Stockton south to the City of Manteca (Exhibit 1). RD 17 is currently undertaking a program of levee improvements at various locations to increase the levee system's resistance to underseepage. In some locations, a single form of levee improvement is proposed, such as slurry cutoff walls installed through the levee crown. In other locations, two or more improvement options are being considered, such as seepage berms and setback levees. The survey area used for this delineation encompasses the ground disturbance area required for all levee improvement options being considered at this time.

The northernmost extent of the survey area is located just south of the City of Stockton and the southernmost extent of the survey area is located in an area adjacent to the southwest edge of the Manteca city limit (Exhibit 1). The survey area ranges from approximately 5 to 25 feet above mean sea level (msl) and is located on the U.S. Geological Survey (USGS) 7.5-minute Stockton West and Lathrop Quadrangles, Townships 1 North, 1 and 2 South, Range 6 East (Exhibit 2). The nearest traditionally navigable water (TNW) of the United States is the San Joaquin River.

Because the existing levees are components of the Federal Flood Control project, various types of repair activities can require U.S. Army Corps of Engineers (USACE) review and approval for the protection of public facilities as required by 33 United States Code (USC) 408. It is anticipated that USACE approval will be required for some repair options being considered by RD 17 and therefore, USACE must complete an environmental analysis according to the National Environmental Policy Act (NEPA). RD 17 is the lead agency for implementing requirements of the California Environmental Quality Act (CEQA).

Site and Vicinity Map **Exhibit 2**

DELINEATION METHODS

Before conducting the field delineation survey, EDAW wetland ecologists reviewed color aerial photography (at a scale of 1 inch = 200 feet) of the survey area and the San Joaquin County soil survey (Soil Conservation Service [SCS] 1992) to determine areas of potential USACE jurisdiction. A wetland delineation was conducted in the survey area on March 19, 2008 by EDAW wetland ecologist Mark Bibbo and on September 22, 2009 by EDAW wetland ecologist Sarah A.N. Bennett. Precipitation in 2008 was above normal for the month of February and below normal for the month of March (National Oceanic and Atmospheric Administration [NOAA] 2008). The average precipitation in the Stockton region is 13.95 inches (Western Region Climate Center [WRCC] 2009). The precipitation accumulation for the 2009 year at the time of the 2009 field survey was 6.95 inches, approximately 2 inches below average (WRCC 2009, NOAA 2009). Field surveys were conducted on days with clear skies.

The USACE 1987 wetland delineation manual (Environmental Laboratory 1987) and *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (Environmental Laboratory 2006, 2008) were used to delineate wetlands that could be subject to USACE jurisdiction under Section 404 of the CWA. The 1987 manual and Arid West Regional Supplement provide technical guidelines and methods for the three-parameter approach to determining the location and boundaries of jurisdictional wetlands. This approach requires that an area must support positive indicators of hydrophytic vegetation, hydric soils, and wetland hydrology to be a wetland. Potential jurisdictional areas were identified and mapped in the field and later digitized onto the aerial photograph. Sample point locations were recorded digitally using a global positioning system (GPS) data logger (Trimble XH) and imported onto an electronic version of the aerial photograph. GPS data were recorded in World Geodetic System (WGS) 84 datum.

To determine whether hydrophytic vegetation dominated the area, plant species at sample sites were listed on data forms and the wetland indicator status was recorded for the dominant species using the U.S. Fish and Wildlife Service *National List of Plants that Occur in Wetlands: California (Region 0)* (Reed 1988). Hydrophytic species include those listed as obligate (OBL), facultative wetland (FACW, FACW*), or facultative (FAC, FAC*, FAC^{+}, but not FAC^{-}). The designation of a species corresponds to the probability that a species will occur in a wetland habitat. The indicator categories are defined as:

- OBL: greater than 99% occurrence in wetlands,
- FACW: between 66% and 99% occurrence in wetlands, and
- FAC: between 34% and 66% occurrence in wetlands.

The Arid West Supplement gives equal weight to all FAC-listed species (i.e., plus [$^{+}$] and minus [$^{-}$] modifiers are not used)—FAC^{-}, FAC, and FAC^{+}—plants are all considered to be FAC. A sample site was considered to have hydrophytic vegetation if greater than 50% of the dominant species had an indicator status of FAC or wetter.

Species that usually occur in nonwetlands (67–99% estimated probability), but are occasionally found in wetlands (1–33% estimated probability), are identified as facultative upland (FACU). Obligate upland (UPL) species may occur in wetlands in another region, but almost always (>99%) occur–under natural conditions–in nonwetlands in California (Region 0). A no indicator (NI) is recorded for those species for which insufficient information was available to determine an indicator status. A not listed designation (NL) indicates a species is not listed in Reed (1988). These four indicators—UPL, FACU, NI, and NL—are used to identify species not considered hydrophytic. According to standard protocol, a species with an NL designation is considered UPL when completing the "Prevalence Index Worksheet" portion of the wetland determination data form (Environmental Laboratory 2006, 2008). Botanical nomenclature follows *The Jepson Manual: Higher Plants of California* (Hickman 1993).

Wetland hydrology was assessed by recording observations such as drainage patterns, watermarks, flooded or saturated soil conditions, and other indicators of wetland hydrology. In addition, potentially jurisdictional areas were all evaluated in terms of the feature's status as a navigable waterway, adjacency, or hydrological connection to a navigable waterway.

Waters of the United States were delineated based on the ordinary high water mark (OHWM). OHWMs for drainages typically correspond with characteristics such as shelving, scour lines, and other natural linear features which define the bed and bank portion of the channel that floods under normal conditions (USACE 2005).

Soils were examined by digging soil test pits to determine whether hydric soils exist in a sampling location. Soils were described in terms of depth, matrix color, redoxymorphic color (when present), and moisture status at each sampling location. Other diagnostic features indicative of hydric soils, such as the presence of concretions and oxidized rhizospheres (a redoximorphic feature, according to Vepraskas [1992]), were also recorded on data forms. Hydric soil determinations were based on the indicators provided by the 1987 wetland delineation manual, 2008 Arid West Supplement, the *Field Indicators of Hydric Soils in the United States: A Guide for Identifying and Delineating Hydric Soils* (NRCS 2006), and Vepraskas (1992). Soil units mapped to the study area by the soil survey were cross-referenced to *The National Hydric Soils List by State (California)* to determine if the soil was listed as a hydric map unit (NRCS 2008).

The *U.S Army Corps of Engineers Jurisdictional Determination Form Instructional Guidebook* was consulted to aid the preliminary determination that an area would be subject to USACE jurisdiction under Section 404 of the CWA (USACE 2007). The significant nexus test—outlined in a memorandum jointly authored by the U.S. Environmental Protection Agency (EPA) and USACE—was applied to each potentially jurisdictional habitat type (Grumbles and Woodley 2007, 2008). Features within the survey area that are potentially subject to USACE jurisdiction under Section 404 of the CWA are ditches and wetlands adjacent to the San Joaquin River, a TNW. Fifteen data forms were completed within the survey area; data forms are provided in Appendix A.

SOIL SURVEY RESULTS

According to the Soil Survey of San Joaquin County (SCS 1992) the soils within the survey area belong to the Columbia, Dello, Egbert, Meritt, Valdez, and Grangeville soil series. Descriptions of soil map units that occur within the survey area are provided below. A soils map showing the survey area is included in Appendix B.

All soils within the survey area are listed as hydric on the National Hydric Soils List (National Resources Conservation Service [NRCS] 2008). Soils within the survey area have been modified extensively by levees, thereby making the soils within the survey area subject to “atypical situation” as described in the 1987 wetland delineation manual (Environmental Laboratory 1987). The soils within the survey area formed under conditions that were subject to regular flood events, as is supported by the mapped unit soil series descriptions. However, the current hydrology of the survey area is not the condition under which soil formation took place; the natural hydrology of this area has been altered by the presence of flood control structures. Therefore, careful consideration is warranted when making a hydric soil determination for the purposes of defining USACE jurisdiction of wetlands under Section 404 of the CWA.

MERRITT SILTY CLAY LOAM, PARTIALLY DRAINED, 0 TO 2 PERCENT SLOPES (MAP UNIT 197)

The Merritt series consists of very deep, poorly drained soils on floodplains. These soils are artificially drained and are very deep. They formed in alluvium derived form mixed rock sources. Slope ranges from 0 to 2 percent. Included in this unit are small areas of Egbert, Ryde, Grangeville, and Guard soils. Included areas account for approximately 15 percent of the total acreage of this map unit. Permeability is moderately slow in the Merritt soils. The soils are under intensive cultivation and are irrigated, producing a wide variety of field and row crops. Merritt soils belong to the fine-silty, mixed, superactive, thermic Fluvaquentic Haploxerolls taxonomic class.

VALDEZ SILT LOAM, ORGANIC SUBSTRATUM, PARTIALLY DRAINED, 0 TO 2 PERCENT SLOPES (MAP UNIT 261)

The Valdez series consists of very deep, poorly drained soils that formed in recent alluvial material from mixed rock sources. Valdez soils are near rivers, sloughs and old stream channels in river deltas and flood plains and have slopes of 0 to 2 percent. Included in this unit are small areas of Itano, Kingile, Peltier, Piper, Rindge, Ryde, and Shinkee soils. Included areas account for approximately 15 percent of the total acreage of this map unit. Valdez soils are poorly drained under natural conditions, with slow to very slow runoff and moderately slow permeability. The water table fluctuates from 3 feet to below 5 feet in many drained areas. Irrigated areas are used for intensive row and field crops. Valdez soils belong to the fine-silty, mixed, nonacid, thermic Aeric Fluvaquents taxonomic class.

DELLO CLAY LOAM, DRAINED, 0 TO 2 PERCENT SLOPES, OVERWASHED (MAP UNIT 148)

The Dello series consist of very deep, very poorly drained soils that formed in alluvium from granitic rock sources. Dello soils are in small depressions and have slopes of 0 to 2 percent. Included in this unit are small areas of Columbia, Egbert, Merritt, and unnamed stratified substratum. Included areas account for approximately 15 percent of the total acreage of this map unit. Dello soils are very poorly drained, with slow runoff and rapid permeability (clay substratum phase has slow permeability below a depth of 40 inches). In some areas a water table is more than 6 feet from the surface because of flood control structures and/or installed drains. Areas with these soils are primarily used for irrigated field and row crops. Dello soils belong to the mixed, thermic Typic Psammaquents taxonomic class.

EGBERT SILTY CLAY LOAM, PARTIALLY DRAINED, 0 TO 2 PERCENT SLOPES (MAP UNIT 153)

This very deep, artificially drained soil occurs on high floodplains and in backwater swamps. A system of levees and large upstream dams has reduced or virtually eliminated incidents of inundation in most areas. The water table has been lowered due to levees, open and closed drains, and pumps; the lowered water table has altered the drainage of this soil. This soil formed in somewhat poorly drained alluvium derived from mixed rock sources. Included in this unit are small areas of Grangeville, Stockton, Willows, Columbia, Merritt, and Schribner soils. Included areas account for approximately 15 percent of the total acreage of this map unit. Permeability is slow in the Egbert soil. The effective rooting depth is limited by a high seasonal water table in winter and early spring. The water table is high because of seepage and is generally maintained at a depth of 36 to 60 inches by pumping; however, the water table is subject to fluctuation throughout the year. Runoff is very slow and the hazard of water erosion is slight. This soil may provide wetland functions and values when not altered by artificial drainage and groundwater pumping as natural vegetation found in areas of this mapped unit are generally composed of hydrophytic plants, sedges, annual grasses, and forbs. Egbert soils belong to the fine, mixed, non-acid, thermic Cumlic Haplaquolls taxonomic class.

COLUMBIA FINE SANDY LOAM, DRAINED, 0 TO 2 PERCENT SLOPES (MAP UNIT 130)

This very deep, artificially drained soil occurs on natural levees on low floodplains along rivers and sloughs. The water table has been lowered due to levees, open and closed drains, and pumps. The lowered water table has altered the drainage of this soil. This soil formed in somewhat poorly drained alluvium derived from mixed rock sources. A system of levees and large upstream dams has or virtually eliminated incidents of inundation in most areas. Included in this unit are small areas of Columbia soils that have a clayey substratum and inclusions of Sailboat and Valpac soils. Included areas account for 15 percent of the total acreage of this map unit. Permeability is moderately rapid in the Columbia soil. The effective rooting depth is limited by a high seasonal water table. The water table is high because of seepage and is generally maintained below a depth of 36 inches by pumping; the water table can be found at a depth of 20–36 inches for short periods. Runoff is very slow or slow and the hazard of water erosion is slight to non-existent. This soil is subject only to rare periods of flooding. This soil may provide wetland functions and values when not altered by artificial drainage and groundwater pumping. Columbia soils belong to the course-loamy mixed, non-acid, thermic Aquic Xerofluvents taxonomic class.

GRANGEVILLE FINE SANDY LOAM, PARTIALLY DRAINED, 0 TO 2 PERCENT SLOPES (MAP UNIT 166)

The Grangeville series consists of very deep, somewhat poorly drained soils that formed in moderate coarse textured alluvium dominantly from granitic rock sources. Grangeville soils are on alluvial fans and floodplains and have slopes ranging from 0 to 2 percent. Some areas are saline and saline-sodic affected. Included in this unit are small areas of Columbia, Dello, Egbert, Merrit and Valdez soil series. Included areas account for 85% of this map unit. Grangeville soils are somewhat poorly drained. This soil has altered drainage because of the dams and reservoirs in the Sierra Nevada, pumping from the water table, tile and interceptor drains, and filling and leveling of sloughs in the vicinity. This soil has negligible to very low runoff; moderately rapid permeability and moderate permeability in saline-sodic phases. Formerly most areas of Grangeville soils were occasionally flooded, but now stream flow is controlled by large flood control structures to the extent that most areas are not flooded more than once in about 25 to 75 years. The water table is at depths of 24 to 48 inches unless drained. If drained, the water table is at depths of 48 to greater than 60 inches.

GALT CLAY, 0-2% SLOPES (MAP UNIT 160)

This moderately deep, moderately well drained soil occurs on basin rims and low terraces. This soil formed in fine textured alluvium derived from mixed rock sources. Included in this unit are small areas of Archerdale, Vignolo, Hollenbeck, and Stockton soils. Included areas account for approximately 15 percent of the total acreage of this map unit. Permeability is slow in the Galt soil. The effective rooting depth is limited by the depth of the hardpan, which is generally located 20 to 40 inches below the soil surface. Runoff is very slow and the hazard of water erosion is slight. The shrink-swell capacity of this soil is high. This soil may provide wetland functions and values when not altered by artificial drainage. Galt soils belong to the fine, montmorillonitic, thermic Typic Chromoxerents taxonomic class.

A typical soil profile has a grayish brown clay surface layer approximately 25 inches thick. The underlying material is brown clay about 9 inches thick. A weakly cemented hardpan is found at a depth of range of 20 to 40 inches below the soil surface.

DELINEATION RESULTS

Approximately 4.847 acres of potentially jurisdictional waters of the United States are present within the 231.948-acre survey area (Table 1). Potentially jurisdictional features within the survey area include 2.254 acres of drainage ditch, 0.024 acre of freshwater marsh, and 2.569 acres of open water pond. These features meet the three-parameter wetland definition outlined by the wetland delineation manual and Arid West Regional Supplement and/or have an OHWM that meets the definition of waters of the United States. Because these features are adjacent to the San Joaquin River, a TNW, these areas would be considered wetlands adjacent to waters of the United States (Grumbles and Woodley 2007, 2008). Sites qualifying as waters of the United States according to Section 404 of the CWA are depicted on the set of maps in Exhibits 3a to 3i. Delineation sample sites are also included in these exhibits and are cross-referenced to the wetland determination data forms provided in Appendix A. Habitat descriptions for jurisdictional and nonjurisdictional habitats are included below; a habitat map is provided in Appendix C. Representative photographs of habitat types are provided in Appendix D, and a list of species observed within the survey area is provided as Appendix E.

DRAINAGE DITCHES

Eight drainage ditches were mapped within the survey area. These ditches primarily function as drainage ditches for the adjacent agricultural fields. Three of the ditches (DD2, DD3, and DD4) exhibited indicators of hydric vegetation, hydric soils and hydrology (Exhibits 3b and 3c). A fourth drainage ditch, DD1, lacked indicators of hydric vegetation, hydric soils and hydrology (Exhibit 3a). This feature is discussed further in the section describing nonjurisdictional features. In ditches DD2, DD3, and DD4, the vegetation was dominated by plant species indicative of seasonal wetlands. Species observed included a mix of obligate and facultative species such as umbrella sedge (*Cyperus eragrostis*)(FACW), rabbitsfoot grass (*Polypogon monspeliensis*)(FACW), water primrose (*Ludwigia peploides* ssp. *peploides*) (OBL), curlytop knotweed (*Polygonum lapathifolium)*(FACW), prickly lettuce (*Lactuca serriola*) (FAC), and curly dock (*Rumex crispus*) (FACW). In addition, drainage ditches in reaches 4 and 5 (DD3 and DD4) had occasional cover of arroyo willow (*Salix lasiolepis*)(FACW) and sandbar willow (*Salix exigua*) (OBL).

Hydric soil indicators observed in drainage ditches included a sandy gleyed matrix in DD2, and redoximorphic features in a sandy soil in DD3 and DD4. In DD2, soil saturation was observed in the top 14 inches and water stained leaves served as indicators of hydrology. Soil surface cracks served as indicators of hydrology in DD3 and DD4.

An OHWM was observed and measured for DD2–D8. DD2–DD4 had an OHWM of approximately 2 feet wide. DD5 and DD7 are larger irrigation/drainage ditches; these features had an OHWM of approximately15 feet. DD6 and DD8 have an OHWM of approximately 10 feet. The boundaries of the OHWM was based on observed physical characteristics of the feature such as the presence of a bed and bank, a change in plant community, and a natural line impressed on the bank (USACE 2005). For the purposes of Section 404 of the Clean Water Act, the lateral limits of jurisdiction over non-tidal water bodes extends to the OHWM in the absence of adjacent wetlands (Grumble and Woodley 2007, 2008).

The drainage ditches are supplied with water from the San Joaquin River via runoff from irrigation of the adjacent agricultural fields. Due to their proximity to the toe of the levee and the San Joaquin River, these wetland features may be connected to the San Joaquin River via sub-surface hydrology. The drainage ditches within the survey area total approximately 2.254 acres. Wetlands and water features adjacent to waters of the United States (in this case the San Joaquin River, a TNW) are considered jurisdictional under Section 404 of the CWA and the Rapanos and Carabell decisions (Grumbles and Woodley 2007, 2008).

Data forms 4, 6, 8, 10, and 15 in Appendix A provide information on the drainage ditches within the survey area. Data forms 5, 7, and 9 provide information on the surrounding upland area.

Wetland Delineation Map (9 of 9) **Exhibit 3i**

FRESHWATER MARSH

A small portion of freshwater marsh habitat, totaling 0.024 acre, is located in a depression within the survey area boundary (Exhibit 3a). Freshwater marshes are herbaceous wetlands that occur along the edges of rivers and lakes and are dominated by emergent vegetation such as grasses, reeds, rushes, and sedges. Marshes are typically perennial wetlands, but may dry out for short periods of time (Cowardin 1979).

The freshwater marsh observed in the survey area is a small piece of a larger marsh (located outside the survey area) that is dominated by narrowleaf cattail (*Typha angustifolia*) (OBL) and common tule (*Scirpus acutus*) (OBL). A few riparian shrubs and trees, including red willow (*Salix laevigata*) (NL), arroyo willow (*Salix lucida* spp. *lasiandra*) (FACW), and box elder (*Acer negundo*) (FACW), occur on the edge of the marsh outside of the survey area boundary. This habitat is characterized by primary indicators of wetland hydrology, including the presence of inundated and saturated soils as well as sediment deposits and drainage patterns.

The freshwater marsh is hydrologically connected to the San Joaquin River via irrigation and drainage ditch pumps. In addition to receiving flow from nearby ditches, this habitat may be maintained by surface and sub-surface water flows from adjacent uplands that naturally drain into the area due to topographic gradients. The freshwater marsh meets the three-parameter wetland definition outlined by the wetland delineation manual and Arid West Regional Supplement. The freshwater marsh is adjacent to the San Joaquin River separated only by an artificial levee. Wetlands adjacent to TNWs are considered jurisdictional under Section 404 of the CWA and the Rapanos and Carabell decisions (Grumbles and Woodley 2007, 2008).

Data form 2 in Appendix A provides information on the freshwater wetland feature. Data form 3 provides information on the surrounding upland area.

POND

One artificial pond was documented in Reach IIb of the survey area. The pond is a result of anthropogenic earth moving activities and is not a natural feature on the landscape. The pond is an open water habitat surrounded by a landscaped yard and weeping willows (*Salix babylonica*) (FACW). The pond may be connected to the San Joaquin River via subsurface hydrology. The pond is likely subject to USACE jurisdiction under Section 404 of the CWA because it is a deepwater aquatic habitat adjacent to the San Joaquin River, a TNW.

POTENTIALLY NONJURISDICTIONAL HABITATS

Potentially nonjurisdictional habitats account for 227.101 acres of the study area (Table 2). The habitats described below are considered nonjurisdictional under Section 404 of the CWA because they do not meet the three parameter criteria for wetlands. The developed habitat type mapped on approximately 42.367 acres of the survey area includes land uses such as residences, landscaped grounds around residences, and other areas of non-agricultural, non-natural land use. A habitat map is included in Appendix C.

Table 2
Potentially Nonjurisdictional Habitats within the Survey Area

Habitat	Acres
Agricultural/Ruderal	184.722
Developed	42.367
Drainage Ditch (DD1)	0.012
Total Nonjurisdictional Habitats	**227.101**

Source: Data compiled by EDAW in 2009

AGRICULTURAL/RUDERAL

The majority of the survey area, approximately 184.722 acres, consists of actively farmed or fallow agricultural land, and ruderal areas on the edges of fields. Actively farmed lands include row crops, grain crops, and orchards. Fallow fields are dominated by a variety of non-native annual grasses such as wild oats (*Avena fatua*) (NL), ripgut brome (*Bromus diandrus*) (NI), and broadleaf weeds including wild radish (*Raphanus sativa*) (NL), field bindweed (*Convolvulus arvensis*) (NL), and black mustard (*Brassica nigra*) (NL).

Ruderal areas are those that have been stripped of their native vegetative cover and that are either covered by gravel or dirt or dominated by weedy non-native species. Ruderal areas are common along the landside of the San Joaquin River levee throughout the survey area, as the vegetation in this area is maintained periodically through prescribed fire and/or mowing. The levee slopes are generally dominated by non-native grasses and forbs such as wild oats, Italian ryegrass (*Lolium multiflorum*) (FAC), blessed milk thistle (*Silybum marianum*) (NL), velvet leaf (*Abutilon theophrasti*) (NI), Russian knapweed (*Acroptilon repens*) (NL), and yellow star-thistle (*Centaurea solstitialis*) (NL). Ruderal areas in the survey area are not likely to fall under USACE jurisdiction as a wetland or waters of the United States because this habitat lacks hydrophytic vegetation and hydric soils, does not have wetland hydrology, and lacks an OHWM.

Data forms 3, 5, 7, and 9 provide information on the upland agricultural and ruderal areas.

DEVELOPED

Developed areas within the study area total approximately 42.367 acres. Developed areas include paved roads, parking lots, buildings, and areas cleared of natural vegetation in preparation for development. Developed areas are not likely to fall under USACE jurisdiction as a wetland or waters of the United States because this habitat lacks hydrophytic vegetation, hydric soils, and does not have wetland hydrology; developed areas are also located outside an OHWM.

DRAINAGE DITCH, DD1

One of the drainage ditches totaling approximately 0.012 acre, DD1, in Reach Ia did not meet the three parameter wetland criteria, nor did this feature have a surface hydrological connection to other waters of the United States. DD1 also lacked indicators of an OHWM. This ditch is located along the edge of a fallow agricultural field; this feature was presumed abandoned because it lacks an OHWM. This feature is not likely subject to USACE jurisdiction under Section 404 of the CWA because it does not meet the three parameter wetland criteria as defined by the 1987 wetland delineation manual and the Arid West Regional Supplement (Environmental Laboratory 1987, 2006) nor does DD1 have an OHWM. Data form 1 provides information on this potentially nonjurisdictional abandoned drainage ditch feature.

JURISDICTIONAL DETERMINATION

The 231.948-acre survey area contains approximately 4.847 acres of waters of the United States, comprised of 0.024 acre of freshwater marsh, 2.569 acres of pond, and 2.254 acres of drainage ditches that are potentially subject to USACE jurisdiction under Section 404 of the CWA. The freshwater marsh meets the three parameter criteria of wetlands (i.e., presence of hydrophytic vegetation, hydric soils, and wetland hydrology) outlined in the 1987 wetland delineation manual and Arid West Regional Supplement (Environmental Laboratory 1987, 2006, 2008). The seven drainage ditches that have an OHWM are also potentially subject to USACE jurisdiction under Section 404 as waters of the United States. The open water pond in Reach IIb is potentially subject to USACE jurisdiction under Section 404 because this feature is likely connected via a subsurface hydrological connection to the San Joaquin River. The San Joaquin River is listed by the USACE Sacramento District office as an established navigable waterway (USACE 2008). The waters and wetlands identified as potentially jurisdictional within the survey area are therefore considered adjacent to the San Joaquin River, a TNW.

DD1 was presumed abandoned because it lacks an OHWM and is located in an agricultural field that appears to have been fallow for several growing seasons. DD1 is not likely to be subject to USACE jurisdiction under Section 404 of the CWA because this feature does not have wetland characteristics (i.e., hydrophytic vegetation, hydric soils, and wetland hydrology) and lacks an OHWM.

Wetland Delineation Data Forms

Map 1

WETLAND DETERMINATION DATA FORM – Arid West Region

Project/Site: RD 17 Levee Repair Project City/County: San Joaquin County Sampling Date: 5/19/2008

Applicant/Owner: RD 17 State: CA Sampling Point: 1

Investigator(s): M.Bibbo/ J. Downs Section, Township, Range: (DD1)

Landform (hillslope, terrace, etc.): flat river terrace Local relief (concave, convex, none): flat Slope (%): ____

Subregion (LRR): ____ Lat: ____ Long: ____ Datum: ____

Soil Map Unit Name: ____ NWI classification: ____

Are climatic / hydrologic conditions on the site typical for this time of year? Yes ____ No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? no Are "Normal Circumstances" present? Yes ✓ No ____

Are Vegetation ____, Soil ____, or Hydrology ____ naturally problematic? no (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ✓	No ____	Is the Sampled Area within a Wetland? Yes ____ No ✓
Hydric Soil Present?	Yes ____	No ✓	
Wetland Hydrology Present?	Yes ____	No ✓	

Remarks: Ag ditch on edge of fallow field.

Sampling Point: 1

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth (inches)	Matrix Color (moist)	Matrix %	Redox Features Color (moist)	Redox %	Type[1]	Loc[2]	Texture	Remarks
0-12	2.5YR 4/3	100	none				sandy loam	

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix. [2]Location: PL=Pore Lining, RC=Root Channel, M=Matrix.

Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5) **(LRR C)**
- ___ 1 cm Muck (A9) **(LRR D)**
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- ___ Loamy Mucky Mineral (F1)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- ___ Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Vernal Pools (F9)

Indicators for Problematic Hydric Soils[3]:

- ___ 1 cm Muck (A9) **(LRR C)**
- ___ 2 cm Muck (A10) **(LRR B)**
- ___ Reduced Vertic (F18)
- ___ Red Parent Material (TF2)
- ___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present.

Restrictive Layer (if present):

Type: ____________

Depth (inches): ____________

Hydric Soil Present? Yes ______ No ✓

Remarks:

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (any one indicator is sufficient)

- ___ Surface Water (A1)
- ___ High Water Table (A2)
- ___ Saturation (A3)
- ___ Water Marks (B1) **(Nonriverine)**
- ___ Sediment Deposits (B2) **(Nonriverine)**
- ___ Drift Deposits (B3) **(Nonriverine)**
- ___ Surface Soil Cracks (B6)
- ___ Inundation Visible on Aerial Imagery (B7)
- ___ Water-Stained Leaves (B9)
- ___ Salt Crust (B11)
- ___ Biotic Crust (B12)
- ___ Aquatic Invertebrates (B13)
- ___ Hydrogen Sulfide Odor (C1)
- ___ Oxidized Rhizospheres along Living Roots (C3)
- ___ Presence of Reduced Iron (C4)
- ___ Recent Iron Reduction in Plowed Soils (C6)
- ___ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

- ___ Water Marks (B1) **(Riverine)**
- ___ Sediment Deposits (B2) **(Riverine)**
- ___ Drift Deposits (B3) **(Riverine)**
- ___ Drainage Patterns (B10)
- ___ Dry-Season Water Table (C2)
- ___ Thin Muck Surface (C7)
- ___ Crayfish Burrows (C8)
- ___ Saturation Visible on Aerial Imagery (C9)
- ___ Shallow Aquitard (D3)
- ___ FAC-Neutral Test (D5)

Field Observations:

Surface Water Present? Yes ______ No ✓ Depth (inches): ______

Water Table Present? Yes ______ No ✓ Depth (inches): ______

Saturation Present? (includes capillary fringe) Yes ______ No ✓ Depth (inches): ______

Wetland Hydrology Present? Yes ______ No ✓

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks: Ditch collects runoff from adj ag field, likely doesn't flow into any other waters

Indicators of OHWM not observed.

- ___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present.

Hydrophytic Vegetation Present? Yes ____ No ✓

Remarks:

SOIL

Sampling Point: 9

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth (inches)	Matrix Color (moist)	Matrix %	Redox Features Color (moist)	Redox %	Type[1]	Loc[2]	Texture	Remarks
0-6	10YR 4/3	100		None				

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix. [2]Location: PL=Pore Lining, RC=Root Channel, M=Matrix.

Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5) (**LRR C**)
- ___ 1 cm Muck (A9) (**LRR D**)
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- ___ Loamy Mucky Mineral (F1)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- ___ Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Vernal Pools (F9)

Indicators for Problematic Hydric Soils[3]:

- ___ 1 cm Muck (A9) (**LRR C**)
- ___ 2 cm Muck (A10) (**LRR B**)
- ___ Reduced Vertic (F18)
- ___ Red Parent Material (TF2)
- ___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present.

Restrictive Layer (if present):
Type: compaction
Depth (inches): 6"

Hydric Soil Present? Yes ___ No ✓

Remarks:

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (any one indicator is sufficient)

- ___ Surface Water (A1)
- ___ High Water Table (A2)
- ___ Saturation (A3)
- ___ Water Marks (B1) (**Nonriverine**)
- ___ Sediment Deposits (B2) (**Nonriverine**)
- ___ Drift Deposits (B3) (**Nonriverine**)
- ___ Surface Soil Cracks (B6)
- ___ Inundation Visible on Aerial Imagery (B7)
- ___ Water-Stained Leaves (B9)
- ___ Salt Crust (B11)
- ___ Biotic Crust (B12)
- ___ Aquatic Invertebrates (B13)
- ___ Hydrogen Sulfide Odor (C1)
- ___ Oxidized Rhizospheres along Living Roots (C3)
- ___ Presence of Reduced Iron (C4)
- ___ Recent Iron Reduction in Plowed Soils (C6)
- ___ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

- ___ Water Marks (B1) (**Riverine**)
- ___ Sediment Deposits (B2) (**Riverine**)
- ___ Drift Deposits (B3) (**Riverine**)
- ___ Drainage Patterns (B10)
- ___ Dry-Season Water Table (C2)
- ___ Thin Muck Surface (C7)
- ___ Crayfish Burrows (C8)
- ___ Saturation Visible on Aerial Imagery (C9)
- ___ Shallow Aquitard (D3)
- ___ FAC-Neutral Test (D5)

Field Observations:

Surface Water Present? Yes ___ No ___ Depth (inches): ___
Water Table Present? Yes ___ No ___ Depth (inches): ___
Saturation Present? (includes capillary fringe) Yes ___ No ___ Depth (inches): ___

Wetland Hydrology Present? Yes ___ No ✓

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks: Upland

APPENDIX D

Representative Photographs

An agricultural field in Reach Ia depicts the dominant land use in the survey area.

Freshwater marsh habitat on the land side of the levee in Reach Ib is dominated by narrow-leaved cattail.

The drainage ditch in Reach IVa (DD2) was dry at the time of the field survey but had saturated soils indicating recent saturation and was dominated by obligate wetland plant species such as floating water primrose.

Riparian shrubs such as arroyo willow and young Fremont's cottonwood trees are present in DD3 in IVc.

APPENDIX E

Plant Species Observed

Common Name	Scientific Name	Wetland Status
Velvetleaf	*Abutilon theophrasti*	NI
Box elder	*Acer negundo*	FACW
Russian knapweed	*Acroptilon repens*	NL
Silver hairgrass	*Aira caryophyllea*	NL
Scarlet pimpernel	*Anagallis arvensis*	FAC
Sweet vernal grass	*Anthoxanthum odoratum*	FACU
Giant reed	*Arundo donax*	FACW
Slender oat	*Avena barbata*	NL
Wild oat	*Avena fatua*	NL
Coyote bush	*Baccharis pilularis*	NL
Black mustard	*Brassica nigra*	NL
Ripgut brome	*Bromus diandrus*	NL
Soft chess	*Bromus hordeaceus*	NL
Italian thistle	*Centaurea repens*	NL
Yellow star-thistle	*Centaurea solstitialis*	NL
Chicory	*Cichorium intybus*	NL
Field bindweed	*Convolvulus arvensis*	NL
Canadian horseweed	*Conyza canadensis*	FAC
Pricklegrass	*Crypsis vaginiflora*	OBL
Bermuda grass	*Cynodon dactylon*	FAC
Umbrella sedge	*Cyperus eragrostis*	FACW
Orchard grass	*Dactylis glomerata*	FACU
Jimson weed	*Datura stramonium*	NL
Barnyard grass	*Echinochloa crus-galli*	FACW
Broadleaf filaree	*Erodium botrys*	NL
Annual fireweed	*Epilobium brachycarpum*	NL
Slender willow-herb	*Epilobium ciliatum*	FACW
Bedstraw	*Galium aparine*	FACU
Cut-leaf geranium	*Geranium dissectum*	NL
Cudweed everlasting	*Gnaphalium luteo-album*	FACW
Great Valley gumweed	*Grindelia camporum*	FACU
Telegraph weed	*Heterotheca grandiflora*	NL
Mediterranean barley	*Hordeum marinum*	FAC
Foxtail barley	*Hordeum murinum*	NL
California black walnut	*Juglans californica*	FAC
Toad rush	*Juncus bufonius*	FACW

Note:
FAC = facultative
FACU = facultative upland
FACW = facultative wetland
NI = no indicator
NL = not listed
OBL = obligate
UPL = upland

Common Name	Scientific Name	Wetland Status
Common rush	*Juncus effusus*	OBL
Prickly lettuce	*Lactuca serriola*	FAC
Duckweed	*Lemna minor*	OBL
Perennial pepperweed	*Lepidium latifolium*	FACW
Italian ryegrass	*Lolium multiflorum*	FAC
Japanese honeysuckle	*Lonicera japonica*	NI
Birds-foot trefoil	*Lotus corniculatus*	FAC
Water primrose	*Ludwigia peploides* ssp. *peploides*	OBL
Hyssop loosestrife	*Lythrum hyssopifolia*	FACW
Cheeseweed	*Malva parviflora*	NL
Bur-clover	*Medicago polymorpha*	NL
Alfalfa	*Medicago sativa*	NL
Indian sweetclover	*Melilotus indica*	FAC
Tree tobacco	*Nicotiana glauca*	FAC
Common evening primrose	*Oenothera biennis*	NL
Dallisgrass	*Paspalum dilatatum*	FAC
English plantain	*Plantago lanceolata*	FAC
Annual blue grass	*Poa annua*	FACW
Common knotweed	*Polygonum arenastrum*	NL
Curlytop knotweed	*Polygonum lapathifolium*	FACW
Rabbitsfoot grass	*Polypogon monspeliensis*	FACW
Fremont's cottonwood	*Populus fremontii*	FACW
Valley oak	*Quercus lobata*	FAC
Wild radish	*Raphanus sativa*	NL
Himalayan blackberry	*Rubus discolor*	FACW
Curly dock	*Rumex crispus*	FACW
Weeping willow	*Salix babylonica*	FACW
Sandbar willow	*Salix exigua*	OBL
Gooding's willow	*Salix gooddingii*	OBL
Red willow	*Salix laevigata*	NL
Arroyo willow	*Salix lasiolepis*	OBL
Blue elderberry	*Sambucus mexicana*	FAC
Blessed milk thistle	*Silybum marianum*	NL
Russian tumbleweed	*Salsola tragus*	NL
Sow thistle	*Sonchus oleraceus*	NL
Johnsongrass	*Sorghum halepense*	FACU

Note:

FAC = facultative
FACU = facultative upland
FACW = facultative wetland
NI = no indicator
NL = not listed
OBL = obligate
UPL = upland

Common Name	Scientific Name	Wetland Status
Field hedge parsley	*Torilis arvensis*	NL
Poison oak	*Toxicodendron diversilobum*	NL
Red clover	*Trifolium hirtum*	NL
Broad-leaf cattail	*Typha latifolia*	OBL
Narrow-leaf cattail	*Typha angustifolia*	OBL
Stinging nettle	*Urtica dioica*	FACW
South American vervain	*Verbena bonariensis*	FACW
Common vetch	*Vicia sativa*	NL
Wild grape	*Vitis californica*	FACW
Foxtail fescue	*Vulpia myuros*	FACU
Cocklebur	*Xanthium strumarium*	FAC

Note:
FAC = facultative
FACU = facultative upland
FACW = facultative wetland
NI = no indicator

2. Letter from NMFS to AECOM, Responding to Technical Assistance Request. June 11, 2010.

UNITED STATES DEPARTMENT OF COMMERCE
National Oceanic and Atmospheric Administration
NATIONAL MARINE FISHERIES SERVICE
Sacramento Area Office
650 Capitol Mall, Suite 8-300
Sacramento, California 95814-4706

JUN 11 2010

Kelly Fitzgerald-Holland
AECOM
2020 L Street, Suite 400
Sacramento, California 95811

Dear Ms. Fitzgerald-Holland:

This is in response to your May 14, 2010, letter requesting technical assistance from NOAA's National Marine Fisheries Service (NMFS) for the Preliminary Delineation of Waters of the United States, Including Wetlands for the Reclamation District (RD) 100-Year Levee Seepage project. The survey for the Preliminary Delineation ranges from the northernmost extent located just south of the City of Stockton to the southernmost extent located adjacent to the southwest edge of the Manteca city limit. The survey area is located on the U.S. Geological Survey 7.5-minute Stockton West and Lathrop Quadrangles, Townships 1 North, 1 and 2 South, Range 6 East.

The existing levees associated with this project are a part of the Federal Flood Control project. Some of the RD 17 100-year Levee Seepage Area project repair activities will require U.S. Army Corps of Engineers (USACE) review and approval for the protection of public facilities as required by 33 United State Code 408. Thus, USACE must complete National Environmental Policy Act (NEPA) environmental analysis. RD 17 will be the lead agency for completing requirements of the California Environmental Quality Act (CEQA).

NMFS has reviewed the information provided with your May 14, 2010, letter. NMFS as an agency has no authority over the methods or conclusions related to a Wetland Delineation. However, we appreciate the early involvement in the RD 17 100-Year Levee Seepage project because the eventual NEPA and CEQA analysis will involve Endangered Species Act (ESA) issues relevant to NMFS.

As the project progresses, it is anticipated that the project applicants will seek out formal comments or consultation as required under the ESA of 1973, as amended (16 U.S.C. 1531 et seq.). Be advised that NMFS can only enter formal section 7 consultation with another federal agency or its designee. Future section 7 consultation for the RD 100-Year Levee Seepage project will involve possible effects of the proposed project on the federally listed threatened Central Valley (CV) steelhead (*Oncorhynchus mykiss*) and Southern distinct population segment (DPS) of North American green sturgeon (*Acipenser Medirostris*). The project is also within the boundaries of designated CV steelhead (*O. mykiss*) and Southern DPS of North American green sturgeon (*A. Medirostris*) critical habitat.

We recommend that for future ESA and Magnuson-Stevens Fishery Conservation and Management Act consultations, the applicants analyze permitted activities to evaluate the direct, indirect, interrelated, interdependent, and cumulative effects related to Federally protected anadromous fish species and their habitat.

If you have any questions regarding this correspondence contact Mike Hendrick, Fisheries Biologist, by telephone at (916) 930-3605 or by e-mail at Michael.Hendrick@noaa.gov.

Sincerely,

For

Maria Rea
Central Valley Office Supervisor

3. Letter from USACE to USFWS, requesting initiation of formal consultation. March 27, 2015. Includes one attachment (February 2015 Biological Assessment).

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS, SACRAMENTO DISTRICT
1325 J STREET
SACRAMENTO, CALIFORNIA 95814-2922

Environmental Resources Branch

Ms. Maria Rae, Assistant Regional Administrator
National Marine Fisheries Service
650 Capitol Mall, Suite 5-100
Sacramento, California 95814-4700

Dear Ms. Rae:

I am writing to continue informal consultation under Section 7 of the Endangered Species Act, for a combined Department of Army permit application and a Section 408 permission request for Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair Project. We are also requesting to consult with your agency under the Magnusson-Stevens Fishery Conservation and Management Act (MSA) for Pacific Coast Salmon (*Oncorhynchus* spp.) essential fish habitat (EFH). The project is proposed by RD 17, and is located along the San Joaquin River in RD 17 in San Joaquin County, California. A copy of the February 2017, "Phase 3 – RD 17 Levee Seepage Repair Project, Final Biological Assessment" (BA), prepared by GEI, is enclosed.

The Sacramento District (Corps) originally requested to informally consult in a letter dated March, 27, 2015. The National Marine Fisheries Service (NMFS) responded in a letter, dated July 7, 2015, and requested additional information (Appendix D-3). Our specific responses to each element of the information request are provided in Appendix D-4 of the enclosed biological assessment (BA). This information has also been incorporated into the main body of the BA, as appropriate. The BA also includes an updated description of the proposed action.

Based on the available information, we have determined that the action may affect, but is not likely to adversely affect, Federally listed Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*), Central Valley spring-run Chinook salmon ESU (*Oncorhynchus tshawytscha*), Sacramento River winter-run Chinook salmon ESU (*Oncorhynchus tshawytscha*) and the Southern DPS of North American green sturgeon (*Acipenser medirostris*). The proposed action will not result in destruction or adverse modification of designated critical habitat for any of these species and will not adversely affect designated Chinook salmon EFH. We request your written concurrence with our determinations. If new information becomes available indicating that other listed species or critical habitat may be affected, we will follow the procedures under 50 CFR 402.16, Reinitiation of Consultation.

The RD 17 Levee Seepage Repair Project is a program of levee repairs and improvements for 19 miles of levee along the San Joaquin River and Walthall Slough. This program is being implemented in three phases. The overall purpose of the program is to repair levee geometry to meet Federal and State levee standards, and to improve levee performance to better address under- and through-seepage. Most improvements are on, or landward of, the existing levee. The Phase 1 Project was completed in 2009. The Phase 2 Project was completed in summer 2010. The Phase 3 Project is the subject of this consultation.

To implement the Phase 3 Project, RD 17, through the Central Valley Flood Protection Board, is requesting permission from the U.S. Army Corps of Engineers pursuant to Section 14 of the Rivers and Harbors Act of 1899 (title 33 of the United States Code [USC], Section 408 [33 USC 408], referred to as Section 408, for alterations of Federal projects. RD 17 is also seeking a permit under Section 404 of the Clean Water Act (33 USC 1344) for placement of fill into jurisdictional waters of the United States.

The following information is provided to your office to initiate consultation:

A description of the action to be considered: The proposed levee modifications would involve: (1) installing approximately 3.3 miles of soil and bentonite cutoff walls; (2) constructing 0.64 miles of seepage berms; (3) constructing a 1,240 foot-long setback levee to restore at least 4.52 acres of floodplain; and (4) filling 0.77 acres of Waters of the United States, including wetlands, and other associated upland fill. A more detailed description of the proposed action is provided in Table 2 ("Summary of Major Activities Proposed for Each Element; Preferred Alternative") of the Enclosed BA. This work would eliminate or reduce levee deficiencies, including through- and under-seepage, slope stability, erosion and encroachments, within the construction footprint.

Details of RD 17's preferred alternative are provided in the enclosed BA and accompanying CD. The CD contains the 65 percent engineering designs plans for the preferred alternative. RD 17 proposes to construct the project over two construction seasons.

A description of the specific area that may be affected by the action: The work proposed as part of the Phase 3 Project would involve modifying approximately 5.3 miles of the Federal levee on the east bank of the San Joaquin River to reduce the potential for flooding, flood damage, and public risk in RD 17. Exhibit 2 of the enclosed BA shows the location of the proposed Phase 3 work. It also depicts levee work completed as part of the earlier Phase 1 and Phase 2 projects. Site specific details are shown in the enclosed BA in Exhibits 4a through 4c, and 13a through 13c.

A description of any listed species or critical habitat that may be affected by the action: We have determined that the proposed action may affect, but is not likely to adversely affect, Central Valley steelhead DPS, Central Valley spring-run Chinook salmon ESU, and the Southern DPS of North American green sturgeon.

A description of the manner in which the action may affect any listed species or critical habitat and analysis of any cumulative impacts: The Phase 3 Project would involve constructing several cutoff walls, which would entail degrading the top one-third to one-half of the levee. The degrade would begin at the waterside edge of the levee crown and would be accomplished without disturbing the waterside levee face. Exhibit 8 in the enclosed BA shows this measure. Implementing cutoff walls as part of the Phase 3 Project would disturb soils along the top of the levee which, through wind and water erosion, could enter the San Joaquin River. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately be pumped into the San

Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff. Through the implementation of water quality best management practices, including a Stormwater Pollution Prevention Plan, the proposed conservation measures (see pages 30 and 31 of the enclosed BA), would avoid direct and indirect take of fish during construction.

A setback levee would be constructed along one segment and the existing project levee would be modified to allow high water to flow onto the floodplain between the existing levee and the new setback levee. Fish and other aquatic organisms would likely flow onto the floodplain. The offset area would be contoured to drain back into the San Joaquin River as the water recedes in a manner that would avoid trapping fish landward of the existing levee. This is described in greater detail on page 23 of the enclosed BA.

Relevant reports including any environmental impact statement, environmental assessment, or biological assessment prepared: A copy of the February 2017, "Phase 3 – RD 17 Levee Seepage Repair Project, Final Biological Assessment" (BA), prepared by GEI, is enclosed.

Any other relevant available information on the action, the listed species, or critical habitat: See the enclosed BA.

This constitutes the best scientific and commercial data available. If you need additional information, or determine that conditioning the permit and letter of permission or modifying the project would preclude the need for formal consultation, please contact us immediately.

A copy of this letter, with the enclosure, will be furnished to Mr. Howard Brown, National Marine Fisheries Service, 650 Capitol Mall, Suite 5-100, Sacramento, California 95814-4700. Copies of the letter will also be furnished: to Dr. Steve Schoenberg, U.S. Fish and Wildlife Service, 2800 Cottage Way, Suite W-2605, Sacramento, CA 95825-1846; Mr. Dante Nomellini, c/o Nomellini, Grilli & McDaniel, P.O. Box 1416, Stockton, CA 95201; Mr. Henry Long, President, Reclamation District No. 17, P.O. Box 1461, Stockton, CA 95201; and Dr. Andrea Shephard, GEI Consulting, Inc. 2868 Prospect Park Drive, Suite 400, Rancho Cordova, CA 95670.

If you have any questions, please contact Ms. Tanis Toland, Environmental Manager, at (916) 557-6717 or by email at Tanis.J.Toland@usace.army.mil.

Sincerely,

Mark T. Ziminske

INTRODUCTION

The purpose of this biological assessment (BA) is to review Phase 3 of the proposed Reclamation District No. 17 (RD 17) Levee Seepage Repair Project (LSRP) (Phase 3 Project) in sufficient detail to determine the extent to which the proposed action may affect any of the federally listed species described below under "Species Considered." (See "Project Background and History" below for a brief summary of the previous Phase 1 and Phase 2 Projects.)

RD 17, which is located in south-central San Joaquin County, California (**Exhibit 1**; see Appendix A for all exhibits), includes 19 miles of levees along the east bank of the northern end of the San Joaquin River and along the north bank of Walthall Slough. These levees have been divided into seven distinct "reaches" identified by Roman numerals (i.e., I, II, III…, VII), and subdivided further into 19 "elements," identified by the reach number followed by a lowercase letter and, where needed to further distinguish elements, an Arabic numeral (e.g., Ia, IIa, IIb, …, Va, VIa.1, VIa.2, VIa.4, …, VIe, VIIa, VIIb, …, VIIg) (**Exhibit 2**).

This BA has been prepared in accordance with requirements set forth under Section 7 of the federal Endangered Species Act (ESA) (16 United States Code [USC] 1536[c]). It serves to initiate formal consultation with the U.S. Fish and Wildlife Service (USFWS) and informal consultation with the National Marine Fisheries Service (NMFS) on effects of the Phase 3 Project on federally listed species. This BA also serves to initiate consultation with NMFS on essential fish habitat (EFH) conservation recommendations for Pacific salmon (*Oncorhynchus* spp.), as required by the Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801). (See the "Essential Fish Habitat Assessment" section below.)

Section 7(a)(2) of the ESA directs federal agencies to ensure that their activities are not likely to jeopardize the continued existence of any listed species, or to result in the destruction or adverse modification of critical habitat. This section of the ESA also requires agencies with regulatory authority over listed species to issue biological opinions evaluating the direct and indirect effects of federal actions, and actions that are interrelated or interdependent with the federal action. The biological opinions must determine whether the actions being evaluated may appreciably reduce the listed species' likelihood of surviving or recovering in the wild by reducing their productivity, numbers, or distribution.

To implement the Phase 3 Project, RD 17 is requesting permission from the U.S. Army Corps of Engineers (USACE) for:

- alteration of federal project levees, pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408, referred to in this BA as "Section 408"); and

- placement of fill in jurisdictional waters of the United States, pursuant to Section 404 of the Clean Water Act (33 USC 1344, referred to in this BA as "Section 404").

All Phase 3 Project work occurring on the water side of the levee will be above the high tide line (HTL). Therefore, no additional authorizations under Section 10 of the Rivers and Harbors Act of 1899 are required.

These activities are described in more detail under "Description of the Proposed Action." This BA analyzes direct, indirect, interrelated/interdependent, and cumulative effects of the proposed action on federally listed species.

This page intentionally left blank.

SPECIES CONSIDERED

This document considers species that have been termed "threatened" or "endangered" under the jurisdiction of USFWS and NMFS. On February 27, 2014, biologists consulted the online database maintained by USFWS's Sacramento Office to conduct a query of the Lathrop (462D) and West Sacramento (462A) 7.5-minute quadrangles (USFWS 2014) (Appendix B). Using the California Department of Fish and Wildlife's (CDFW's) California Natural Diversity Database (CNDDB) (2014) and the California Native Plant Society's database of rare and endangered plant species (CNPS 2014), biologists also conducted a query of the topographic quadrangles in which the action area occurs (Lathrop and Stockton West) and the surrounding quadrangles; these database queries were conducted on February 27, 2014, and March 3, 2014, respectively (Appendix B). This query identified all listed species in the area surrounding the action area, which is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 Code of Federal Regulations [CFR] 402.02).

Based on these database queries and the biologists' familiarity with local flora and fauna, 21 plant and wildlife species that are federally listed as endangered or threatened, or are federally proposed for listing, were considered as part of this assessment (**Table 1**).

The following federally proposed and federally listed species are known to occur or have the potential to occur in the Phase 3 Project area (USFWS 2014):

- valley elderberry longhorn beetle (VELB) (*Desmocerus californicus dimorphus*),
- riparian brush rabbit (Sylvilagus bachmani riparius),
- delta smelt (Hypomesus transpacificus),
- Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*),
- longfin smelt (Spirinchus thaleichthy),
- Sacramento River winter-run Chinook salmon evolutionarily significant unit (ESU) (*O. tshawytscha*),
- Central Valley spring-run Chinook salmon ESU (*O. tshawytscha*), and
- the Southern DPS of North American green sturgeon (*Acipenser medirostris*).

The other federally listed species identified in Table 1 were eliminated from further consideration because they are not likely to occur in the Phase 3 Project area because of a lack of suitable habitat, local range restrictions, regional extirpations, or lack of connectivity between areas of suitable or occupied habitat, or because the action area is located outside of the extant range of the species (see "Action Area" section below). The USFWS-regulated species with the potential to occur on-site are discussed in more detail in this BA.

SPECIES HABITAT AND POTENTIAL FOR OCCURRENCE IN THE AREA

The following is a summary of relevant habitat conditions in the action area for species that could occur, are likely to occur, or are known to occur in the Phase 3 Project area. Full species accounts for federally listed species addressed in this BA are presented in the section titled "Species Accounts."

- **Valley elderberry longhorn beetle:** Elderberry shrubs provide habitat for VELB. Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3

Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than one inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

Table 1
Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the RD 17 Levee Seepage Repair Project

Species	Status	Habitat	Potential to Occur in the Lower San Joaquin River[1]
Plants			
Large-flowered fiddleneck *Amsinckia grandiflora*	Endangered[2] SJMSCP-covered[4]	Annual herb with bright orange, trumpet-shaped flowers that bloom in late spring. Historically found on north-facing slopes in the upper elevations of grasslands near the blue oak belt in Contra Costa, Alameda, and San Joaquin Counties.	No potential to occur. No suitable habitat is present within the action area.[3]
Palmate-bracted bird's-beak *Cordylanthus palmatus*	Endangered[2]	Annual herb that blooms from late spring through summer. Grows on seasonally flooded, saline-alkali soils in lowland plains and basins at elevations of less than 500 feet. Known from scattered locations in the Sacramento and San Joaquin Valleys; however, unlikely to occur in San Joaquin County because of lack of alkali habitat.	No potential to occur. No suitable habitat is present within the action area.[3]
Invertebrates			
Conservancy fairy shrimp *Branchinecta conservatio*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present within the action area.[3]
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	Threatened SJMSCP-covered[4]	Inhabits elderberry shrubs, primarily in riparian woodland and scrub habitat.	Could occur; elderberry shrubs present occasionally along the San Joaquin River on the waterside and landside of the Phase 3 Project levee; however, no evidence of beetle exit holes was observed in these shrubs.
Vernal pool fairy shrimp *Branchinecta lynchii*	Threatened SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present within the action area.[3]
Vernal pool tadpole shrimp *Lepidurus packardi*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present within the action area.[3]
Fish			
Central Valley steelhead *Oncorhynchus mykiss*	Threatened	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin Rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Designated critical habitat is in the action area.

Table 1
Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the RD 17 Levee Seepage Repair Project

Species	Status	Habitat	Potential to Occur in the Lower San Joaquin River[1]
Central Valley fall-/ late fall–run Chinook salmon *Oncorhynchus tshawytscha*	Species of Concern[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin Rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Essential fish habitat for this species is within the Phase 3 Project area.
Delta smelt *Hypomesus transpacificus*	Threatened[2] SJMSCP-covered[4, 5]	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears seasonally in inundated floodplains, tidal marsh, and the Delta.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin Rivers, tributaries, and Delta. Although no spawning habitat is in the action area, delta smelt has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Longfin smelt *Spirinchus thaleichthys*	Candidate/ Proposed Threatened[2] SJMSCP-covered[4, 5]	Pelagic estuarine. Ranges from the Delta in California northward to the Cook Inlet in Alaska.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin Rivers, tributaries, and the Delta. Although no spawning habitat is in the action area, longfin smelt has potential to occur in the San Joaquin River in the action area.[3]
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	Endangered[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. No spawning habitat is in the action area. Unlikely to occur in the San Joaquin River in the action area[3]; however, occasional adult and/or juvenile strays may be present.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	Threatened[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. Currently unlikely to occur in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. However, occasional adult and/or juvenile strays may be present. The SJRPP[6] includes the reintroduction of this species (an experimental population) to the San Joaquin River, so this species may occur in the river as early as 2014.
Green sturgeon *Acipenser medirostris*	Threatened SJMSCP-covered[4, 5]	Requires seasonally inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur. Occurs in the Sacramento and San Joaquin Rivers, tributaries, and the Delta. Has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Amphibians and Reptiles			
California red-legged frog *Rana draytonii (=R. aurora draytonii)*	Threatened SJMSCP-covered[4]	Prefers semi-permanent and permanent stream pools, ponds, and creeks with emergent riparian vegetation and typically without predatory fish. Requires adequate hibernacula such as small-mammal burrows and moist leaf litter.	No potential to occur. Although potential aquatic habitat in the Phase 3 Project area is limited to one constructed pond, likely with predatory fish, the action area is outside of the species' extant range.

Table 1 Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the RD 17 Levee Seepage Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
California tiger salamander *Ambystoma californiense*	Threatened[2] SJMSCP-covered[4]	In winter, breeds in vernal pools and stock ponds that are fish-free and inundated for a minimum of 12 weeks. In summer, aestivates in rodent borrows in grassland habitat.	Unlikely to occur. Potential aquatic habitat in the Phase 3 Project area is limited to one constructed pond, likely with predatory fish; a small area of freshwater marsh in Element Ib[7]; and agricultural ditches. Much of the action area consists of urban and agricultural land not suitable as potential upland habitat. A 1996 CNDDB record documents California tiger salamander adjacent to State Route 120 in roadside seasonal wetland; however, it is approximately 2 miles east of the San Joaquin River and geographically isolated.
Giant garter snake *Thamnophis gigas*	Threatened[2] SJMSCP-covered[4]	Streams, sloughs, ponds, and irrigation/drainage ditches; also requires upland refugia not subject to flooding during the snake's inactive season.	Unlikely to occur. While potential habitat for this species is present in the Phase 3 Project area, none of it is suitable. The only documented occurrences of giant garter snake are separated from the Phase 3 Project area by extensive urbanized development (City of Stockton) and large rivers that do not provide suitable habitat and are a greater distance than the species is known to disperse. For additional information that summarizes the rationale that supports the "unlikely to occur" determination for this species in the Phase 3 Project area, refer to Appendix C in this document.
Birds			
Least Bell's vireo *Vireo bellii pusillus*	Endangered[2]	Nests in riparian habitat adjacent to riverine and freshwater marsh.	Unlikely to occur. Although suitable habitat is present, the last recorded observation of this species in the action area was in 1878, with no extant occurrences.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	Threatened SJMSCP-covered[4]	Insect-feeder that forages in dense riparian oak forest canopy along major rivers. Species is considered extirpated from San Joaquin County.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Project area, the action area is outside of the species' extant range.
Mammals			
San Joaquin kit fox *Vulpes macrotis mutica*	Endangered SJMSCP-covered[4]	Annual grassland or grassy open stages with scattered shrubby vegetation; needs loose-textured sandy soils for burrowing, and suitable prey base.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Project area, the action area is outside of the species' extant range.
Riparian brush rabbit *Sylvilagus bachmani riparius*	Endangered[2] SJMSCP-covered[4, 5]	Inhabits riparian oak forest with dense understory of wild roses, grapes, and blackberries; small home ranges, seldom moving more than a few feet from cover, avoiding large openings in shrub cover and frequenting small clearings	Known to occur. Occupied riparian habitat is present on the waterside of Elements IIIa and IIIb, and suitable habitat is present immediately adjacent to the project area in several elements; species also is known to occur on an oxbow between Elements VIa.1 and VIa.4[7] and in waterside habitat between Elements IIab and IIIa.

Table 1 Fish and Wildlife Species Federally Listed or Proposed for Listing that Were Considered in the Evaluation of the RD 17 Levee Seepage Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
Riparian (=San Joaquin Valley) woodrat *Neotoma fuscipes riparia*	Endangered SJMSCP-covered[4]	Requires healthy riparian forests, where it nests in cavities in trees, snags, or logs, spaces in talus, or lodges built of downed woody materials. Known to exist in and immediately adjacent to Caswell Memorial State Park, along the Stanislaus River in San Joaquin County.	No potential to occur. The action area is outside of the species' extant range.

Notes: CNDDB = California Natural Diversity Database; Delta = Sacramento–San Joaquin Delta; Phase 3 Project = Phase 3 of the proposed Reclamation District No. 17 Levee Seepage Repair Project; SJMSCP = San Joaquin Multi-Species Habitat Conservation and Open Space Plan; SJRRP = San Joaquin River Restoration Program

1 **Potential for Occurrence Definitions:**

No potential to occur; Suitable habitat is not present in the Phase 3 Project area and/or the Phase 3 Project area is not within the historical or current range of the species.

Unlikely to occur: Potential habitat present, but species unlikely to be present in the Phase 3 Project area because of current status of the species, a very restricted distribution, and/or essential habitat components are not present.

Could occur: Suitable habitat is available in the Phase 3 Project area; however, there are few or no other indicators that the species may be present.

Likely to occur: Habitat conditions, behavior of the species, known occurrences in the Phase 3 Project area, or other factors indicate a relatively high likelihood that the species would occur in the Phase 3 Project area.

Known to occur: The species, or evidence of its presence, was observed in the Phase 3 Project area during reconnaissance-level surveys or was reported by others.

2 These species have a similar status listing under the California Endangered Species Act, except for delta smelt and western yellow-billed cuckoo, which are both state listed as endangered, and longfin smelt and San Joaquin kit fox, which are both state listed as threatened.

3 Action Area: The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Project. Areas downstream of the Phase 3 Project area may also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions.

4 SJMSCP-covered: These species are covered under the SJMSCP (San Joaquin County 2000).

5 SJMSCP-covered with limitations: The SJMSCP does not cover the conversion of occupied riparian brush rabbit habitat, limits the amount of delta smelt habitat, and does not authorize take of green sturgeon.

6 See "San Joaquin River" subsection under "Environmental Baseline" section below, for more information.

7 Elements: The RD 17 levees have been divided into 7 distinct "reaches" identified by Roman numerals (i.e., I, II, III), and subdivided further into 19 "elements," identified by the reach number followed by a lowercase letter and, in some cases, an Arabic numeral (e.g., Ia, IIa, Va, VIa.1…); see **Exhibit 2**.

Sources: CNDDB 2014, CNPS 2014, USFWS 2014; data compiled by AECOM in 2014

- **Riparian brush rabbit:** Trapping conducted in February 2003 and February 2004 detected occurrences of riparian brush rabbit near the Phase 3 Project area in waterside riparian habitat adjacent to Elements IIIa and IIIb, between Elements IIab and IIIa, and between Elements VIa.1 and VIa.4 (CNDDB 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004). The waterside habitat along Elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The trapping locations between Elements IIab and IIIa are dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The trapping locations between Elements VIa.1 and VIa.4 are on an oxbow with dense riparian vegetation. Similar riparian habitat is present adjacent to the waterside of Phase 3 Project area Elements IIab, IVc, and Va. North of Element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, or isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species.

- **Delta smelt:** Delta smelt are found from Suisun Bay upstream through the Sacramento–San Joaquin Delta (Delta). Delta smelt disperse widely into freshwater in late fall and winter as the spawning period approaches, and may move as far upstream as Mossdale on the San Joaquin River (Bennett 2005). Therefore, this species has the potential to occur in the Phase 3 Project area.

- **Longfin smelt:** Longfin smelt occur in the Delta and tidally influenced segments of the Sacramento and San Joaquin Rivers. The occurrence of longfin smelt in the San Joaquin River is rare, but it does occur on occasion when river salinity extends farther upstream, either as a result of Delta pumps or because of drought. Therefore, this species has the potential to occur in the Phase 3 Project area.

- **Anadromous salmonids:** The action area (see "Action Area" section below) does not provide suitable spawning habitat for salmonids because it lacks the cold freshwater and gravel substrate characteristic of salmonid spawning areas in upper river basins. However, adult and juvenile Central Valley fall-run Chinook salmon and Central Valley steelhead could occur in the action area during migrations along the San Joaquin River and its tributaries. Winter-run and spring-run Chinook salmon are known to occur only in the Sacramento River and its tributaries (Moyle 2002). Because the action area is along the San Joaquin River, several miles upstream of its confluence with the Sacramento River, adult migrants along the Sacramento River are not expected to move into the action area. However, with the implementation of the San Joaquin River Restoration Project (SJRRP) (see "San Joaquin River" subsection under "Environmental Baseline" below), an experimental population of spring-run Chinook salmon will be reintroduced to the San Joaquin River beginning in 2014 to achieve one of the goals of the SJRRP, which is "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River…including naturally reproducing and self-sustaining populations of salmon and other fish" (NMFS 2013).

- **Green sturgeon:** Green sturgeon is known to occur in the San Joaquin River and therefore has the potential to occur in the lower San Joaquin River and Delta at the project site (Moyle 2002). Green sturgeon spawning in the San Joaquin River is not well documented.

CRITICAL HABITAT

"Critical habitat" is defined in Section 3(5)A of the ESA as the specific areas in the geographical area occupied by the species where physical or biological features are found that are essential to the conservation of the species and that may require special management considerations or protection. Specific areas outside of the geographical area occupied by the species may also be included in critical-habitat designations, based on a determination that such areas are essential for the conservation of the species.

The proposed action addressed in this BA falls within designated critical habitat for delta smelt, which was designated on December 19, 1994 (59 *Federal Register* [FR] 65256). Critical habitat is designated to include most tidally influenced areas of the Delta.

The proposed action addressed in this BA falls within designated critical habitat for the Central Valley steelhead DPS. Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area (see "Action Area" section below).

The proposed action addressed in this BA falls within designated critical habitat for the Southern DPS of North American green sturgeon. Critical habitat for green sturgeon was designated on October 9, 2009 (74 FR 52300).

Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

The action area is not within designated critical habitat for the remaining species listed in **Table 1** for which such a designation has been made: large-flowered fiddleneck, Conservancy fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, VELB, Sacramento River winter-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, California red-legged frog, California tiger salamander, and least Bell's vireo. Critical habitat has not been designated for palmate-bracted bird's-beak, longfin smelt, Central Valley fall-/late fall–run Chinook salmon ESU, giant garter snake, western yellow-billed cuckoo, San Joaquin kit fox, riparian brush rabbit, or riparian woodrat.

SAN JOAQUIN MULTI-SPECIES CONSERVATION PLAN

All of the above species, except the anadromous salmonid fish species, are covered on some level under the *San Joaquin Multi-Species Habitat Conservation and Open Space Plan* (SJMSCP) (San Joaquin County 2000). The SJMSCP was developed to avoid, minimize, and mitigate impacts on plant and wildlife habitat projected to occur in San Joaquin County between 2001 and 2051, resulting from the anticipated conversion of open space land to non–open space uses. Ninety-seven species are covered by the SJMSCP. The plan is intended to provide comprehensive mitigation, in accordance with local, state, and federal regulations, for impacts of SJMSCP-permitted activities on these species. USFWS and CDFW participated in development of the SJMSCP, approved the mitigation, and agreed to issue incidental take permits for species and activities covered by the SJMSCP.

The geographic area covered in the SJMSCP extends up to the landside levee crown of the San Joaquin River levee and would include the Phase 3 Project area. However, the SJMSCP does not cover federal flood risk management projects or activities involving tidally jurisdictional wetlands or other waters of the United States, and thus, the Phase 3 Project is not a covered activity under the SJMSCP. The SJMSCP outlines a mechanism by which a federal flood risk management project such as the Phase 3 Project could obtain take coverage under the SJMSCP (see Section 8.2.3 of the SJMSCP). However, because the SJMSCP does not cover special-status fish, the conversion of riparian brush rabbit habitat, or impacts on other species on the waterside of the levee, RD 17 and USACE would not rely on the SJMSCP to assess and offset Phase 3 Project effects on federally listed and state-listed species. Rather, through this BA and the associated Section 7 consultations with USFWS and NMFS, RD 17 and USACE would seek take authorization for Phase 3 Project activities. Species listed under the California Endangered Species Act that are also covered species under the SJMSCP would be evaluated through consultation with CDFW.

This page intentionally left blank.

CONSULTATION TO DATE

The list below summarizes correspondence, meetings, and discussions between regulatory agencies, RD 17, and consultants that relate to potential impacts of the Phase 3 Project on species addressed in this document. The most recent consultation is listed first.

2/27/14 Letter from USFWS to AECOM regarding *Species List for RD 17 100-Year Levee Seepage Area Project*[1].

3/1/11 Tour of proposed action area with representatives of AECOM, USACE, USFWS, NMFS, and CDFW.

1/24/11 Meeting with representatives of USFWS and AECOM to discuss project permitting coordination, the potential impacts of the project on federally listed species, and the development of a conservation strategy.

12/9/10 Meeting with representatives of CDFW and AECOM to discuss project permitting coordination, the potential impacts of the project on state-listed species, use of the SJMSCP, and the development of a conservation strategy.

8/24/10 Meeting with representatives of USACE, USFWS, NMFS, and AECOM to discuss the potential impacts of the project on listed species and the development of a conservation strategy.

6/11/10 Letter from NMFS to AECOM, responding to May 14, 2010, letter requesting technical assistance (Appendix D).

5/14/10 Letter from AECOM, prepared on behalf of RD 17, to USFWS and NMFS requesting informal technical assistance in evaluating the potential impacts on listed species that could result from implementing USACE vegetation management standards, and in developing a conservation strategy that could adequately offset the potential loss of habitat. Copies of the wetland delineation report and maps were provided with the letter (Appendix D).

[1] "RD 17 100-Year Levee Seepage Area Project" is a reference to the RD 17 Levee Seepage Repair Project. This former name was used in documents published prior to preparation of the Final Environmental Impact Statement for Phase 3 of the RD 17 Levee Seepage Repair Project.

DESCRIPTION OF THE PROPOSED ACTION

U.S. ARMY CORPS OF ENGINEERS ACTION

RD 17, in cooperation with the California Department of Water Resources (DWR) and the Central Valley Flood Protection Board (CVFPB), is the local project sponsor for the Phase 3 Project. RD 17 has requested permission from the CVFPB and USACE to alter segments of the San Joaquin River Levee System, which is a federal project levee. The proposed action for USACE is to make a permit decision on Phase 3 of the LSRP under the authority of Clean Water Act Section 404 and Section 408 of Title 33 United States Code. Under Section 408, USACE may allow the permanent use or occupancy of a USACE flood risk management project with approval by the Secretary of the Army on recommendation of the Chief of Engineers, provided that such use or occupancy would not be injurious to the public interest. USACE has determined that a 408 decision would be required for alterations to the RD 17 levees. The activities requiring Section 408 and/or 404 authorization, described in more detail below, include proposed alterations/improvements to USACE flood risk management facilities and fill of jurisdictional waters during earth-moving activities for levee construction. Activities for the Phase 3 Project will be processed through an encroachment permit with the CVFPB. USACE would conduct a technical engineering review as part of the CVFPB's consideration of the encroachment permit application, in accordance with USACE regulations contained in 33 CFR 208.10.

PROJECT LOCATION

RD 17 is located in south-central San Joaquin County, California, in the center of the California Central Valley, at the north end of the San Joaquin River Basin, and within the far southeast limit of the Sacramento–San Joaquin Delta (Delta) (**Exhibit 1**). The boundaries of RD 17 are marked by French Camp Slough on the north, approximately 3 miles southwest of the central business district of the City of Stockton; the San Joaquin River on the west; Walthall Slough on the south (just below State Route 120); and Airport Way/McKinley Avenue on the east, just outside the City of Manteca. RD 17 is responsible for maintaining the levees along Walthall Slough, the San Joaquin River, and French Camp Slough, as well as a dryland levee along the southern boundary of Manteca (**Exhibit 2**). The dryland levee is an overland earthen berm north and east of the San Joaquin River.

Under almost all conditions water does not come in contact with the dryland levee. It only functions as a flood risk management feature if water from the San Joaquin River or Walthall Slough leaves the banks of these waterways and inundates lands to the north and east toward Manteca. The dryland levee then acts as an elevated earthen feature that prevents these flood waters from moving farther north.

PROJECT BACKGROUND AND PURPOSE

PROJECT BACKGROUND AND HISTORY

The RD 17 system for reducing the risk of flood damage, like other flood protection systems in the San Joaquin Valley, was initially designed to facilitate agricultural development on the extensive valley floodplains and support river navigation. Levees set closely along the rivers were designed to contain flows generated by common floods, and bypasses were constructed to carry overflows generated by large floods. The close-set levees ensured that water velocities would help scour the river bottom and move sediment through the system, reducing dredging costs for sustaining navigation. Starting in about 1863, RD 17 began constructing or reconstructing the RD 17 levee system.

Some of the levees in the Delta are considered "federal project levees." These levees were constructed or reconstructed (e.g., existing or damaged farm levees were improved) by USACE and are intended to meet federal standards. Construction of the federal levee system that encompasses the current RD 17 levees along Walthall

Slough, the San Joaquin River, and French Camp Slough began in 1944 and was completed in 1963. The levee system has since been upgraded substantially to meet Federal Emergency Management Agency (FEMA) requirements for flood protection during a 100-year flood event. In 1990, after extensive analysis, the RD 17 levees were accredited by FEMA as meeting the 100-year requirements for urban development.

During a high-water event on the San Joaquin River in January 1997, seepage and boils occurred at several locations along the RD 17 levees. USACE, DWR, and RD 17 successfully contained the seepage and boils and the levees did not break. After the 1997 event, USACE, the CVFPB, and RD 17 funded a project, the Reconstruction of the California Central Valley Levees San Joaquin Basin #4, Reclamation District #17 Project, to repair the seepage and boil areas. The project was constructed by USACE and work was completed in 2003.

After reviewing the data supporting the 1990 accreditation and subsequent information, FEMA notified RD 17 of its intention to confirm full accreditation of the RD 17 levees as meeting FEMA's requirements for 100-year flood protection. On June 19, 2007, DWR wrote to the City of Lathrop, with a copy to FEMA, stating that it could not support recertification of the RD 17 levees or the granting of provisional accreditation because of concerns about seepage exit gradients.[2] The basis of DWR's concern was analysis showing seepage exit gradients greater than 0.5, which indicated a higher likelihood of seepage or boils occurring during a high-water event. Based on DWR's concern, FEMA then denied full accreditation and instead granted provisional accredited levee (PAL) status. A PAL is a levee that FEMA has previously credited with providing a 100-year level of flood risk reduction (flood with a 1% chance of occurring in any given year, or 0.01 annual exceedance probability). In the fall of 2007, in response to the PAL status, RD 17 initiated a levee seepage repair program and requested funding through DWR's Early Implementation Program.

RD 17 subsequently implemented Phases 1 and 2 of the LSRP. After completion of the Phase 1 and 2 levee improvements, RD 17 submitted a recertification application to FEMA. In September 2010, RD 17 received a response letter declaring that FEMA had accredited the area protected by the RD 17 levee system, including the dryland levee, thereby removing the PAL status.

The Phase 1 Project involved constructing two seepage berms located in Elements III and VI of the LSRP (**Exhibit 2**). The project reconstructed and extended the landside levee toe berms with earth and gravel fill, both landward and along the levee toe, to reduce seepage exit gradients. Work areas were designed to avoid any environmental resources of possible significance, including sensitive habitats and listed species. The project was determined to be categorically exempt from the California Environmental Quality Act (CEQA) and no federal authorizations or funding were required for the Phase 1 work; therefore, no National Environmental Policy Act (NEPA) analysis was triggered. The Phase 1 Project work was completed in January 2009.

The Phase 2 Project addressed work needed at nine levee reaches in the LSRP area. At eight of the nine reaches, the project constructed drained seepage berms along the landside levee toe. At one site that did not include seepage berm construction, RD 17 acquired an easement on land along the levee toe and performed various maintenance and site cleanup activities. A CEQA initial study/mitigated negative declaration that was completed for the Phase 2 Project concluded that no significant effects would occur on environmental resources after mitigation measures were implemented (RD 17 2009). Potential impacts on biological resources that resulted from Phase 2 Project implementation were mitigated through participation in the SJMSCP. No federal

---

2 "Seepage exit gradient" is an expression in numeric form of the potential for under seepage to exit on the landside of a levee as seepage or a boil. The lower the number used to express seepage exit gradient, the more resistant the system is to seepage or boils; the higher the number, the more likely seepage or boils may occur during a high-water event. In formulas for seepage exit gradients, the numerator (top number in a fraction) typically addresses forces that cause or enhance seepage (e.g., water pressure), and the denominator typically addresses forces that resist seepage (e.g., soil resistance to water pressure, depth and weight of soil over the potential seepage area, distance from the levee toe). A lower seepage exit gradient (i.e., more resistance to seepage) is achieved when the numerator (positive seepage forces) is reduced and/or the denominator (resistance to seepage) is increased.

authorizations or funding were required for the Phase 2 work; therefore, no NEPA analysis was triggered. All Phase 2 Project work was completed in summer 2010.

PROJECT PURPOSE AND OBJECTIVES

The overall purpose of the Phase 3 Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.3 miles of the approximately 19-mile RD 17 levee system to improve the existing levee integrity based on the new USACE standards and continue to provide flood risk reduction within RD 17 and surrounding areas. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation. USACE and RD 17 each view the project purpose from the purview of their respective responsibilities, as defined below.

USACE's objectives for the Phase 3 Project are to:

- decide whether or not to grant permission for RD 17's Phase 3 Project to alter the federal project levees within its levee system under Section 408, and
- decide whether or not to issue permits under Section 404.

RD 17's objectives for the proposed Phase 3 Project are to:

- correct levee geometry where needed to meet USACE design standards,
- increase the levee's resistance to under seepage and/or through seepage, and
- provide under seepage exit gradients equal to or less than 0.5 at the landside levee toe, and equal to or less than 0.8 at the landside drainage seepage berm at the water surface elevation associated with the design water surface.

All Phase 3 Project work would occur above the HTL, on the water side of the levee, therefore, authorization under Section 10 of the Rivers and Harbors Act of 1899 would not be required. Authorization under Section 404 of the Clean Water Act would also not be required on the water side of the levee because work would occur above the HTL. Section 404 authorization would be required on the land side of the levee. USACE verified a wetland delineation submitted for Phase 3 of the RD 17 LSRP on November 3, 2009 (preliminary jurisdictional determination form was issued by USACE on November 10, 2009), and three supplemental wetland delineations were prepared. The first supplemental delineation was submitted on January 22, 2010 (preliminary jurisdictional determination form was issued by USACE on April 9, 2010). The second supplemental wetland delineation was submitted on September 16, 2010 (preliminary jurisdictional determination form was issued by USACE on October 7, 2010). The third supplemental wetland delineation was submitted on April 4, 2014 (preliminary jurisdictional determination form was issued by USACE on April 7, 2014).

COMPLIANCE WITH USACE VEGETATION MANAGEMENT STANDARDS

With issuance of Engineering Technical Letter (ETL) 1110-2-571, and subsequently with ETL 1110-2-583, USACE updated its vegetation management standards for levees, requiring the removal of all vegetation except perennial grasses on the levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2009, USACE 2014). Per the ETL, the "trunk (or stem), stump, rootball and all roots greater than ½-inch in diameter—all such roots in, or within 15 feet of, the flood damage reduction structure shall be completely removed" through excavation.

Public Law 84-99 authorizes USACE to provide rehabilitation assistance for levees as long as the system is operated and maintained to acceptable or minimally acceptable standards. However, on March 21, 2014, USACE issued a memorandum, "Interim Policy for Determining Eligibility Status of Flood Risk Management Projects for the Rehabilitation Program Pursuant to Public Law (P.L) 84-99," to provide interim criteria for determining eligibility for PL 84-99 assistance. Under this interim policy, vegetation management will not be considered in making a PL84-99 eligibility determination. Therefore, RD 17 is continuing its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which involves trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up 5 feet above the ground [or 12 feet above the crown road]. However, within the Phase 3 Project area, landside vegetation would be removed; only waterside vegetation would be managed in accordance with RD 17 existing practices.

DESCRIPTION OF THE PROPOSED PHASE 3 PROJECT

The Phase 3 Project would address the under seepage and/or through seepage concerns raised by DWR and repair and/or remediate levee geometry to USACE design standards along approximately 5.2 miles of the RD 17 levee system, including portions of the San Joaquin River east levee and portions of the levee along the northerly bank of Walthall Slough. Under seepage occurs below the aboveground levee prism and is caused by the buildup of water pressure in the subsurface foundation soils when high river stages are present on the waterside of the levees. This pressure head causes water to flow through the earthen foundation layers under the levee and exit onto the ground surface on the landside of the levee prism (**Exhibit 3**). Such seepage is not uncommon and does not inherently imply that the levee is failing; however, excessive and uncontrolled under seepage can carry fine-grained material with the water flow that can undermine the levee and can lead to levee failure. Through seepage is the movement of water through the levee prism when high river stage conditions exist on the waterside of the levee (**Exhibit 3**). Depending on the duration of high water and the permeability of the levee embankment soil, seepage may exit onto the landside slope of the levee, thereby negatively affecting the stability of the landside levee slope.

The BA does not address the dryland levee because it is not a USACE flood risk management project and therefore not subject to Section 408 authorization. Suitable habitat for federally listed species does not occur along the dryland levee. Levee improvements would consist primarily of in-place repair/remediation, but would include a single setback levee at Element IVc. As summarized in **Table 2** and depicted in **Exhibits 4a** through **4d**, the Phase 3 Project's landside levee improvements include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system. These levee improvement components, as well as additional project components such as levee geometry corrections and stormwater management, are described in more detail following Table 2. The proposed action does not include any work that would consist of raising the existing levee. Limited work would be performed along the waterside of the levee above the HTL, in Element IVc where the setback levee would be constructed.

LEVEE IMPROVEMENT COMPONENTS

The Phase 3 Project levee improvements would include seepage berms, chimney drains, cutoff walls, a setback levee, and a raised landside grade. **Table 2** briefly summarizes the activities proposed for each project element. The respective levee improvement components are described below in more detail.

SEEPAGE BERMS

Reducing the risk of levee failure caused by both under seepage and through seepage may be addressed by constructing a drained seepage berm. A drained berm collects and conveys seepage, thereby reducing the flood risk associated with a high-water event. A drained seepage berm is built on the landside, adjacent to a levee, and consists of layers of sand filter material, drain rock, geosynthetic filter fabric, and a seepage berm soil fill (**Exhibit 3**).

The drained seepage berm reduces flood risk during sustained high-river-stage events by collecting seepage that otherwise would flow onto the landside ground surface at and beyond the levee's landside toe of slope, and then by conveying the seepage away from the levee. The layer of sand filter material placed on the natural ground surface serves to reduce the transmission of fine-grained soils into the drain rock, thereby maintaining the drain rock's ability to be a conductive soil unit that conveys collected seepage. Similarly, the filter fabric that separates the drain rock from the seepage berm fill soil prevents finer soils from migrating into the drain rock unit. The weight of the berm acts as ballast, reducing the potential for detrimental boils and piping.

The design width and height of a seepage berm are dependent on the relative permeability of the underlying soil layers and the amount of pressure head pushing water under the levee and through the near-surface soils during sustained high-river-stage events. The higher the water pressure head acting on the near-surface soils on the landside of the levee prism, the wider and/or deeper the seepage berm must be to reduce flood risk.

For the Phase 3 Project, drained seepage berm widths of 65–125 feet would be adequate to meet the design criteria in most cases (**Exhibit 5**). However, these types of berms may extend up to 300–400 feet inland of the landside toe of the levee. Seepage berms are typically constructed using select materials excavated from borrow sites or obtained from commercial sources. In the case of the Phase 3 Project, soil material would be purchased from commercial sources. A compacted-surface patrol road would be constructed near the outside edge of the seepage berm (see "Additional Project Components" below).

In urban areas, some seepage berms would also include a toe drain system (Element VIIg) or a V-ditch (Element Ie) to safely collect and discharge the seepage water into an urban storm drainage system. A toe drain pipe is a below-grade, perforated pipe surrounded by a layer of sand and drain rock (**Exhibit 6**). The toe drain pipe is a mechanism to safely collect and convey seepage water away from the levee and seepage berm. If the toe drain pipe were unable to convey the seepage water, it would exit the seepage berm through the drain rock at the face of the berm similar to a nonurban berm.

CHIMNEY DRAINS

Chimney drains are drainage systems that collect seepage waters that are flowing through the aboveground portion of the levee structure. These drains are used to collect and convey through seepage. A chimney drain consists of a 1- to 3-foot-thick layer of sand and drain rock. Filter fabric is placed between the soil and rock layer to avoid migration of the soil into the rock, which could clog the rock layer and reduce its ability to carry seepage flows. The chimney drain is placed directly on the landside slope of the levee and tied into an existing or new seepage berm at the landside base of the levee (**Exhibit 7**); the height of the proposed chimney drains would vary from 5 to 20 feet above the elevation of the landside levee toe. The chimney drain conveys the through seepage flows to a seepage berm, which is located at the landside base of the levee.

Installing a chimney drain in an existing seepage berm would involve adding the through seepage material on top of the existing seepage berm, and tying this material into the existing seepage berm material by excavating off the seepage berm fill material and physically tying the two drainage rock layers together. Where the remediation involves construction of a new seepage berm with a chimney drain, the chimney drain would be installed during construction of the new seepage berm.

CUTOFF WALLS

In select locations of the Phase 3 Project, cutoff walls would be placed within the levee prism (parallel to the river). Cutoff walls use specialized earthen materials (often bentonite clay, which has low permeability). Cutoff walls would be constructed vertically through the levee prism, extending into or through deeper foundational soils that have low-permeability soil (a layer through which seepage does not flow readily). Cutoff walls would thus significantly reduce the potential for under and through seepage flow during high-river-stage events. Two

Table 2 Summary of Major Activities Proposed for Each Element: Preferred Alternative		
Element	**Type of Remediation**	**Proposed Activities**
Ia	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and install a 590-foot-long seepage berms (minimum 65 feet wide) with chimney drain to meet required exit gradients.
Ib	under seepage and through seepage	Fill existing depression to 300 feet from toe of existing levee; place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width; and install a 125-foot-long seepage berm (minimum 60 feet wide) with chimney drain on top of fill to meet required exit gradients.
Ie, IIIb, IVa, and VIIb	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and construct seepage berms with lengths of 655 feet (Ie), 720 feet (IIIb), 525 feet (IVa), and 385 feet (VIIb), and chimney drains to meet required exit gradients. Minimum seepage berm widths would vary (65–75 feet) depending on the element. For Element Ie, construct v-ditch from seepage berm to existing swale.
IIa and IIb	under seepage and through seepage	Install cutoff wall with a length of 2,550 feet to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.
IVc	under seepage and through seepage	Construct 1,240-foot-long setback levee with seepage berm and cutoff wall to meet required exit gradients. Seepage berm would be a minimum of 65 feet wide or four times levee height, whichever would be greater. Install riprap on waterside of existing levee above the high tide line where it would intersect setback levee. After setback levee is completed, remove 410 linear feet of the existing levee on downstream side of oxbow.
Va and VIa.1	under seepage and through seepage	Where feasible, place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 24-foot levee crown width and install cutoff walls with a length of 9,520 feet to meet required exit gradients. Depth of cutoff walls would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Open-cut method would be used for all cutoff walls.
IIIa	through seepage	Place levee fill material along landside of existing levee slopes where feasible to provide minimum 3:1 slopes and 20-foot levee crown widths and install chimney drain in existing 3,700-feet-long seepage berm to meet required exit gradients.
VIa.4	under seepage and through seepage	Install cutoff wall with length of 70 feet to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 26-foot levee crown width.
VIb, VIc, VId, and VIe	under seepage and through seepage	Install cutoff wall with length of 2,700 feet (VIbcde) to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall in levee prism would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown.
VIIe	under seepage and through seepage	Install DSM cutoff wall with a length of 2,500 feet to meet required exit gradients. Depth of cutoff wall would vary from 60–120 feet. Deep slurry mixing method would be used. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and levee crown width. Soil removed during levee degradation would be stockpiled on adjacent RD 17 property and used for rebuilding the levee at these locations or used for fill at other locations in the Phase 3 Project.
VIIg	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 26-foot levee crown width, and construct seepage berm with chimney drain with length 385 feet to meet required exit gradients. Minimum seepage berm width would be 65 feet.
Source: Data provided by Kjeldsen, Sinnock & Neudeck, Inc. in 2014		

methods for installing cutoff walls would be used along portions of the RD 17 levees: the open-cut method and the deep slurry mix method.

The open-cut method would be used to install shallow cutoff walls to a maximum depth of approximately 80 feet. This method involves excavating material in an open trench (the trench is filled with a bentonite slurry to maintain the side slopes of the excavation) and then replacing it with the select materials, typically a bentonite or cement-bentonite slurry (**Exhibit 8**). In this case, the top one-third to one-half of the levee height is "degraded," meaning that it is excavated to ensure that any weakness in the narrow upper portion of the levee would not fail during construction.

For the deep slurry mixing method, specialized equipment is used to excavate deep into the subsurface, allowing the cutoff walls to reach depths of up to 120 feet (**Exhibit 9**). The deep slurry mixing method involves mixing a soil-cement-bentonite mixture and replacing material as it is excavated during construction of the cutoff wall, thereby reducing the risk of failure during construction. This method does not require levee crown degradation.

Cutoff walls would be extended approximately 300 feet beyond the element boundary to provide the required overlap when seepage berms have been or are being installed along the landside of adjacent levee elements. Levee slopes where cutoff walls would be installed would also be modified as needed to achieve the required 3:1 slope.

SETBACK LEVEE WITH SEEPAGE BERM AND UNDERLYING CUTOFF WALL

A setback levee is a levee constructed some distance behind an existing levee. The setback is tied into the existing levee at the upstream and downstream ends of the setback area. All or a portion of the existing levee between these two points would be then typically removed to allow high-water events to inundate the newly expanded floodway. Soil from the old levee may be used as a source of fill for other flood protection improvement projects, depending on the quality and quantity of material generated from demolition of the old levee. In some cases, it may be necessary to continue maintaining the existing levee after a setback levee is constructed (e.g., to protect existing development in the setback area) and to use the newly constructed levee as a backup levee.

In the Phase 3 Project area, soil materials below a setback levee are anticipated to have properties similar to those of materials below the existing levees. Therefore, a setback levee would have no seepage-related benefit in the RD 17 area relative to other seepage control methods, and like the existing levees, a setback levee would require either a cutoff wall or seepage berm to sufficiently reduce the potential negative impacts of under seepage flows (**Exhibits 10** and **11**). Nonetheless, implementing a setback levee could provide some additional capacity in the river for floodwaters, and would also have the potential to provide environmental habitat in the area between the new and old levee locations. In the Phase 3 Project area, any newly expanded floodway created by a proposed setback levee would be designed to drain surface water after a high-water event to prevent fish stranding.

A setback levee with a seepage berm and an underlying cutoff wall is proposed for construction in Element IVc. As described in greater detail under Section 2.1.4 in the Draft Environmental Impact Statement/Environmental Impact Report (USACE and RD 17 2011), and consistent with Section 2.5.1 of the forthcoming Final Environmental Impact Statement (USACE *in prep.)* for the proposed project, setback levees were considered but eliminated from further consideration in several project reaches for the following reasons.

- Construction of a setback levee along certain stretches of the river were hydraulically constrained and would have greatly increased the project scope to the point of being cost prohibitive (Elements Ia, IVa, VIa.4, and VIb).
- Because of the proximity to the bifurcation at Old River, the change in hydraulic conditions that would result from constructing a setback levee at Elements Va and VIa.1 at this location would increase flows down the San Joaquin River during flood events, which could lead to increased flooding downstream (Elements Va and VIa.1).

- Land acquisition for construction of a setback levee was cost prohibitive (Elements Ie, IIab, IIIb, IVc, VIIb).
- Existing landside development constrained the option of constructing a setback levee (Elements VIIe and VIIg).
- A setback levee would have resulted in impacts on existing facilities and site constraints related to pedestrian and roadway crossings, Caltrans facilities, State boat launch facility, and other utilities (Element VIcde).

RAISED LANDSIDE GRADE

Directly adjacent to the landside toe of the levee in Element Ib, there is an approximately 5-foot-deep depression that was used as a borrow site to facilitate construction of the Howard Road Bridge. RD 17 would place fill within this depression to raise the landside grade.

ADDITIONAL PROJECT COMPONENTS

The following additional activities would occur as part of the Phase 3 Project:

- **Levee geometry corrections:** Many Phase 3 Project elements do not currently meet requirements for levee geometry (i.e., slopes, crown width). To correct levee geometry, levee fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot-wide levee crown.
- **O&M access and utility corridors:** A 20-foot-wide permanent O&M access corridor would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.
- **Temporary construction easements:** Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the sites returned to preproject conditions at the end of construction.
- **Stormwater management:** Drainage swales would be constructed around the outside of levee improvements, where needed, and other stormwater best management practices (BMPs) would be implemented to manage stormwater runoff during and after construction.
- **Right-of-way acquisition:** Lands within the Phase 3 Project footprint would be acquired as needed to accommodate levee improvements (e.g., seepage berms, setback levees) and establish the minimum 20-foot-wide O&M access corridor at the landside toes of all the improved levees, to prevent encroachment into the levee or seepage berm improvements. Privately owned lands would be acquired in fee but may be taken as easements if needed. Where the RD 17 project footprint would overlie land owned and managed by other agencies (i.e., the City of Lathrop, San Joaquin County, Union Pacific Railroad [UPRR]), either the land would have to be acquired in fee or easements would have to be obtained and secured. Real property acquisition and any relocation services (if needed—no relocations are anticipated) would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 USC 4601 et seq.) and implementing regulation, Title 49 of CFR Part 24, and California Government Code Section 7267 et seq.
- **Haul roads:** An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and concrete) would be required to construct these levee improvements. These materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Phase 3 Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would include public

roadways, on and within 300 feet of the levees; existing unpaved roads used for access to work areas; and levee patrol roads atop the levee crown.

- **Landside vegetation removal:** Landside vegetation within the footprint of the proposed levee improvements, including maintenance roadway corridors and temporary access easements, would be cleared to prepare for levee improvement work under the Phase 3 Project. These areas would be hydroseeded with a standard erosion control mix after construction activities are completed, and temporary construction easements would be returned to preproject conditions. The proposed action would involve performing limited work on the waterside of the levee above the HTL (e.g., installation of riprap and degrade of a portion of the levee in Element IVc); however, no waterside woody or riparian vegetation would be removed as the areas where the riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Encroachment management:** Several features are within the Phase 3 Project footprint: power poles, overhead and underground utilities, and a variety of agriculture-related items (e.g., irrigation and drainage infrastructure, fences). Utility infrastructure (power poles) would be relocated as needed to accommodate the levee improvements, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Phase 3 Project area would be removed or relocated as required to meet the criteria of USACE, the CVFPB, and FEMA.

PROPOSED SCHEDULE AND SEQUENCE OF PROJECT CONSTRUCTION

Construction of the Phase 3 Project is scheduled to begin in 2015 and is expected to be completed by December 2016, assuming receipt of all required environmental clearances, permits, and approvals for implementation. Some related activities, such as relocating power poles, might be conducted before levee work is initiated, and site restoration and demobilization could extend through spring 2017. The general levee construction window is seasonal (July 1–November 1) due to when high-water levels have the potential to occur within the San Joaquin River system. However, dependent on hydrologic conditions and subject to compliance with species work windows, a work window variance that allows for an extension outside the July 1–November 1 work period may be granted by CVFPB. CVFPB may stipulate that RD 17 comply with additional conditions and commitments as a component of any work window variance.

The proposed construction sequence, which would include concurrent work in several different elements to meet the project schedule, is as follows:

- **Relocation of power poles:** Power poles currently situated on the landside of the levee toe of some elements would need to be relocated to accommodate proposed seepage berms. To the extent feasible, power poles would be relocated beyond the toe of the new berms outside the maintenance access easement. Should placing poles on top of the seepage berms be required, either raised foundations or steel-reinforced concrete piers would be constructed to prevent the poles from affecting the seepage berms. RD 17 would oversee relocation of the power poles, in coordination with the appropriate utility and construction companies.

- **Site preparation at existing levee sites and in setback levee area:** Site preparation (clearing, grubbing, and stripping) of the levee elements would begin by clearing structures (see discussion in next bullet below) and woody vegetation from the footprint of the proposed improvements and the permanent O&M access and utility corridors. Vegetation would be retained in areas adjacent to but outside of the project footprint. This operation would require removal of some trees and relocation or removal of some elderberry shrubs. Large trees would be felled approximately 3 feet above ground level, with stumps temporarily left in place. Where feasible, small trees and elderberry shrubs would be relocated. Elderberry shrubs would be relocated in accordance with the avoidance and minimization measures outlined for VELB on page 21 of this BA. A minimal amount of belowground disturbance would occur. The clearing operation would be followed by grubbing operations to remove stumps, root balls, and any belowground infrastructure. The area would then be disked to chop surface vegetation and mix it with the near-surface organic soils. The disking operation would be followed by stripping the top 12 inches of earthen material from the landside slope of the existing levee and the footprint of the proposed seepage berms. Excess earthen materials (organic soils, and excavated material that does not meet levee embankment criteria) would be temporarily stockpiled and then respread on the surface of the new levee slopes and seepage berms, provided this material is not contaminated with vegetation. Any stripped material contaminated with vegetation and other debris generated during the clearing and grubbing operations would be hauled off-site to suitable landfills.

- **Removal or modification of landside structures and other facilities:** In a few elements, agricultural facilities (e.g., fences, drainage infrastructure) or parking lots are located within the footprint of the proposed landside levee improvements. These facilities would be removed from or relocated out of the project footprint before levee construction begins in those areas. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Demolished concrete could be sent to a concrete recycling facility. If any wells or septic systems would be affected, they would be abandoned in accordance with the applicable state and county requirements.

- **Construction of the setback levee with seepage berm and underlying cutoff wall:** Construction of the setback levee embankment in Element IVc would begin as soon as sufficient lengths of levee foundation are prepared and weather conditions are suitable. Foundation preparation would include constructing a levee keyway that would be excavated 3–5 feet deep across the entire footprint of the proposed setback levee. A smaller but deeper excavated inspection trench, centered beneath the new waterside hinge point of the setback levee, would then be constructed beneath a small portion of the keyway in accordance with DWR standards. After the foundation layers are backfilled with engineered soil, a geotechnical geogrid fabric would be installed at ground level across the entire setback levee footprint. A second layer of geogrid fabric would be placed at mid-height of the new levee fill section to further reduce the potential for postconstruction settlement of the new levee. The embankment would be constructed of engineered fill, with the fill placed in 3-foot-maximum horizontal lifts by motor graders. Each lift would be moisture-conditioned using water trucks and compacted to the specified density using a suitable compactor, such as a sheep's foot, tamping foot, or rubber-tired roller. Next, quarry stone riprap would be applied in three segments to armor the newly completed setback levee's waterside slope and protect against erosion. Riprap would be placed on the waterside levee above the HTL in areas that are characterized by ruderal land cover (**Exhibit 12**). All waterside woodland would be avoided; all waterside trees would be avoided as well as any tree canopy that overlaps with riprap. Riprap placement will be done either by barge or by long-arm excavator from the top of the levee crown. Riprap dimensions for the three segments are: 340 feet long by 50 feet wide (0.39 acre), 140 feet long by 30 feet wide (0.096 acre), and 230 feet long by 50 feet wide (0.26 acre). A seepage berm would then be constructed on the landside of the setback levee. Fill material for setback levee and seepage berm construction would be obtained from commercial sources and delivered to the levee construction sites using haul trucks.

- **Setback levee site restoration and demobilization:** Upon completion of construction activities, the previously stripped topsoil material would be placed on top of the completed setback levee and associated seepage berms in Element IVc, and any disturbed levee slopes and the tops of the seepage berms would be hydroseeded. An aggregate-base patrol road would be constructed at the landside edge of the seepage berm and setback levees and on the new setback levee crown. The existing levee would be fully restored at the tie-in points to the new setback levee where fill benching was required. The existing levee crown patrol road would be redressed with aggregate base to restore to preconstruction levels. Any disturbed riprap would also be supplemented to ensure a uniform layer across the connection point with the new setback levee. Immediately upon final construction, the setback levee's fill slopes would be covered with erosion control measures until application of the hydroseed. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to preproject conditions. Demobilization would likely occur in various locations as construction proceeds along various elements.

- **Removal of existing levee at setback levee elements, site restoration, and demobilization:** Upon certification of the new setback levee and seepage berm in Element IVc, a 410-linear-foot-long section of the existing outboard levee (which is approximately 2,400 linear feet long in Element IVc) on the downstream side of the existing oxbow would be partially degraded. The area where the levee would be degraded is characterized by ruderal land cover (**Exhibit 12**); some landside vegetation would be removed (as is accounted for in the "Effects – Direct and Indirect Effects on Species in the Action Area" section of this Biological Assessment, but all waterside trees and overlapping tree canopy would be avoided. At least 4.52 acres of riparian vegetation could be established in the area between the new setback levee and the river (**Exhibit 12**). This work would be completed after flood season (in July 1 through November 1) and above the HTL, using primarily scrapers, excavators, and bulldozers to remove the levee section and all present levee encroachments.

- **Construction of seepage berms, seepage berms with chimney drains, and chimney drains within existing seepage berms:** Fill material for levee improvements would be obtained from commercial sources and delivered to the levee construction sites using haul trucks. The material would then be spread by motor graders and compacted by sheep's foot rollers to build new seepage berms and seepage berms with chimney drains. A water truck would be used to properly moisture-condition the soils for compaction. Installing the chimney drains in existing seepage berms would also require the use of an excavator or scraper to remove the existing seepage berm fill material so that the chimney drain fill material could be tied into the drainage rock layer of the existing seepage berm.

- **Construction of cutoff walls:** Cutoff wall construction is anticipated to occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance when necessary. Lights and possibly power generators would be used during nighttime construction hours. Additional equipment would include slurry batch plants to prepare bentonite or bentonite cement mix, pumps, and support vehicles. Four to five batch plants or slurry ponds would be required for the project; these would be located near the site of cutoff wall construction. Each batch plant or slurry pond with associated pumps and support equipment would occupy an area of approximately 100 square feet and would be reclaimed after completion of cutoff wall construction. Cutoff walls may be installed concurrently in two or more different directions within an element. RD 17 proposes to use the deep slurry mix method to install one cutoff wall located at Element VIIe, which would avoid the need to degrade the top of the levee. For the remaining shallow cutoff walls, RD 17 would use conventional slurry trench walls (open-cut method). The number of cutoff wall rig setups would depend on the project schedule and contractor preference. Each deep-slurry-mix cutoff wall rig would move continuously along the proposed alignment to ensure an uninterrupted cutoff wall and to reduce prolonged disturbance to residences near some cutoff wall segments. Each cutoff wall rig can move 50–100 feet horizontally during a 12-hour work shift, while each conventional slurry trench rig can move 75–200 feet horizontally during a 12-hour work shift. Disturbances to residences are expected to be minor because of the limited number of residences near the cutoff wall installation areas. However, where lights, noise, and/or vibration would exceed allowable nighttime standards for the applicable local jurisdiction, work hours would be restricted to daytime work hours.

- **Traffic control during construction:** Traffic control and detours could be required in the immediate vicinity of some levee improvements. Examples of traffic-control measures to be considered if needed are the use of flaggers for one-way traffic control, the use of advance construction signs and other public notices to alert drivers to activity in the area, and the use of "positive guidance" detour signage on alternate access roads to reduce inconvenience to the driving public. Detours for through traffic are not likely to be required.

- **Site restoration and demobilization:** Upon completion of construction activities, previously stripped topsoil material not contaminated with vegetation would be placed on top of the completed seepage berms and any disturbed levee slopes. Any previously nonagricultural, vegetated areas disturbed during construction would be hydroseeded. An aggregate-base patrol road would be constructed at the landside edge of any seepage berms. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to preproject conditions. Demobilization would likely occur in various locations as construction proceeds along various elements.

AVOIDANCE AND MINIMIZATION MEASURES

GENERAL

A qualified biologist, retained by RD 17, would be on-site to ensure compliance with the avoidance and minimization measures described below, particularly where construction activities would occur adjacent to sensitive habitats that would be avoided.

A worker awareness training program would be conducted for construction crews before the start of construction activities. The program would include a brief overview of special-status species and sensitive resources (including riparian habitats) in the Phase 3 Project area, measures to avoid and minimize impacts on those resources, and conditions of relevant regulatory permits.

Further, traffic speeds on unpaved roads would be limited to 15 miles per hour, to reduce dust emissions and to minimize potential effects on listed species, such as the riparian brush rabbit.

VALLEY ELDERBERRY LONGHORN BEETLE

For elderberry shrubs that are located in the Phase 3 Project area, RD 17 would implement the following avoidance and minimization measures that are described in USFWS's *Conservation Guidelines for the Valley Elderberry Longhorn Beetle* (VELB Guidelines), dated July 9, 1999, to avoid and minimize effects on VELB:

- All elderberry shrubs that are located adjacent to construction areas, but can be avoided, would be protected through establishment of a fenced avoidance area. The fencing would be placed at least 20 feet from the dripline of the shrubs. All elderberry shrubs to be protected during construction would be identified and marked by a qualified biologist. Orange construction barrier fencing would be placed at the edge of the respective buffer areas and no construction activities would be permitted within the buffer zone other than those activities necessary to erect the fencing. In cases where the elderberry dripline is less than 20 feet from the work area, k-rails would be placed at the shrub's dripline to provide additional protection to the shrubs from construction equipment and activities. Temporary fences around the elderberry shrubs and k-rails at shrub drip lines would be installed as the first order of work. Buffer area fences around elderberry shrubs would be inspected weekly by a qualified biologist during ground-disturbing activities until adjacent project construction is complete or the fences are removed upon approval by the qualified biologist and resident engineer.

- No insecticides, herbicides, or other chemicals that might harm the beetle or its host plant would be used within 100 feet of elderberry shrubs.

- Elderberry shrubs that require removal would be transplanted to a USFWS-approved site during the dormant period for elderberry shrubs (i.e., November 1 to February 15) and in accordance with the requirements in the VELB Guidelines (USFWS 1999).

- Each elderberry stem measuring 1 inch or greater in diameter at ground level that is adversely affected (i.e., transplanted) would be replaced with elderberry seedlings and seedlings of associated species, in accordance with the VELB Guidelines (USFWS 1999).

Regarding provision for off-site compensatory mitigation for habitat losses, see the "Compensation Measures" section below.

Riparian Brush Rabbit

The following measures would be implemented to avoid and minimize potential adverse effects to riparian brush rabbit in potential habitat within and adjacent to the Phase 3 Project footprint (i.e., Great Valley cottonwood and Great Valley oak riparian forest communities):

- Potential riparian brush rabbit habitat would be identified and avoided wherever possible. The primary engineering and construction contractors would ensure, through coordination with a qualified biologist approved by USFWS and retained by RD 17, that construction would be implemented in a manner that minimizes disturbance of such areas to the extent feasible.
- Temporary fencing would be used during construction to prevent disturbance of potential habitat adjacent to construction areas. Construction personnel, vehicles, and equipment would remain within the identified construction area. In addition, a silt fence or other suitable temporary barrier would be installed around the construction area where it borders suitable habitat for brush rabbits to exclude brush rabbits from the construction site; this silt fence or temporary barrier would either be incorporated into the temporary fencing, or be installed as a separate fence. Temporary signage would be placed along the rabbit exclusion fence at 150-foot intervals, warning contractors to stay within the construction area. The temporary rabbit exclusion fence and associated signage would be inspected by the qualified biologist and construction contractor each morning before the beginning of construction activities, and would be repaired and maintained as necessary. A biological monitor would inspect the fence at least once a week. The temporary rabbit exclusion fence and signage would be removed after construction activities are no longer occurring adjacent to the exclusion area.
- Where suitable habitat for riparian brush rabbit must be removed, vegetation would be removed by hand 2 weeks before construction to ensure that no riparian brush rabbits are present within the construction area at the time of construction. A qualified biologist, retained by RD 17, would be on-site during vegetation removal. Areas of temporary habitat disturbance in the Phase 3 Project area would be revegetated with native plant species and restored to preproject conditions.

Regarding provision for on-site compensatory mitigation for habitat losses, see the “Compensation Measures” section below.

Federally Listed Fish—Delta Smelt, Longfin Smelt, Anadromous Salmonids, and Green Sturgeon

Water Quality

The following measures would be implemented to avoid and minimize potential adverse effects on water quality:

- Any work within the existing floodway (i.e., placing riprap on the waterside levee above the HTL at Element IVc) of the San Joaquin River would not take place during the designated flood season (i.e., November 1 to July 1) and would not begin until evaluation of upstream conditions (e.g., reservoir storage and snowpack) indicated that inundation of these areas would be unlikely to occur during construction.
- RD 17 would comply with all local, state, and federal regulations and environmental requirements regarding turbidity-reduction measures, including the following:
    - obtaining and complying with relevant agency permits (e.g., CDFW streambed alteration agreement, Central Valley Regional Water Quality Control Board [RWQCB] Clean Water Act Section 401 certification, and Section 404 permit);
    - developing and implementing a storm water pollution prevention plan (SWPPP) that identifies specific BMPs to avoid and minimize impacts to water quality during construction activities; and

- complying with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity.

► RD 17 would file a notice of intent with the Central Valley RWQCB to discharge stormwater associated with construction activity. Final design and construction specifications would require the implementation of standard erosion, siltation, and good housekeeping BMPs. Construction contractors would be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for construction activity (Order No. 2009-0009-DWQ). The SWPPP would describe the construction activities to be conducted, BMPs that would be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that would be conducted.

At a minimum, the following specific BMPs are proposed for implementation:

- Conduct all work according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized.
- Install silt fences near riparian areas or existing drainages to control erosion and trap sediment and reseed cleared areas with native vegetation.
- Conduct maintenance on a regular basis to ensure proper installation and function of BMPs, and during storm events, conduct maintenance daily.
- Immediately repair and replace BMPs that have failed (within 48 hours of the event) with sufficient devices and materials (e.g., silt fence, coir rolls, and erosion blankets) provided throughout project construction to enable immediate corrective action for failed BMPs.
- Restrict stockpiling of construction materials (e.g., portable equipment, vehicles, and supplies, including chemicals) to designated construction staging areas, exclusive of any riparian, wetland, or other areas supporting waters.
- Stabilize disturbed soils of construction areas before the onset of the winter rainfall season.
- Stabilize and protect stockpiles from exposure to rain and potential erosion.

The SWPPP also would specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of adverse impacts from use or accidental spills or releases of contaminants. Specific measures applicable to the project would include but would not be limited to the following:

- Require compliance by RD 17 contractors with all applicable State Water Resources Control Board (SWRCB) and Central Valley RWQCB standards and other applicable water quality standards.
- Develop and implement strict on-site handling rules to keep potentially contaminating construction and maintenance materials out of drainages and other waterways.
- When refueling and servicing equipment, use absorbent material or drip pans underneath such equipment to contain spilled fuel, oil, and other fluids; and collect any fluid drained from machinery in leak-proof containers and deliver to an appropriate disposal or recycling facility.
- Maintain controlled construction staging and fueling areas at least 100 feet away from channels or wetlands to minimize accidental spills and runoff of contaminants in stormwater.
- Prevent substances that could be hazardous to aquatic life from contaminating the soil or entering watercourses.

- Maintain spill cleanup equipment in proper working condition. Clean up all spills immediately according to the spill prevention and response plan, which would be prepared by RD 17 or its contractor or representative and approved by the RWQCB prior to commencement of project ground-breaking.
- Immediately (within 24 hours) notify NMFS, USFWS, CDFW, and the Central Valley RWQCB of any reportable spills and cleanup occurrences. Record all such spills, and the success of the efforts to clean them, in postconstruction compliance reports.
- Develop a slurry spill contingency plan, which would be prepared by RD 17 or its contractor or representative before commencement of project groundbreaking, to respond to a potential for bentonite slurry spill and prevent slurry from entering watercourses.
- Store and transport construction materials handled by RD 17 or its contractors in a manner that minimizes potential water quality impacts. Locate storage areas away from drainages and waterways, outside the floodplain, and away from sensitive resources, and make use of containment facilities.

BMPs would be applied to meet the "maximum extent practicable" and "best conventional technology/best available technology" requirements and address compliance with water quality standards. RD 17 would implement a monitoring program that would be implemented during and after construction to ensure that the Phase 3 Project would comply with all applicable standards and that the BMPs would be effective.

COMPENSATION MEASURES

VALLEY ELDERBERRY LONGHORN BEETLE

As described above under "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle," compensation for effects on VELB would be provided in accordance with the VELB Guidelines (USFWS 1999). Elderberry shrubs that cannot be avoided would be transplanted to a USFWS-approved site and VELB habitat conservation credits would be purchased from a USFWS-approved VELB habitat conservation bank. RD 17 would purchase a comparable amount of VELB habitat conservation credits from the French Camp Conservation Bank to offset the adverse effects of transplanting elderberry shrubs. Purchasing VELB habitat credits at a USFWS-approved habitat conservation bank would fully compensate for the loss of VELB habitat resulting from construction activities associated with the Phase 3 Project.

RIPARIAN BRUSH RABBIT

Compensation for effects on riparian brush rabbit habitat would consist of restoring natural habitats in the Phase 3 Project area, and preserving and/or restoring natural habitats in the project vicinity.

On-site compensation for adverse effects on riparian brush rabbit habitat would include restoration of riparian habitat in the proposed setback levee area in Element IVc. Once the new setback levee is constructed and certified in Element IVc, a small section of the existing levee would then be partially degraded. Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4.52 acres of ruderal grassland that can be restored as riparian habitat (**Exhibit 12**). The restored riparian habitat would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a small notch along the north side, the existing levee would remain in place, thus providing upland refugia for the species during high-water events. The 4.52-acre area would be contiguous with existing waterside riparian habitat along Element IVc; this waterside riparian habitat along Element IVc extends northward through Elements IVa, IIIa, and IIIb, and southward through Elements Va and VIa.1. There are documented occurrences of riparian brush rabbit in the waterside riparian habitat in Elements IIIa and IIIb, north of Element IIIa and south of Element VIa.1; therefore, reestablishing and protecting riparian habitat in Element IVc would provide expanded and connected habitat for this species.

RD 17 is also evaluating options for providing off-site compensatory habitat to offset effects of the Phase 3 Project on riparian brush rabbit. Additional off-site compensatory habitats would include preserving existing waterside riparian habitats and/or restoring natural riparian habitats. These options would be evaluated in coordination with USFWS during the Section 7 consultation.

MITIGATION AND MONITORING PLAN

A mitigation and monitoring plan would be prepared in coordination with USFWS, NMFS, USACE, and CDFW to guide RD 17 and its partners as they establish and manage the proposed action's compensation. The mitigation and monitoring plan would address the habitat restoration in Element IVc and off-site compensatory habitat components. This plan would:

- describe specifications for the restoration of habitat components, including details about the restoration of riparian habitats, with a list of the species and drawings/designs to show the location of the species and planting density;
- establish specific success criteria for the habitat components, including:
  - performance standards to determine whether the habitat improvement was trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions);
  - monitoring and maintenance protocols; and
  - measureable goals to ensure vegetation survival to provide and replace riparian habitats;
- specify remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring); and
- describe short- and long-term management and maintenance of the habitat lands.

The plan will be included in the Final Environmental Impact Statement and Final Environmental Impact Report and reviewed and approved by USFWS and NMFS before groundbreaking in portions of the Phase 3 Project area that could affect the species addressed in this BA. RD 17 would provide for the conservation of the restored riparian habitat in the setback levee area within Element IVc and for off-site habitat compensation. The compensation habitat would ultimately be transferred to a suitable land management organization for long-term management and monitoring.

This habitat creation and enhancement would fully compensate for the loss of habitat for riparian brush rabbit resulting from construction activities associated with the Phase 3 Project.

ACTION AREA

The action area is defined here in accordance with ESA guidelines as “all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action” (50 Code of Federal Regulations [CFR] 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Project. Areas downstream of the Phase 3 Project area might also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions. The extent of this potential effect is difficult to quantify. However, the inclusion of waterways within 15 river miles of the project site would likely exceed the areas affected by the improvements.

ENVIRONMENTAL BASELINE

HYDROLOGY

SACRAMENTO–SAN JOAQUIN DELTA

The Delta extends inland from the confluence of the Sacramento and San Joaquin Rivers west of Antioch to Sacramento on the Sacramento River and to near Mossdale on the San Joaquin River. The Phase 3 Project area is in the southeastern portion of the Delta, within the legal boundary of the Delta as defined by Section 12220 of the California Water Code.

The legal Delta encompasses an area of approximately 851,000 acres (of which approximately 135,000 acres consist of waterway, marshland, or other water surfaces). The Delta is divided into a Primary Zone and a Secondary Zone, as defined by the Delta Protection Act of 1992. Land uses in the Primary Zone are regulated to protect the area for agriculture, wildlife habitat, and recreational uses. The Secondary Zone is the area outside the Primary Zone and within the legal Delta. Where urban development activities occur in the Secondary Zone, efforts should be taken to ensure that these activities do not adversely affect Delta waters, Primary Zone habitat, or recreational uses. The San Joaquin River delineates the boundary between the Primary Zone to the west and the Secondary Zone to the east. Accordingly, the Phase 3 Project is located in the Secondary Zone.

The Sacramento River contributes roughly 75–80% of the Delta inflow in most years and the San Joaquin River contributes about 10–15%; the Mokelumne, Cosumnes, and Calaveras Rivers, which flow into the eastern side of the Delta, contribute the remainder. The rivers flow through the Delta and into Suisun Bay, San Pablo Bay, San Francisco Bay, and the Pacific Ocean. Historical annual Delta inflow averaged approximately 23 million acre-feet (MAF) between 1945 and 1995, with a minimum inflow of approximately 6 MAF in 1977 and a maximum of approximately 70 MAF in 1983. Water flowing into the Delta is used for urban and agricultural use, recreation, navigation, and wildlife and fisheries. The Delta provides drinking water for about 23 million Californians.

Freshwater inflows to the Delta vary greatly, depending on precipitation, snowmelt, and Central Valley Project (CVP) and State Water Project (SWP) water operations. During the summer months, most inflow to the Delta comes from regulated releases from SWP and CVP reservoirs. Both projects also withdraw large volumes of water from the Delta for agricultural and urban use. Precipitation in the project region occurs primarily during the months of November through March, with the average annual precipitation ranging from about 8 inches near Tracy to approximately 17 inches near Lodi. Near Lathrop, the annual precipitation is approximately 12 inches.

Water movement in the Delta responds to five primary forcing mechanisms:

- freshwater inflows to the ocean;
- Delta exports and upstream diversions;
- operation of water control facilities such as dams, export pumps, and flow barriers; and
- the regular tidal movement of seawater into and out of the Delta.

In addition, winds and salinity behavior in the Delta can generate secondary currents that, despite being of low velocity, can be of considerable significance with respect to transporting contaminants and mixing different sources of water. Changes in flow patterns in the Delta, whether caused by export pumping, winds, atmospheric pressure, flow barriers, tidal variations, inflows, or local diversions, can influence water quality at drinking water intakes.

The Delta is a hydrologically complex region of interlacing channels, marshland, and islands. The Delta has been reclaimed into more than 60 islands and tracts, interlaced with about 700 miles of waterways. Some channels are edged with aquatic and riparian vegetation, but most are bordered by steep banks of earth or riprapped levees. Vegetation is generally removed from channel margins to increase flood flow capacity and facilitate levee maintenance. About 520,000 acres are devoted to farming. An approximately 1,100-mile network of levees protects the reclaimed land, most of which lies near or below sea level, from flooding. Some of the island interiors are as much as 25 feet below sea level.

Nearly 16.5 miles of the 19 miles of levees protecting RD 17 are considered federal project levees; the 2.6-mile dryland levee is not a federal levee. Federal project levees were either constructed by the federal government (typically through USACE) or built by others and later brought under federal jurisdiction.

San Joaquin River

The San Joaquin River originates in the Sierra Nevada and enters the San Joaquin Valley at Friant Dam. Most of the flow in the lower San Joaquin River is derived from inflow from the Merced, Tuolumne, and Stanislaus Rivers (Northeastern San Joaquin County Groundwater Banking Authority 2004). The 330-mile-long San Joaquin River, which drains a watershed area of 13,540 square miles from the Sierra Nevada to the Delta, contributes approximately 15% of the inflow to the Delta (Delta Protection Commission 2000). Flowing through portions of Fresno, Madera, Merced, Stanislaus, San Joaquin, Sacramento, and Contra Costa Counties, the river has flows ranging from 1,500 cubic feet per second (cfs) in dry years to more than 40,000 cfs in wet years (Friant Water Users Authority and Natural Resources Defense Council 2002).

Hydrologic conditions in the San Joaquin River basin are dominated by snowmelt from the Sierra Nevada. Before major water storage projects were completed on the San Joaquin River and its major tributaries, lower San Joaquin River flows generally peaked in late spring/early summer and dropped to low levels in the fall. Since the completion of Friant Dam (1944), McClure Reservoir (1967 on the Merced River), Don Pedro Reservoir (1971 on the Tuolumne River), and New Melones Reservoir (1979 on the Stanislaus River), the lower San Joaquin River's seasonal flow pattern has changed substantially. Before 1944, based on 1923–1944 records, flow in the lower San Joaquin River tended to peak in May and June, with an average monthly flow of almost 11,000 cfs, and declined rapidly to an average monthly flow of approximately 1,200–1,300 cfs in August and September. Since 1979, the average monthly flow has peaked in March at just over 10,000 cfs, with a more gradual decline to approximately 2,400 cfs in August. In addition, the San Joaquin River is tidally influenced from the Delta and the San Francisco Bay. Tidal fluctuation in the San Joaquin River has been modeled to approximately the Vernalis tide gauge and the Airport Way crossing of the San Joaquin River, which is approximately 13 river miles upstream of the project site.

The SJRRP was established in late 2006 to implement the Stipulation of Settlement in *NRDC et al. v. Kirk Rodgers et al*. (Settlement). Authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act, included in Public Law 111-11. The goal of the SJRRP is to reoperate and increase the release of water from Friant Dam in accordance with the Settlement, and in a manner consistent with federal, state, and local laws, and future agreements with downstream agencies, entities, and landowners (Reclamation and DWR 2011). The Settlement establishes two primary goals:

- *Restoration Goal*—To restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish. To achieve the Restoration Goal, the Settlement calls for releases of water from Friant Dam to the confluence of the Merced River (referred to as Interim and Restoration Flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon.

- *Water Management Goal*—To reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim and Restoration Flows provided for in the Settlement. To achieve the Water Management Goal, the Settlement calls for recirculation, recapture, reuse, exchange, or transfer of the Interim and Restoration Flows to reduce or avoid impacts on water deliveries to all of the Friant Division long-term contractors caused by the Interim and Restoration Flows.

The SJRRP would release Interim and Restoration Flows to the San Joaquin River from Friant Dam in accordance with the flow schedule presented in Exhibit B of the Settlement. The Settlement establishes the Recovered Water Account and recovered-water program, which make water available to all Friant Division long-term contractors who provide water to meet Interim or Restoration Flows so that the impacts of Interim and Restoration Flows on such contractors can be reduced or avoided.

Local Drainage

Stormwater runoff in the RD 17 area is commonly collected in agricultural ditches, channels, municipal stormwater sewers, or human-made ponds before being pumped to the San Joaquin River. Runoff from the area east of the San Joaquin River, along levee Elements Ie and VIIb, is directed west through agricultural swales and ditches, and then pumped into the river by means of private agricultural pumps. Runoff from developed lands adjacent to Elements IVa, IVc, and VIa.4 is directed to the City of Lathrop's storm drainage system, held in detention basins, and ultimately pumped into the San Joaquin River through a municipal stormwater outfall. Runoff in the area around Element VIIe, which encompasses the Oakwood Lake development, first flows into the artificial lake in the center of the development, then is pumped into the river if lake levels become too high.

WATER QUALITY

Surface Water Quality

Water quality in the Delta and portions of the San Joaquin River are heavily influenced by CVP and SWP operations. Generally, Delta water quality is best during the winter and spring months and poorer during the irrigation season and early fall. Water quality in the San Joaquin River is influenced by factors such as rain and snowmelt runoff, reservoir operations, and irrigation return flows in the San Joaquin River basin. Agricultural return flows commonly discharge elevated salt loads into the San Joaquin River. The SWRCB has set flow and water quality objectives at Vernalis, located just upstream of the Phase 3 Project area. To meet the Vernalis objective, the U.S. Bureau of Reclamation supplements flows on the San Joaquin River with releases from New Melones Reservoir on the Stanislaus River (Northeastern San Joaquin County Groundwater Banking Authority 2004).

The latest version of the Section 303(d) list for California issued by the SWRCB (approved October 26, 2006) identifies an impaired status for waterways in the eastern Delta, including the lower San Joaquin River. Potential sources of pollution for all of the listed constituents in the basin include agriculture, urban runoff/storm sewers, resource extraction, and unknown sources. The eastern Delta, including the lower San Joaquin River, is on the Section 303(d) list for impairment from boron, chlorpyrifos, diazinon, dichlorodiphenyltrichloroethane (DDT), electrical conductivity, unknown toxicity, Group A pesticides, exotic species, and mercury. Downstream of the Phase 3 Project area, the Stockton Deep Water Ship Channel is being addressed by a total maximum daily load (TMDL) plan for dissolved oxygen and is no longer on the Section 303(d) list. TMDLs have been initiated for organophosphorus pesticides (i.e., diazinon and chlorpyrifos), salinity and boron, and selenium in the lower San Joaquin River watershed and for total dissolved solids and mercury in Delta channels. TMDLs for the other listed pollutants are scheduled to be developed at various times over the next 10 years, in accordance with the priorities contained in the Section 303(d) list.

Major monitoring programs in the San Joaquin River include DWR's Municipal Water Quality Investigations Program and Water Rights Decision 1485 Water Quality Monitoring Program. The City of Stockton also monitors ambient water quality to assess potential effects of discharges from the Stockton Regional Wastewater Control Facility. Data are collected at five water quality monitoring sites along the San Joaquin River near the Phase 3 Project area. The Mossdale Bridge sampling site at the Interstate 5 crossing over the San Joaquin River is near Elements VIcde and VIIb. The Vernalis sampling site is located near the town of Vernalis, just upstream of the Phase 3 Project area. Some of the broad categories that are monitored are discussed briefly below.

HABITAT

Dense riparian forests once flanked the San Joaquin River in this area. In contrast, the habitat today consists of linear areas and occasional remnant patches of riparian forests and related riparian scrub that grow on or adjacent to the levee, primarily on the waterside. A few larger areas of these riparian forests are present where the river turns away from the levee and creates a point bar and an upland floodplain area. Riprap or large boulders cover the lower half of most of the waterside of the San Joaquin River east levee in the Phase 3 Project area, and ruderal vegetation grows in open areas, especially upslope of the riprap and on large open areas on the landside of the levee. Other areas of levee on the waterside are barren and/or covered with stumps and dead vegetation, likely as a result of levee maintenance that has included cutting scrub and low vegetation, burning, and applying herbicide. Some of the lands on the waterside of the levee are privately held and are affected by grazing and other landowner activities.

The landside reaches of the Phase 3 Project area levees are primarily barren or covered with ruderal vegetation. Beyond the base of the levees, riparian vegetation is rare but occasionally present in small, isolated patches. Other trees include occasional single or isolated stands of native oaks and nonnative trees that have been planted around farms, agricultural fields, and residential or other types of development. Habitat and land cover types present in the Phase 3 Project area include riparian forests, nonnative woodlands, agricultural lands, ruderal and developed areas, and aquatic features (including marsh, wetlands, and ponds) (**Exhibits 13a** through **13d**).

VEGETATION AND LAND COVER

As described below, terrestrial vegetation and land cover types in the Phase 3 Project area and vicinity include Great Valley cottonwood riparian forest (remnant), Great Valley oak riparian forest (remnant), nonnative woodland, agricultural (row crops, orchards, dirt roads, and irrigation ditches), and ruderal and developed (residential housing, parks, boat launch facilities, and roads).

- **Great Valley cottonwood riparian forest:** Remnant patches of Great Valley cottonwood riparian forest within the Phase 3 Project area are dominated by large Fremont cottonwood (*Populus fremontii*) trees and Goodding's willow (*Salix gooddingiii*). Most of the otherwise linear or smaller patchy areas of this community lack Fremont cottonwood and are represented by Goodding's willow, red willow (*S. laevigata*), arroyo willow (*S. lasiolepis*), narrow leaved-willow (*S. exigua*), scattered valley oak (*Quercus lobata*), Oregon ash (*Fraxinus* latifolia), and buttonbush (*Cephalanthus occidentalis*). Native ground cover species, found mainly in the larger remnant patches of riparian forest, include California blackberry (*Rubus ursinus*) and wild rose (*Rosa californica*). Common nonnative understory species found in most elements include Himalayan blackberry (*Rubus discolor*) and tree tobacco (*Nicotina glauca*). Most of the Great Valley cottonwood riparian forest community could also be characterized as Great Valley riparian scrub, which does not include Fremont cottonwood and is characterized by a shorter canopy and more uniform structure. This habitat, however, is part of the Great Valley cottonwood riparian forest that was extensive and connected along this entire reach of the San Joaquin River. Therefore, this BA describes all riparian habitat as such. The largest stands of Fremont cottonwood trees in the Phase 3 Project area are present in Elements IIIb, IVc, Va, and VIa.1.
- **Great Valley oak riparian forest:** Great Valley oak riparian forest is located within the Phase 3 Project area, occurring only on the landside of the levees. This is a medium to tall (rarely to 100 feet) broadleaved, winter deciduous, closed-canopy riparian forest dominated by valley oak. Understories include scattered Northern

California black walnut (*Juglans nigra*) and western sycamore (*Platanus racemosa*) as well as young valley oaks. Understory plants include California rose (*Rosa californica*), blackberry (*Rubus* spp.), and western poison oak (*Toxicodendron diversilobum*) (Hickman 1993; Holland 1986). Two significant oak groves of very large, healthy valley oak trees are present on the landside of Elements IIIb and IVa and account for most of the Great Valley oak riparian forest. Several groups of smaller valley oak trees and individual valley oaks scattered along the landside of other Phase 3 Project elements also contribute to this community.

- **Nonnative woodland:** Along the landside of Elements Ie, VIa.1, VIde, and VIIg, nonnative trees have been planted around farms, agricultural fields, and residential or other types of development. These woodlands lack understory vegetation, other than grasses and ruderal vegetation.

- **Agricultural cropland:** Cropland in the Phase 3 Project area is dominated by alfalfa fields, orchards, and row crops, such as tomatoes. Ruderal species grow along the edges of fields and irrigation ditches, some of which contain water and associated aquatic plants. The largest areas of agricultural lands are present in Elements Va and VIa.1, and Element VIcde.

- **Ruderal vegetation:** Ruderal vegetation is characterized by nonnative weedy and sometimes invasive vegetation and nonnative annual grasses. Common weed species include yellow star-thistle (*Centaurea solstitialis*), black mustard (*Brassica nigra*), shortpod mustard (*Hirschfeldia incana*), Italian thistle (*Carduus pycnocephalus*), milk thistle (*Silybum marianum*), and Himalayan blackberry. Common grass species include ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum* ssp. *leporinum*), Bermuda grass (*Cynodon dactylon*), and Johnsongrass (*Sorghum halepense*). The levee slopes are dominated by ruderal vegetation. Large open areas in Elements IIIa and IVc are also composed primarily of ruderal vegetation, as are smaller open areas in Elements VIcde and VIIe that border roads, parking lots, and agricultural land.

- **Developed areas:** Developed areas in the Phase 3 Project area consist of residential areas bordering Elements IVa, IVc, Va and VIa.1, and VIIe; parks located in Elements IVc and VIa.2, the latter of which is also a boat launching facility; and ranch houses and related facilities located in or adjacent to Elements Ie, IIab, Va and VIa.1, and dryland levee Element XI. Vegetation in residential areas and parks consists of turf grasses, landscape trees, and occasional valley oak trees. Ranch lands often contain English walnut trees (*Juglans regia*), a variety of landscaped trees, and occasional native valley oak trees.

AQUATIC HABITATS

The principal surface water bodies associated with the Phase 3 Project area are the San Joaquin River and Walthall Slough. Project Elements Ia through IVc are located downstream of the confluence of the San Joaquin River and Old River. Element V is located directly adjacent to this confluence. Elements VIa.1 through VIIe are upstream of the confluence of the San Joaquin River and Old River. Small portions of Elements VIIe and VIIg are located along Walthall Slough. An approximately 3.5-acre constructed pond is located adjacent to Element IIab, but outside of the project footprint (**Exhibit 13a**).

In the Phase 3 Project area, the San Joaquin River is characterized as a wide channel (approximately 300 feet) with little riparian canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. Altered flow regimes, flood risk management, and bank protection efforts along much of the San Joaquin River have reduced riparian vegetation and associated shaded riverine aquatic (SRA) habitat, sediment transport, channel migration and avulsion, and large woody debris recruitment, and have isolated the channel from its floodplain. This has resulted in a decline in habitat quality for fish species using the San Joaquin River near the Phase 3 Project area. However, fish use this segment of the river, even if only as a migratory pathway to and from upstream spawning and rearing areas.

Wetland vegetation in the Phase 3 Project area is limited to coastal and valley freshwater marshes, several agricultural ditches, and the edges of one constructed pond. Freshwater marsh is isolated in a depression on the landside of the levee in Element 1b between Howard Road to the north and a dirt farm road on the south. A limited amount of freshwater marsh also is present around the edges of a constructed pond, located on a large private estate and equestrian center that is east of the Phase 3 Project area levee in Element IIab. A second area of freshwater marsh is located just outside of the Phase 3 Project area in Element Va, and in an area of backwater on the San Joaquin River. Agricultural ditches are located along the edges of fields and orchards.

FISH POPULATIONS

The lower San Joaquin River and Delta serve as a migration corridor and/or provide other types of habitat (e.g., rearing, spawning) for steelhead, delta smelt, white sturgeon (*Acipenser transmontanus*), and green sturgeon. Numerous other resident native and nonnative species are also found in the San Joaquin River. Among the native species present in the river are blackfish (*Orthodon microlepidotus*), threespine stickleback (*Gasterosteus aculeatus*), and San Joaquin roach (*Lavinia symmetricus* sp.); while nonnative species include striped bass (*Morone saxatilis*), white catfish (*Ameiurus catus*), and bluegill (*Lepomis macrochirus*). In late-2014, experimental populations of spring-run Chinook salmon will be reintroduced to the San Joaquin River, as a component of the SJRRP (see "San Joaquin River" subsection above).

The small, unnamed pond in Element IIab (**Exhibit 13a**) may contain fish and other aquatic species. Given its isolated nature and size, this pond likely supports only nonnative warm-water fish that probably have been introduced. Typical fish that are found in similar ponds include bluegill, western mosquitofish (*Gambusia affinis*), and catfish (*Ameiurus* or *Ictalurus* spp.), among other nonnative warm-water species.

WILDLIFE

Common wildlife species expected in the Phase 3 Project area are those typically associated with agriculture (alfalfa, row crops, and orchards) and ruderal habitat, which account for 57% of the Phase 3 Project area's footprint. Species include California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), western harvest mouse (*Reithrodontomys megalotis*), and California meadow vole (*Microtus californicus*). These small mammals are prey for a variety of raptor species known to occur in the area, including Swainson's hawk (*Buteo swainsoni*). Riparian habitats in the Phase 3 Project area provide nesting habitat for a wide variety of bird species.

SPECIES ACCOUNTS

This section presents species accounts for the federally listed species considered in this BA, including relevant life history and habitat use, as well as the species' potential for occurrence in the action area. The action area (see the "Action Area" section above) encompasses the entire area that may be affected by the Phase 3 Project, including more distant locations where indirect effects might occur. However, the species accounts below focus on the habitat present in the Phase 3 Project area itself and describe the potential for federally listed species to occur in the general vicinity. Only when the habitat quality or species distribution is specifically known for the action area is it described.

VALLEY ELDERBERRY LONGHORN BEETLE

VELB has four life stages: egg, larva, pupa, and adult. This species, which is federally listed as threatened, is nearly always found on or close to its host plant, the elderberry (*Sambucus* sp.). Females lay their eggs on the bark, and larvae hatch and burrow into the stems. The larval stage can last 2 years, after which the larvae enter the pupal stage and transform into adults. Adults are active (feeding and mating) from March to June (USFWS 2006). It appears that to function as VELB habitat, host elderberry shrubs must have stems that are 1.0 inch or greater in diameter at ground level. Use of the plants by the beetle is rarely apparent. Frequently, the only exterior evidence of the shrub's use by the beetle is an oval exit hole created by the larva just before the pupal stage. Field studies conducted along the Cosumnes River and in the Folsom Lake area suggest that larval galleries can be found in elderberry stems with no evidence of exit holes, because the larvae either succumb before constructing an exit hole or are not far enough along in the developmental process to construct an exit hole (USFWS 1996a).

VELB is patchily distributed throughout the remaining riparian forests of the Central Valley from Redding to Bakersfield, and appears to be only locally common (i.e., found in population clusters that are not evenly distributed across the Central Valley). Extensive loss of Central Valley riparian forests has occurred since 1900, with riparian forests declining by 80–96% depending on the region (USFWS 2006). Although it is wide-ranging, VELB is thought to have suffered a long-term decline because of human activities that have caused widespread alteration and fragmentation of riparian habitats and, to a lesser extent, upland habitats that support the beetle. Low density and limited dispersal capability may cause the beetle to be particularly vulnerable to population isolation as a result of habitat fragmentation. Insecticide and herbicide use in agricultural areas and along road rights-of-way may be factors limiting the beetle's distribution. The age and quality of individual elderberry shrubs/trees and stands as a food plant for beetle may be a factor in its limited distribution.

Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than one inch in diameter at ground level; therefore, it is not considered suitable VELB habitat. See **Exhibit 14** for locations of the elderberry shrubs that were observed within 100 feet of the Phase 3 Project area during field surveys in 2014.

CRITICAL HABITAT

Critical habitat for VELB was designated at the time of listing. Two areas along the American River in the Sacramento metropolitan area were designated as critical habitat for this species. The Phase 3 Project area is not located within designated critical habitat for VELB.

RECOVERY PLAN FOR VALLEY ELDERBERRY LONGHORN BEETLE

The *Recovery Plan for Valley Elderberry Longhorn Beetle* (USFWS 1984) lacks specific goals and does not include objective, measurable recovery criteria (USFWS 2006). The recovery plan identified additional essential habitat for this species in an area along Putah Creek, Solano County, and an area along the American River Parkway, Sacramento County. USFWS released a 5-year status review for VELB on October 2, 2006 (USFWS 2006). This review reported an increase in known beetle locations, from 10 at the time of listing in 1980 to 190 in 2006. Because of the presumed increase in the estimated population and the concurrent protection and restoration of several thousand acres of riparian habitat suitable for VELB, USFWS's status review determined that this species is no longer in danger of extinction and recommended that the species no longer be listed under the ESA. On October 2, 2012, the USFWS issued a proposed rule to delist VELB (78 FR 66058); however, on September 17, 2014, the USFWS withdrew this proposal, stating that the scientific information and analysis relied upon in the October 2012 proposed was not strong enough to support a decision to delist the species (79 FR 55874).

RIPARIAN BRUSH RABBIT

Riparian brush rabbits, which are federally listed as endangered, inhabit riparian communities in the northern San Joaquin Valley that are dominated by thickets of willows and large clumps of shrubs and vines such as wild rose, blackberries, coyote bush, and wild grape. Historically, riparian brush rabbits inhabited dense, brushy areas of valley riparian forests, marked by extensive thickets of wild rose, blackberries, and willows (Sandoval et al. 2006).

Suitable habitat for riparian brush rabbits is characterized by an abundance of woody ground litter, mats of low-growing vines and shrubs, and areas of higher ground not subject to regular or heavy flooding (Sandoval et al. 2006). On a seasonal basis, they also may use dense, tall stands of herbaceous plants adjacent to patches of riparian shrubs (Williams and Hamilton 2002). They tend to avoid large openings in the understory cover, frequenting only small clearings in the vegetation while foraging (USFWS 1998). An essential component of habitat for riparian brush rabbits is high-ground refugia from flooding, which provide protection from predators and dry habitat during prolonged rainstorms (USFWS 1998).

The only known populations of riparian brush rabbits are confined to Caswell Memorial State Park on the Stanislaus River in Stanislaus County, approximately 10 miles southeast of the Phase 3 Project area, and in the south Delta along the San Joaquin River and overflow channels (Williams and Hamilton 2002; Williams et al. 2002; Lloyd and Williams 2003; Vincent-Williams et al. 2004; CNDDB 2014) (**Exhibit 15**). The population in the south Delta is found in Paradise Cut along the rights-of-way of the two railroads that cross Paradise Cut and Tom Paine Slough, and in an oxbow on the San Joaquin River near Mossdale Landing (CNDDB 2014). Riparian brush rabbits have also been found along the San Joaquin River north of the oxbow population, in waterside riparian habitat near the Phase 3 Project area adjacent to Elements IIIa and IIIb, between Elements IIab and IIIa, and between Elements VIa.1, and VIa.4 (CNDDB 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004) (**Exhibit 15**). Other historical habitats along the San Joaquin River and tributaries are believed to no longer be suitable for riparian brush rabbits because of irrigated agriculture, livestock grazing, and impoundment and channelization of streams. High-ground refugia also may be lacking in these areas (Williams and Hamilton 2002).

In Paradise Cut, existing habitat for riparian brush rabbits is confined to levee bases, the channel banks of Paradise Cut, and pockets of low ground along the bottom of Paradise Cut. Generally, areas of suitable habitat in these locations are very narrow (15–100 feet wide). Most of the channels in Paradise Cut are in effect dead-end sloughs fed by Old River, with large portions containing water year round, which results in the isolation of some upland areas (i.e., islands). The existing habitat for rabbits is covered in water on average once every 4 years, when flood flows in the San Joaquin River are sufficient to overtop the Paradise Weir. Brush rabbits probably use the UPRR right-of-way as high-water refugia during flooding events (Williams and Hamilton 2002).

Occupied habitat for riparian brush rabbit is documented adjacent to the Phase 3 Project area along the waterside levee in Elements IIIa and IIIb, between Elements IIab and IIIa, and between Elements VIa.1, and VIa.4. The waterside habitat along Elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The waterside habitat between Elements IIab and IIIa is dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The waterside habitat between Elements VIa.1 and VIa.4 is on an oxbow with dense riparian vegetation. Other patches of riparian vegetation along the San Joaquin River and adjacent to Phase 3 Project area levees, such as the Great Valley cottonwood forest and Great Valley oak riparian forest communities depicted in **Exhibits 12a** through **12d**, provide potentially suitable habitat for riparian brush rabbit, including the small areas of riparian habitat that are present on the waterside of Phase 3 Project area Elements IIab, IVc, and Va.

Riparian brush rabbits forage along the edges of shrub cover and in small clearings in the vegetation cover rather than in large openings. They feed on herbaceous vegetation such as grasses, sedges, clover, forbs, and buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). This species has a small home range and mainly remains hidden under protective shrub cover, seldom venturing more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006). North of Element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., Elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.

CRITICAL HABITAT

Critical habitat has not been designated for riparian brush rabbit.

RECOVERY PLAN FOR RIPARIAN BRUSH RABBIT

The *Recovery Plan for Upland Species of the San Joaquin Valley, California* addresses the riparian brush rabbit (USFWS 1998). At the time the recovery plan was prepared, only the Caswell Memorial State Park population was known to exist. One of the most important conservation actions identified in the plan was establishment of other viable populations within the park's range. The recovery plan recommended the following actions (USFWS 1998):

- Initiate a reintroduction program that includes researching genetic diversity among remaining individuals.
- Implement a captive breeding program to translocate individuals to new populations.
- Establish at least three additional wild populations in the San Joaquin Valley in restored and expanded suitable habitat within the rabbit's historical range.

In 1999, the Endangered Species Recovery Program began implementing the *Controlled Propagation and Reintroduction Plan for the Riparian Brush Rabbit* (Williams et al. 2002), which was recommended in the *Recovery Plan for Upland Species of the San Joaquin Valley, California* (USFWS 1998). The primary goal of the program is to prevent extinction by providing animals for reintroduction to establish new populations or augment existing populations. In July 2002, captive-bred rabbits were released at the San Luis National Wildlife Refuge, near Los Banos in the central San Joaquin Valley, and in 2005, a population of captive-bred rabbits was introduced to a private ranch along the San Joaquin River in Stanislaus County, adjacent to the San Joaquin River National Wildlife Refuge (USFWS 2007). This effort is ongoing.

DELTA SMELT

Delta smelt were formally listed as threatened under the ESA on March 5, 1993 (59 FR 440). On December 19, 1994 (59 FR 65256), USWFS designated critical habitat. Delta smelt are found only from Suisun Bay upstream through the Sacramento–San Joaquin estuary in Contra Costa, Sacramento, San Joaquin, Solano, and Yolo Counties.

Delta smelt are endemic to the upper Sacramento–San Joaquin River estuary and occur primarily in open surface waters of Suisun Bay, in the Sacramento River downstream of Isleton, and in the San Joaquin River downstream of Mossdale (Bennett 2005), including the Project site. Their historic range is thought to have extended from Suisun Bay upstream to at least the city of Sacramento on the Sacramento River and Mossdale on the San Joaquin River. They used to be one of the most common pelagic fish (fish living in open water away from the bottom) in the upper Sacramento–San Joaquin estuary (USFWS 2004). The delta smelt population generally is concentrated in the estuary west of the confluence of the Sacramento and San Joaquin Rivers in high-outflow years and in the north Delta in low-outflow years (Sweetnam 1997, 1998; Bennett 2005). Delta outflow determines the location of the salinity gradient and may strongly influence delta smelt distribution. USFWS data indicate that delta smelt are found in the San Francisco Bay/Sacramento–San Joaquin Delta (Bay-Delta) estuary where salinity is generally less than 2 parts per thousand. Except when spawning in freshwater, delta smelt are most frequently caught in or are slightly upstream of the entrapment zone (Bennett 2005). In the CDFW delta-wide 20mm delta smelt survey, delta smelt larvae have been observed only occasionally and in very low abundance in the vicinity of the project site (less than 4 larvae in 10,000 cubic meters sampled on April 4, 2014).

CRITICAL HABITAT

Although the Phase 3 Project area is near the upper limit of the known distribution of delta smelt, it is included in the area designated as critical habitat for the species (Critical Habitat Determination for the Delta Smelt, 59 FR 65256, December 19, 1994). In the critical-habitat designation, USFWS identified the following primary constituent elements essential to conservation of delta smelt: physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration (59 FR 65256). The primary constituent elements are organized by habitat conditions required for each life stage. USFWS has identified specific areas in the Delta for spawning habitat, larval and juvenile transport, and adult migration for delta smelt. The Phase 3 Project area and larger action area include places identified for larval and juvenile transport and adult mitigation, but do not include specific areas important for delta smelt spawning habitat (59 FR 65256).

RECOVERY PLAN FOR DELTA SMELT

The *Sacramento–San Joaquin Delta Native Fishes Recovery Plan* includes the restoration of abundance and distribution of delta smelt (USFWS 1996b). Action items in the recovery plan for delta smelt refer to four zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of delta smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Project area or action area.

LONGFIN SMELT

On April 2, 2012, the USFWS issued its finding that the longfin smelt warranted protection under the ESA, and added it as a candidate species for protection under the ESA (77 FR 19755). Longfin smelt are found in California's bay, estuarine, and nearshore coastal environments from San Francisco Bay north to Lake Earl near the Oregon border. The southernmost detection of the species was a single fish from Monterey Bay (Eschmeyer et al. 1983), although spawning has not been documented south of San Francisco Bay. The San Francisco estuary and the Delta support the largest longfin smelt population in California. Longfin smelt are more broadly distributed throughout the Bay-Delta estuary and are found in water with higher salinities than delta smelt. Longfin smelt are most often concentrated in Suisun and San Pablo Bays and north San Francisco Bay during nonspawning periods (Moyle 2002). No fish surveys have been conducted by RD 17 within the river stretch adjacent to the Phase 3 Project area; however, CDFW's delta-wide sampling program, including the 20mm delta smelt survey, longfin smelt larva survey, summer tow net survey, and spring Kodiak Trawl sampling, occurs in the vicinity of this area. Longfin smelt have a short life span, with most reaching maturity at 2 years of age, when they spawn and then die. During the second year of life, adults tend to inhabit the higher salinity western portion of the estuary system; they occasionally have been found in nearshore ocean surveys (Rosenfield and Baxter 2007). Adults spend their life in bays, estuaries, and nearshore coastal areas and migrate into low-salinity or freshwater reaches of coastal rivers and tributary streams to spawn. Spawning occurs in the lower portions of the Sacramento and San Joaquin Rivers and adjacent sloughs typically between November and June, with peak spawning occurring from February through April (Baxter 1999; DWR 2009; Moyle 2002; Wang 1986). On the San Joaquin River, spawning occurs below Medford Island, approximately 20 miles downstream from the project site (Moyle 2002). Locations and movements of all life stages of longfin smelt are influenced by a wide range of hydrologic and environmental variables (Rosenfield 2010), all of which show high variation among and within years; accordingly, temporal and spatial distributions of longfin smelt show high variation among and within years.

CRITICAL HABITAT

Because the longfin smelt has not been listed, no critical habitat has been designated.

RECOVERY PLAN FOR LONGFIN SMELT

The *Sacramento–San Joaquin Delta Native Fishes Recovery Plan* includes the restoration of abundance and distribution of longfin smelt (USFWS 1996b). Action items in the recovery plan for longfin smelt refer to five zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of longfin smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Project area or action area.

CENTRAL VALLEY STEELHEAD DISTINCT POPULATION SEGMENT

On March 19, 1998, NMFS listed the Central Valley steelhead DPS as threatened (63 FR 13347). Central Valley steelhead DPS are considered to be winter-run steelhead (McEwan and Jackson 1996). Like other anadromous salmonid species, these fish mature in the ocean before entering freshwater on their spawning migrations. The major factor influencing steelhead populations in the San Joaquin River system is loss of habitat caused by construction of impassable dams on the mainstem and major tributaries.

Historically, Central Valley steelhead were found throughout the Sacramento and San Joaquin drainages, where waterways were accessible to migrating fish. Steelhead historically were present in the upper San Joaquin River basin, upstream of the current location of Friant Dam. Steelhead commonly migrated far up tributaries and into headwater streams where cool, well-oxygenated waters were present year round.

Currently, in the Central Valley, viable populations of naturally produced steelhead are found only in the Sacramento River and its tributaries. Wild steelhead populations appear to be restricted to tributaries of the Sacramento River below Keswick Dam, such as Antelope, Deer, and Mill Creeks, and to the Yuba River below Englebright Dam (McEwan and Jackson 1996). No significant populations of steelhead remain in the San Joaquin River basin; however, small persistent runs still occur on the Stanislaus River and perhaps the Tuolumne River (McEwan and Jackson 1996).

Juvenile steelhead rear throughout the year and may spend 1–3 years in freshwater before emigrating to the ocean. Smoltification, the physiological adaptation that juvenile salmonids undergo to tolerate saline waters, occurs in juveniles as they begin their downstream migration. Smolting steelhead generally emigrate from March to June (Barnhart 1986; Reynolds et al. 1993).

The San Joaquin River near the Phase 3 Project area is used by adult and juvenile steelhead primarily as a migration corridor between the ocean and cold-water habitat in the upstream tributaries. Juvenile steelhead would likely use the edges of rivers and sloughs for rearing as they emigrate (Moyle 2002).

CRITICAL HABITAT

Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins. The Phase 3 Project area is located within designated critical habitat for the Central Valley steelhead DPS.

RECOVERY PLAN FOR CENTRAL VALLEY STEELHEAD DISTINCT POPULATION SEGMENT

A public draft of the recovery plan for the ESUs of Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon and the DPS of Central Valley steelhead was prepared by NMFS in October 2009 (NMFS 2009). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives.

CENTRAL VALLEY FALL-/LATE FALL–RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

On September 16, 1999 (64 FR 50393), NMFS determined that listing was not warranted for the Central Valley fall-/late fall–run Chinook salmon ESU; however, the ESU was designated as a future candidate for listing because of concerns about specific risk factors. On April 14, 2004 (69 FR 19975) the ESU was reclassified as a species of concern. The ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin River basins and their tributaries, east of the Carquinez Strait. The Central Valley fall-/late fall–run Chinook salmon ESU is currently the only run of Chinook salmon in the San Joaquin River system.

Adult Central Valley fall-/late fall–run Chinook salmon enter the Sacramento and San Joaquin river systems from September through January and spawn from October through February. In general, San Joaquin River populations tend to mature at an earlier age and spawn later in the year than Sacramento River populations (Baker and Morhardt 2001). These differences may be phenotypic responses to the generally warmer temperature and lower flow conditions found in the San Joaquin River basin, relative to the Sacramento River basin.

Juveniles typically rear in freshwater for 3–6 months (fall-run) and up to 12 months (late fall–run) before entering the ocean. Juveniles migrate downstream from January through June. Juvenile Chinook salmon prefer water depths of 0.5 foot to 3.3 feet and velocities of 0.26 foot to 1.64 feet per second (Raleigh et al. 1986). Important winter habitat for juvenile Chinook salmon includes flooded bars, side channels, and overbank areas with relatively low water velocities. Juvenile Chinook salmon have been found to rear successfully in floodplain habitat, which routinely floods but is dry at other times. Growth rates appear to be enhanced by the conditions found in floodplain habitat (Sommer et al. 2001).

Cover structures, space, and food are necessary components for Chinook salmon rearing habitat. Suitable habitat includes areas with instream and overhead cover in the form of undercut banks, downed trees, and large, overhanging tree branches. The organic materials forming fish cover also help provide sources of food, in the form of both aquatic and terrestrial insects. Juvenile Chinook salmon grow more quickly in floodplain habitat than in river habitat. The water temperature is typically higher in floodplain habitat than in main-channel habitats. Although increased temperature increases metabolic requirements, the productivity in flooded habitat also is increased, resulting in higher growth rates (Sommer et al. 2001). The production of drift invertebrates has been found to be one to two times greater in the Yolo Bypass than in the river (Sommer et al. 2001). Also, grasses and other vegetation that are flooded support invertebrates that are also a substantial source of food for rearing juveniles. Increased areas resulting from flooded habitat also can reduce the competition for food and space and potentially decrease the possible encounters with predators (Sommer et al. 2001). Juvenile Chinook salmon that grow faster are likely to migrate downstream sooner, which helps to reduce the risks of predation and competition in freshwater systems.

Fall-run Chinook salmon adults primarily pass through the Phase 3 Project area on their way to spawn in upstream tributaries of the San Joaquin River (Moyle 2002). Juvenile fall-run Chinook salmon emigrate from San Joaquin River tributaries (e.g., the Stanislaus, Merced, and Tuolumne Rivers) and other river tributaries through the San Joaquin River during the late winter and spring (February through mid-June) (San Joaquin River Group Authority 2009). Juvenile Chinook salmon use the edges of rivers and sloughs for rearing as they emigrate downstream (Moyle 2002).

CRITICAL HABITAT

No critical habitat has been designated for Central Valley fall-/late fall–run Chinook salmon.

ESSENTIAL FISH HABITAT

EFH has been designated for Central Valley fall-/late fall–run Chinook salmon ESU and is within the Phase 3 Project area along the San Joaquin River. Fall-run EFH includes migration, holding, and rearing habitat for the San Joaquin River (fall-run only) (NMFS 2014). Late fall–run EFH includes opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014).

RECOVERY PLAN FOR CENTRAL VALLEY FALL-/LATE FALL–RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

Although the Central Valley fall-/late fall–run Chinook salmon is not listed as threatened or endangered under the ESA, the *Sacramento–San Joaquin Delta Native Fishes Recovery Plan* outlines conservation measures and restoration objectives and criteria for the species, including the San Joaquin River run, which CDFW recognizes as a distinct stock (USFWS 1996b). Reasons for decline identified by the plan include habitat loss, suitability of habitat, survival of outmigrants, harvest, hatcheries, and water quality. Conservation measures include:

- testing of an electrical fish barrier and a physical barrier upstream of the confluence of the Merced River to prevent straying of adult fish,
- construction and rehabilitation of spawning riffles,
- construction of a temporary barrier at Old River to prevent entrainment of outmigrating smolts, and when possible,
- coordination of water releases to provide attraction or outmigration flows.

These efforts have been funded by a wide range of federal, state, and private agencies (USFWS 1996b).

SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

The Sacramento River winter-run Chinook salmon was formally listed as threatened in November 1990 (55 FR 46515), and was reclassified as endangered under the ESA on January 4, 1994 (59 FR 440).

In the Delta, winter-run adults begin to move through the system in early winter (November–December), with the first upstream adult migrants appearing in the upper Sacramento River during late December (Vogel and Marine 1991, cited in NMFS 2003). Adult winter-run presence in the upper Sacramento River system peaks in March. The timing of migration may vary somewhat because of changes in river flows, dam operations, and water year type. Spawning occurs primarily from mid-April to mid-August, with peak activity occurring in May and June in the river reach between Keswick Dam and the Red Bluff Diversion Dam (Vogel and Marine 1991, cited in NMFS 2003).

Juvenile winter-run Chinook salmon occur in the Delta from October through early May, based on data collected from trawls, beach seines, and salvage records at state and federal water projects (DFG 1998). The peak of juvenile arrivals is from January to March. Juveniles tend to rear in the freshwater upper Delta areas for about the first 2 months (Kjelson et al. 1981, 1982). As they mature, winter-run Chinook fry and fingerlings prefer to rear farther downstream where ambient salinity is up to 1.5 to 2.5 parts per thousand (Healey 1980, 1982; Levings et al. 1986). Fry remain in the estuary until they reach a fork length of about 118 millimeters (i.e., at 5–10 months of age). Emigration from the Delta may begin as early as November and continue through May (Fisher 1994; Myers et al. 1998).

With the exception of occasional strays, adult winter-run Chinook salmon generally do not occur in the San Joaquin River or in this portion of the Delta, and therefore, do not occur in the action area.

CRITICAL HABITAT

Critical habitat for the winter-run Chinook salmon ESU was designated by NMFS on June 16, 1993 (58 FR 33212), with an effective date of July 16, 1993. Critical habitat is designated to include the Sacramento River from Keswick Dam (River Mile 302) to Chipps Island (River Mile 0) and all waters westward, including San Francisco Bay north of the Bay Bridge to the Golden Gate Bridge. The proposed action is not within designated critical habitat.

ESSENTIAL FISH HABITAT

Although EFH has been identified for Sacramento River winter-run Chinook salmon ESU (NMFS 2014), NMFS's EFH map does not show EFH for this species within the Phase 3 Project area.

RECOVERY PLAN FOR SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

A public draft of the recovery plan for the ESUs of Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon and the DPS of Central Valley steelhead was prepared by NMFS in October 2009 (NMFS 2009). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Recovery goals and restoration actions for this species ESU are described for the Sacramento River basin and do not apply to the action area, since reintroduction of winter-run Chinook salmon is not planned for the action area.

CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

NMFS listed Central Valley spring-run Chinook salmon as threatened on September 16, 1999 (50 FR 50394).

Central Valley spring-run Chinook salmon were historically the second most abundant run of Central Valley Chinook salmon (Fisher 1994). They occupied the headwaters of all major river systems in the Central Valley where no natural barriers existed. Adults returning to spawn ascended the tributaries to the upper Sacramento

River, including the Pit, McCloud, and Little Sacramento Rivers. They also occupied Cottonwood, Battle, Antelope, Mill, Deer, Stony, Big Chico, and Butte Creeks and the Feather, Yuba, American, Mokelumne, Stanislaus, Tuolumne, Merced, San Joaquin, and Kings Rivers. Spring-run Chinook salmon migrated farther into headwater streams where cool, well-oxygenated water was available year round.

Surveys indicate that populations of remnant, nonsustaining spring-run Chinook salmon may be found in Cottonwood, Battle, Antelope, and Big Chico Creeks (DWR 1997); more sizable, consistent runs of naturally produced fish are found only in Mill and Deer Creeks. All these creeks are tributaries in the Sacramento River basin. The Feather River Fish Hatchery sustains the spring-run population on the Feather River, but the genetic integrity of that run is questionable (DWR 1997).

Like winter-run Chinook salmon, adult spring-run Chinook salmon other than occasional strays generally do not occur in the San Joaquin River basin, and therefore, do not occur in the action area.

CRITICAL HABITAT

Critical habitat for the Central Valley spring-run Chinook salmon was designated on August 12, 2005; a final designation was published on September 2, 2005, with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include selected waters in the Sacramento River basin from approximately Redding (River Mile 302) to approximately Chipps Island (River Mile 0) at the westward margin of the Delta and includes the Sacramento River. The Phase 3 Project area is located outside of designated critical habitat.

ESSENTIAL FISH HABITAT

Although EFH has been identified for Central Valley spring-run Chinook salmon ESU (NMFS 2014), NMFS's EFH map does not show EFH for this species within the Phase 3 Project area.

RECOVERY PLAN FOR CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

A public draft of the recovery plan for the ESUs of Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon and the DPS of Central Valley steelhead was prepared by NMFS in October 2009 (NMFS 2009). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Recovery goals and restoration actions are outlined for the Sacramento River basin and do not apply to the action area.

As discussed above in the "San Joaquin River" subsection of the "Environmental Baseline" section, one of the goals of the SJRRP is "to restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish" (Reclamation and DWR 2011). The Settlement stipulates reintroduction of spring-run and fall-run Chinook salmon, with a priority given to restoring self-sustaining populations of wild spring run Chinook salmon.

NORTH AMERICAN GREEN STURGEON DISTINCT POPULATION SEGMENT

On April 7, 2006, NMFS listed the Southern DPS of the North American green sturgeon as threatened under the ESA. In North America, green sturgeon are found from Ensenada, Mexico, to southeast Alaska. The Southern DPS includes individual reproductive populations south of the Eel River. The populations north of the Eel River, grouped as the Northern DPS, currently do not warrant listing.

Green sturgeon are found in the lower reaches of large rivers, including the Sacramento–San Joaquin River basin, and in the Eel, Mad, Klamath, and Smith Rivers. Green sturgeon adults and juveniles are found throughout the upper Sacramento River, as indicated by observations incidental to winter-run Chinook monitoring at Red Bluff Diversion Dam in Tehama County (NMFS 2005). Green sturgeon spawn predominantly in the upper Sacramento River and are found primarily in the mainstem Sacramento River.

The green sturgeon is a primitive, bottom-dwelling fish characterized by its large size (up to 7 feet long and 350 pounds); a long, round body; and "scutes" or plates along dorsal and lateral sides. It is known to migrate up to 600 miles between freshwater and salt water environments and is commercially caught in the Columbia River and coastal Washington (PFMC 2003). Very little is known about the life history of the green sturgeon relative to other fish species. Like all sturgeon species, it is anadromous, but it is also the most marine-oriented of the sturgeon species (NMFS 2005). It spends most of its life in salt water and returns to spawn in freshwater. It is slow growing and late maturing, and may spawn as little as every 4–11 years. Individuals congregate in the bays of these systems in summer, while some may travel upstream to spawn in spring and summer.

Green sturgeon spawning has been documented only in the Klamath, Sacramento, and Rogue Rivers during recent times (NMFS 2005). Green sturgeon spawning in the San Joaquin River is not well documented.

Information about population trends for the Southern DPS of green sturgeon is less definitive than information about the Northern DPS, and the populations face a larger number of potential threats. In addition to the sizeable threats faced by the Northern DPS, green sturgeon populations in the Southern DPS face smaller population sizes, potentially lethal temperature limits, entrainment by water projects, and influences of toxic material and exotic species. Population sizes are unknown for this DPS but are clearly much smaller than for the Northern DPS, and therefore, are more susceptible to catastrophic events. This makes the lack of information about population trends an even greater risk factor.

Green sturgeon may occur in the San Joaquin River between Stockton and the Highway 140 bridge (IEP 2013), including in the Phase 3 Project area. No documentation exists for green sturgeon spawning in the San Joaquin River, but spawning probably occurred before construction of large-scale hydropower and irrigation development. White sturgeon persist in the San Joaquin River at population levels of 10% of Sacramento River population levels. Young green sturgeon have been taken occasionally in the Santa Clara Shoal area in the Delta, but these fish may have originated somewhere else (NMFS 2005).

Critical Habitat

Critical habitat for green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

Recovery Plan for North American Green Sturgeon Distinct Population Segment

A recovery plan has not been developed for green sturgeon.

EFFECTS

DIRECT AND INDIRECT EFFECTS ON SPECIES IN THE ACTION AREA

Under the ESA, direct effects are those that are caused by the project and that occur at the same time as the action (see, e.g., construction-related effects). Indirect effects are those that are caused by the proposed action and are later in time, but are reasonably certain to occur (e.g., operational effects). Avoidance and minimization measures for both direct and indirect effects are presented in the "Avoidance and Minimization Measures" section above.

VALLEY ELDERBERRY LONGHORN BEETLE

There are no known documented occurrences of VELB in the Phase 3 Project area, but the species could use elderberry shrubs in the action area. Elderberry shrubs that could support beetles are sparsely scattered throughout the action area, along both the waterside and landside of the San Joaquin River levee.

Eighteen elderberry shrubs are present in or adjacent to the footprint of the Phase 3 Project. The nine elderberry shrubs located along the waterside of the Phase 3 Project levees would be avoided and protected during construction (see "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle"). The nine elderberry shrubs located along the landside of the levee would require removal to accommodate construction of the Phase 3 Project's seepage berms, cutoff walls, and setback levee (**Table 3**; **Exhibit 14**). However, one of these landside shrubs does not have stems greater than one inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

Table 3
Survey Results for Landside Elderberry Shrubs that Would be Removed from the Phase 3 Project Levee Improvements Area

Shrub Number	Number of Stems per Diameter Category (inches)			Beetle Exit Holes Present?	Riparian?[1]
	≥ 1 and ≤ 3	≥ 3 and ≤ 5	≥ 5		
9	0	0	0	No	No
10	73	6	0	No	No
11	25	17	8	No	No
13	12	4	4	No	No
14	5	4	2	No	No
15	32	11	2	No	No
16	13	4	1	No	No
17	25	4	5	No	No
18	6	5	0	No	No
Total	**191**	**55**	**22**		

Notes:
[1] Riparian = waterside of levee. Nonriparian = landside of levee.
Source: Data compiled by AECOM in 2014

The eight elderberry shrubs on the landside have a total of 268 stems that are greater than 1 inch in diameter at ground level. These shrubs would require removal during the construction of the Phase 3 Project, resulting in direct effects on VELB. If the stems are occupied by beetles, any early-stage individuals are likely to be killed when the shrub is removed. Complete loss of the shrubs to be removed should be avoided by transplanting during the shrubs' dormant season; however, transplanted elderberry shrubs can experience stress or health problems because of changes in soil, hydrology, microclimate, or associated vegetation, and mortality of transplanted shrubs precludes their future use by the beetle. Removing shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected; alternately, adverse effects on elderberry shrubs could have an overall effect on the beetle, even if larvae are absent at the time of impact, if the shrubs are relied upon for reproduction. In addition, it takes 5 or more years for replacement elderberry plantings to reach a size conducive to use as VELB habitat. Therefore, there would be a temporary loss of habitat available to the beetle. The Phase 3 Project would comply with avoidance and minimization measures described for VELB and compensation for removal of these stems would be provided in accordance with the VELB Guidelines (USFWS 1999). A net reduction in the number of elderberry shrubs would be avoided by requiring establishment of 367 elderberry seedlings and 367 associated native plantings. RD 17 would purchase VELB habitat conservation credits comparable to this amount of seedlings from a USFWS-approved VELB habitat conservation bank to compensate for effects on VELB.

RIPARIAN BRUSH RABBIT

As shown in **Table 4**, the Phase 3 Project levee improvements would result in the removal of 3.28 acres of landside riparian habitat—specifically Great Valley cottonwood riparian forest and Great Valley oak riparian forest—that is suitable for riparian brush rabbit. This riparian habitat is located on the landside of the levee, where levee improvements (e.g., chimney drains, seepage berms) would be constructed. In general, most of the landside riparian vegetation is sparse and lacks understory vegetation other than grasses and ruderal vegetation, which would act as cover for riparian brush rabbit and is not suitable for this species (Hansen, pers. comm., 2011). However, there is potential for some of these landside woody habitats to support suitable habitat for riparian brush rabbit, particularly because these are located adjacent to waterside riparian habitats that either are known to be occupied by this species or are highly suitable habitat. All landside riparian habitat was considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied or highly suitable for riparian brush rabbit (i.e., Element IIab through Element VIe). North of Element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., Elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species. No waterside woody or riparian habitat would be removed as a result of levee improvement activities.

Table 4
Effects of Implementing the Phase 3 Project on Suitable Riparian Brush Rabbit Habitats

	Acres of Directly Affected Suitable Habitat
Waterside woodlands[1]	0.00
Landside woodlands[1,2]	3.28
TOTAL	3.28

Notes:
1 Suitable riparian brush rabbit habitats are characterized as Great Valley cottonwood riparian forest and Great Valley oak riparian forest.
2 Most of the landside riparian vegetation is sparse and lacks understory and is not suitable for this species (Hansen, pers. comm., 2011). However, any landside riparian habitat was considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied by or highly suitable for riparian brush rabbit (i.e., Element IIab through Element Vie). North of Element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., Elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.
Source: Data compiled by AECOM in 2014

Nearly 54 acres of ruderal annual grassland would also be affected by Phase 3 Project implementation. All effects on ruderal annual grassland that would result from levee improvements are assumed to be temporary because annual grassland would be reestablished in these areas after project completion. Although riparian brush rabbit may use annual grassland as a source for foraging habitat, the key component of habitat suitability for this species in the Phase 3 Project area is based on the presence of riparian woody vegetation, and not the surrounding grasslands. Riparian brush rabbits forage along the edges of shrub cover and in small clearings in the vegetation cover, rather than in large openings, feeding on herbaceous vegetation such as grasses, sedges, clover, forbs, buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). Further, because this species is known to have a small home range and seldom ventures more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006), the riparian brush rabbit likely uses only a small component of the grassland and its use of such habitat is concentrated along the edges of the riparian areas.

The loss of potential riparian brush rabbit habitat in the Phase 3 Project area could restrict the range of this species because the RD 17 area currently contains the northernmost known extent of the population on the San Joaquin River. It also could isolate other populations residing in residual habitats in the project vicinity. However, the proposed conservation measures (see the "Avoidance and Minimization Measures" and "Compensation Measures" sections above) would minimize direct take in conjunction with compensation for adverse effects. Implementing such measures is anticipated to avoid a net reduction in the number of riparian brush rabbits. The Phase 3 Project includes the restoration of approximately 4.52 acres of riparian habitat in the setback area at Element IVc (**Exhibit 12**). The expansion and restoration of riparian habitat in Element IVc would augment the waterside riparian corridor along the San Joaquin River and provide additional riparian habitat opportunities for the riparian brush rabbit between two known occurrences of this species (i.e., between Elements IIIa/IIIb and Elements VIa.1/VIa.4 [CNDDB 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). As stated under the "Compensation Measures" section above, in addition to the habitat restoration proposed in Element IVc, RD 17 is investigating additional habitat compensation opportunities at off-site locations.

FEDERALLY LISTED FISH SPECIES

Fish species/ESUs addressed in this BA would likely use similar habitat in the action area. Therefore, the direct and indirect effects on delta smelt, longfin smelt, Central Valley fall-/late fall–run Chinook salmon, Central Valley steelhead, and green sturgeon are discussed together. Effects on Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon, which are unlikely to occur in the action area but may occasionally occur as strays, would be similar.

TEMPORARY CONSTRUCTION-RELATED EFFECTS

The Phase 3 Project would involve constructing several cutoff walls, which would entail degrading the top one-third to one-half of the levee, beginning with a 1:1 cut at the waterside crown. Implementing cutoff walls as part of the Phase 3 Project would disturb soils along the top of the levee, which through wind and water erosion could enter the San Joaquin River. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately be pumped into the San Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff.

Fish population levels and survival have been compared to various levels of turbidity and siltation in waterways. Prolonged exposure to high levels of suspended sediment could create a loss of visual capability in fish, leading to a reduction in feeding and growth rates, and to a thickening of the gill epithelia, which may cause the loss of respiratory function; clogging and abrasion of gill filaments; and increases in stress levels, reducing the tolerance of fish to disease and toxicants (Waters 1995). Also, high levels of suspended sediments could cause the movement and redistribution of fish populations or other aquatic organisms, and could affect physical habitat (Waters 1995). Sediment loading could interfere with photosynthesis of aquatic flora and displace aquatic fauna. Many fish and other aquatic species are sight feeders, and turbid waters reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, could become disoriented and leave areas where their main food sources were located, ultimately reducing their growth rates. Increased turbidity and sedimentation cause fish to avoid an area, thus reducing available habitat. Fish will not occupy areas unsuitable for survival unless they have no other option. Therefore, construction-related erosion could result in elevated river turbidity in critical species-specific and life stage-specific habitats, potentially precluding a species from occupying that habitat. In addition, the potential would exist for contaminants such as bentonite slurry, fuels, oils, and other products used in construction to be introduced into the waterway directly or through surface runoff. Contaminants might be toxic to fish, or might alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival.

Through the implementation of water quality BMPs, including a SWPPP, the proposed conservation measures (see the "Avoidance and Minimization Measures" section above) would avoid direct and indirect take of fish during construction. The impact would not be expected to have an effect on the overall existence and survival of these species.

PERMANENT CONSTRUCTION-RELATED EFFECTS

Most waterside woodlands in the Phase 3 Project area are assumed to provide SRA habitat functions. Apart from the placement of 1.136 acre of riprap above the HTL along the waterside levee at Element IVc, the Phase 3 Project would not involve performing any work on the waterside of the levee, and no waterside woodlands or SRA habitat would be removed. Therefore, construction-related effects on the habitats of federally listed fish species would be limited to minor disturbance of the waterside levee at two locations that are above the HTL and that are characterized by ruderal vegetation.

Because all Phase 3 Project construction activities would occur above the HTL and no SRA habitat would be removed, the Phase 3 Project would not result in adverse effects on Central Valley steelhead, Delta smelt, longfin smelt, Sacramento River winter-run and Central Valley fall- and spring-run Chinook salmon, or green sturgeon.

CUMULATIVE EFFECTS

Cumulative effects include the effects of present, pending, and future state, tribal, local, or private actions that are reasonably certain to occur within the action area under consideration. The effects of projects that require a federal action are not considered in the cumulative effects evaluation during Section 7 consultation evaluation because they are subject to separate consultation (USFWS and NMFS 1998). For example, the Central Lathrop Specific Plan (Phase 1), addresses the development of 1,521 acres of land immediately east of the RD 17 levee Elements IIIa and IIIb, south of Dos Reis and north of the housing development adjacent to Element IVa. The USFWS issued a biological opinion for this project (USFWS File No. 1-1-06-F-0114), which analyzed the effects of the project on riparian brush rabbit and VELB. Therefore, this development is not considered cumulative to the proposed project. Also, the nonfederal action must be located in the action area, or project site, that is evaluated in the Section 7 consultation process (USFWS and NMFS 1998). Several present, pending, and future projects that are located in or near the action area under consideration in this consultation could result in effects similar to those of the proposed action.

SUMMARY OF PRESENT, PENDING, AND FUTURE PROJECTS IN THE PROPOSED PHASE 3 PROJECT AREA

FLOOD DAMAGE REDUCTION SYSTEM IMPROVEMENTS

Two other proposed projects related to improvements to flood damage reduction systems are located near RD 17: the Lower San Joaquin River Feasibility Study, which would determine needed improvements for future flood protection systems in an effort to reach or exceed the future 200-year level of flood protection; and the Smith Canal Closure Structure, which would install a flood control gate in the Delta in Stockton north of the Deep Water Ship Channel to prevent flood flows from entering the Smith Canal in the event of an imminent or existing levee breach and during 100-year flood events.

DEVELOPMENT PROJECTS

Development projects within the RD 17 boundaries include projects in the cities of Manteca, Stockton, and Lathrop, and in unincorporated areas of San Joaquin County. These projects have been described and analyzed in their respective environmental documents, including:

- River Islands Project;
- San Joaquin County General Plan 2010, adopted in 1992 and as amended;
- *City of Stockton General Plan*, adopted in 1990 and as amended through November 3, 1998;
- *City of Lathrop General Plan*, adopted in 1991 and as amended through January 2003;
- Central Lathrop Specific Plan, adopted in November 2004;
- West Lathrop Specific Plan, adopted in 1995;
- *Manteca General Plan*, adopted in 1988 and as amended through December 20, 1993;
- City of Lathrop Water, Wastewater, and Recycled Water Master Plan, adopted in 2001 and as amended through November 9, 2004;
- expansion of the City of Manteca Wastewater Treatment Plant; and

- *2001 Regional Transportation Plan*, San Joaquin Council of Governments, 2001.

San Joaquin County covers approximately 909,000 acres, with approximately 809,000 acres, or nearly 90%, of the county used or available for agriculture (row and field crops, orchards, vineyards, and grazing lands). The remaining lands are dominated by various types of development (approximately 59,000 acres), natural habitats (woodlands, riparian), and open water (lakes, rivers, Delta waterways). Most county residents and development are located in incorporated cities (Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton, and Tracy). The SJMSCP anticipated that 147,000 acres of various categories of open space lands (including agriculture, range lands, and natural) in the county would be converted to non–open space uses between 2001 and 2051, based on full buildout of each of the general plans in the county and construction of all anticipated utility, transportation, and other public projects. In addition, approximately 59,000 acres of infill of urban lands were presumed to occur in this 50-year time frame.

Many projects near the Phase 3 Project site, including those described above, have been implemented recently or are in various stages of planning and entitlement, including the River Islands project. These current, pending, and potential future projects may affect federally listed species and require a federal action, and would therefore be subject to Section 7 consultation. In addition, most projects within San Joaquin County are expected to seek incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Project because they would undergo federal review and permitting as necessary, which would ensure that adverse effects are fully mitigated and would not threaten successful implementation of the SJMSCP.

ANALYSIS OF CUMULATIVE EFFECTS

GROWTH INDUCEMENT

Direct growth inducement would result if a project involves construction of new housing. Indirect growth inducement would occur, for instance, if implementing a project were to result in any of the following:

- substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises);
- substantial short-term employment opportunities (e.g., construction employment) that indirectly would stimulate the need for additional housing and services to support the new temporary employment demand; and/or
- removal of an obstacle to additional growth and development, such as removing a constraint on a required public utility or service (e.g., construction of a major sewer line with excess capacity through an undeveloped area).

Indirect effects might include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density, or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Local land use decisions are within the jurisdiction of the cities and county in the Phase 3 Project area: the City of Stockton, the City of Lathrop, the City of Manteca, and San Joaquin County. Each of these cities and county has adopted a general plan consistent with state law. These general plans provide an overall framework for growth and development within the jurisdiction of each agency, including the Phase 3 Project area. Within the RD 17 boundaries, as elsewhere, population growth and urban development are also influenced by national, regional, and local economic conditions.

Because the Phase 3 Project would not involve the construction of housing, it would not directly induce growth. Construction activities would generate short-term employment, but it is anticipated that construction jobs would be filled from the existing local employment pool and would not indirectly induce growth or result in a population increase, nor would implementation of the project indirectly induce growth by creating permanent new jobs.

The Phase 3 Project would accommodate growth currently approved or planned for undeveloped lands within the boundaries of RD 17. These lands have been identified as the places most suitable for urban growth in the general plans and additional planning policy documents of the cities of Lathrop, Manteca, and Stockton, and San Joaquin County. The Phase 3 Project would allow development to proceed when economic and market conditions are favorable.

Development within the boundaries of RD 17 is directed by the *Central Lathrop Specific Plan* and the *West Lathrop Specific Plan* in the City of Lathrop, the *City of Stockton General Plan*, the *City of Manteca General Pla*n, and the *San Joaquin County General Plan*. The Cities of Lathrop and Manteca are where the majority of planned or proposed development projects would be located. Environmental documents were prepared to address the general plans in these areas.

This information provides substantial evidence that the Phase 3 Project would accommodate anticipated growth in a manner that would be consistent with adopted local growth management plans and with the state's emerging State Plan of Flood Control. Thus, the Phase 3 Project, despite accommodating buildout of adopted specific plans and general plans in the cities of Lathrop, Manteca, and Stockton, is not growth inducing itself.

CUMULATIVE EFFECTS ON LISTED SPECIES

Implementing the plans and projects described above would permanently disturb undeveloped land that is currently or has recently been in agricultural use. These projects would have cumulative effects on agricultural resources (by converting agricultural land to nonagricultural uses) and remnant native habitats (such as woodlands and marshes), which would have the potential to cause permanent adverse cumulative effects on the species, including federally listed species, for which these lands provide habitat.

Large areas of native riparian and wetland vegetation in the Phase 3 Project area and Central Valley region have been lost or degraded in the past 150 years. USFWS estimates that more than 90% of wetland and riparian habitat has been lost in the Central Valley compared to historic levels (USFWS 1989). Most losses have occurred as a result of CVP and SWP facility construction and alteration of flow patterns below dams, particularly channelization, and then clearing or filling behind levees for the conversion to agriculture and urban land uses. This habitat conversion has substantially affected many plant and wildlife species, resulting in various species being listed as threatened or endangered under the ESA as well as the California Endangered Species Act.

Present and future conversions of open space lands in San Joaquin County and the region consist primarily of converting agricultural lands to residential and urban development. Several flood risk management projects are being implemented across the Central Valley, including San Joaquin County, to improve the integrity of levees. Some of these flood risk management projects, however, would implement compensatory mitigation in the form of habitat creation and preserves designed to actually increase these habitats and their values related to ecosystem functions and special-status species. Upstream of the Phase 3 Project area, the San Joaquin River Restoration Program would result in future structural and channel improvements to benefit special-status fish and wildlife species (Reclamation and DWR 2011).

Still, even with these benefits, the overall losses of sensitive habitats in the Phase 3 Project region, the numerous threatened and endangered species that are present, the ongoing declines of other species, and the continuing conversions of habitats and open space lands to various developments are evidence that past, present, and reasonably foreseeable future projects combine to result in significant cumulative impacts on biological resources.

When combined with past, present, and future projects, the implementation of the Phase 3 Project has the potential to contribute to the loss or degradation of sensitive riparian and wetland habitats and adversely affect special-status species. Numerous special-status fish occur in the San Joaquin River, and special-status wildlife, including VELB, riparian brush rabbit, and special-status fish species, are either known or have the potential to occur in the Phase 3 Project area.

The Phase 3 Project has the potential to temporarily degrade water quality and fish habitat and populations in the San Joaquin River through the indirect release (i.e., runoff) of soil or contaminants. The extensive array of development projects anticipated in the region and other flood risk management projects would have a similar potential to release materials into the San Joaquin River. Potential increases in sedimentation, turbidity, and contaminants could expose and adversely affect fish and aquatic habitats. Alterations to the San Joaquin River channel have resulted over time in homogenous, trapezoidal channels with little instream structure; narrow and sparse bands of riparian vegetation that provide only limited SRA habitat functions; limited recruitment of large woody debris; and limited habitat conditions for native fish species and other aquatic organisms. The Phase 3 Project would not remove any waterside riparian habitat or SRA habitat along the lower San Joaquin River. Further, because historic channel alterations have resulted in marginal habitat conditions that provide only limited habitat functions for most native fish species and other aquatic organisms, the Phase 3 Project would offset the overall loss and degradation of suitable habitat, including degraded water quality for special-status fish species in the action area through the expansion and restoration of waterside riparian habitat in the setback area at Element IVc.

Effects on terrestrial wildlife and fish species, including federally listed and state-listed species, would be associated with removal of landside vegetation as needed to clear ground for the Phase 3 Project, construction disturbances to wildlife and their habitats, and permanent and temporary losses of foraging and breeding habitat for the affected species. Approximately 3.28 acres of landside riparian forest would be removed as a result of project implementation. Although most of the habitat is considered low quality, even small losses could contribute to species declines and losses of habitat, similar to those that have led to the need to protect these species under the ESA.

However, the Phase 3 Project incorporates compensatory measures (see the “Compensation Measures” section above) to offset losses of riparian habitats. These measures include creating approximately 4.52 acres of riparian habitat in the setback area at Element IVc (**Exhibit 12**), as well as other off-site habitat compensation opportunities. These efforts would increase the amount of higher quality habitat available along these reaches of the San Joaquin River.

CONCLUSIONS AND DETERMINATION

In conclusion, based on the biology and ecology of the federally listed species that have the potential to occur in the Phase 3 Project area, the environmental baseline for the action area, and the effects of the proposed action and its cumulative effects, implementing the Phase 3 Project may affect and is likely to adversely affect VELB and riparian brush rabbit, and would result in no effect on delta smelt, Central Valley fall-/late fall–run Chinook salmon, Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, and green sturgeon. Designated critical habitat in the action area has been designated for delta smelt, Central Valley steelhead, and green sturgeon; however, none would be adversely modified or destroyed.

- **Valley elderberry longhorn beetle:** The Phase 3 Project may affect and is likely to adversely affect VELB through the transplantation of eight elderberry shrubs. Although VELB habitat credits would be purchased comparable to 367 elderberry seedlings and 367 associated native plantings would be purchased from a USFWS-approved VELB habitat conservation bank to compensate for effects to VELB and effects to 268 elderberry stems (greater than 1 inch in diameter at ground level), there could be an effect on the species. Removal of shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected and there would be a temporary loss of habitat available to the beetle during the establishment of seedlings.

- **Riparian brush rabbit:** The Phase 3 Project may affect and is likely to adversely affect riparian brush rabbit through the removal of 3.28 acres of landside riparian habitat that is suitable for the species, contributing to the further reduction of available habitat for this species.

However, the Phase 3 Project would involve restoring approximately 4.52 acres of compensatory riparian habitat (**Exhibit 12**) to offset project-related habitat losses. Once the new setback levee in Element IVc is constructed and certified, a small section of the existing levee would then be partially degraded. Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4.52 acres that could be restored as riparian habitat (**Exhibit 12**). The restored riparian habitat would consist of willows, cottonwoods, valley oaks, wild rose, and California blackberry, and grasses, which is comparable to the composition of habitats where this species is documented to occur along the RD 17 levees. Apart from a small notch along the north side, the existing levee would remain in place, thus providing upland refugia for the species during high-water events. The 4.52-acre area would be contiguous with existing waterside riparian habitat along Element IVc; this waterside riparian habitat along Element IVc extends northward through Elements IVa, IIIa, and IIIb, and southward through Elements Va and VIa.1. There are documented occurrences of riparian brush rabbit in the waterside riparian habitat in Elements IIIa and IIIb, north of Element IIIa and south of Element VIa.1; therefore, reestablishing and protecting riparian habitat in Element IVc would provide expanded and connected habitat for this species.

RD 17 is also evaluating options for providing off-site compensatory habitat to offset Phase 3 Project effects on riparian brush rabbit. Additional off-site compensatory habitats would include preserving existing waterside riparian habitats and/or restoring natural riparian habitats. These options would be evaluated in coordination with USFWS during the Section 7 consultation.

- **Federally listed fish species:** The Phase 3 Project would result in no effect on federally proposed and federally listed fish species considered in this BA. Effects are not expected to occur because of the avoidance and minimization measures incorporated into the Phase 3 Project. The Phase 3 Project includes several measures that would avoid potential direct environmental effects during project construction. The potential impacts of increased sedimentation or turbidity, and/or release of contaminants on fish and other aquatic organisms, would be avoided and minimized through the use of BMPs (e.g., source control, detention basins, revegetation, and spill containment plan) that would maintain surface water quality conditions in receiving waters and minimize disturbance to fish and other aquatic habitats. No waterside riparian or SRA habitat would be removed.

ESSENTIAL FISH HABITAT ASSESSMENT

The Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801), requires that EFH be identified and described in federal fishery management plans. Federal agencies must consult with NMFS on any activity that they fund, permit, or carry out that may adversely affect EFH. The EFH regulations require that federal agencies obligated to consult on EFH also provide NMFS with a written assessment of the effects of any action on EFH (50 CFR 600.920). NMFS is required to provide EFH conservation and enhancement recommendations to federal agencies. The statute also requires federal agencies receiving NMFS EFH conservation recommendations to provide a detailed written response to NMFS within 30 days of receipt, detailing how they intend to avoid, mitigate, or offset the impact of activity on EFH (Section 305[b][4][B]).

EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. For the purposes of interpreting the definition of EFH, "waters" includes aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include areas historically used by fish where appropriate; "substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities; "necessary" means habitat required to support a sustainable fishery and a healthy ecosystem; and "spawning, breeding, feeding, or growth to maturity" covers all habitat types used by a species throughout its life cycle.

The Pacific Fishery Management Council has identified and described EFH, adverse impacts, and recommended conservation measures for salmon in Amendment 14 to the *Pacific Coast Salmon Plan* (PFMC 2003). Freshwater EFH for Pacific salmon in the Central Valley includes waters currently or historically accessible to salmon within the Central Valley ecosystem, as described in Myers et al. (1998), and includes the segment of the San Joaquin River in the action area. Central Valley fall-/late fall–run Chinook salmon is a species managed under the *Pacific Coast Salmon Plan* that occur in the San Joaquin River.

THE PROPOSED ACTION

The proposed action is described in detail in the "Description of the Proposed Action" section of this BA. The action area, environmental baseline, and species accounts, respectively, are described in the "Action Area," "Environmental Baseline," and "Species Accounts" sections of this BA.

ESSENTIAL FISH HABITAT DESIGNATION IN THE ACTION AREA

EFH has been identified for Central Valley fall- and late fall–run Chinook salmon. Fall-run EFH includes migration, holding, and rearing habitat for the San Joaquin River (NMFS 2014). Late fall–run EFH includes opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014). No EFH has been designated in the action area for other fish species addressed in this BA.

EFFECTS OF THE PROPOSED ACTION

Effects of the proposed action are described in the "Effects" and "Cumulative Effects" sections of this BA.

PROPOSED CONSERVATION MEASURES

Proposed conservation measures are presented in the "Description of the Proposed Action" and "Effects" sections of this BA. The measures include avoidance and minimization measures.

CONCLUSIONS

On review of the effects, the proposed action will not affect the spawning, rearing, and migratory EFH functions of Chinook salmon currently or previously managed under the Magnuson-Stevens Fishery Conservation and Management Act in the San Joaquin River.

Alicia E. Kirchner
Chief, Planning Division
Department of the Army
U.S. Army Corps of Engineers, Sacramento District
1325 J Street
Sacramento, California 95814-2922

Dear Ms. Kirchner:

This letter is in response to your letter dated March 27, 2015, requesting the initiation of informal consultation with NOAA's National Marine Fisheries Service (NMFS) pursuant to section 7 of the Endangered Species Act (ESA) of 1973, as amended (16 U.S.C. 1531 *et seq.*), concerning Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair Project (Project). This letter was received by NMFS' California Central Valley Office (Mr. Howard Brown) on April 7, 2015. The U.S. Army Corps of Engineers (Corps) has determined that the proposed project "may affect, but is not likely to adversely affect" federally listed as threatened California Central Valley (CV) steelhead (*Oncorhynchus mykiss*), threatened CV spring-run Chinook salmon (*O. tshawytscha*), and threatened Southern distinct population segment (DPS) of North American green sturgeon (*Acipenser medirostris*). In addition, the Corps has determined that the Project actions "will not result in destruction or adverse modification" of designated critical habitat for California Central Valley steelhead and southern DPS of North American green sturgeon. Finally, the Corps has determined that the proposed Project actions "will not adversely affect designated Chinook salmon EFH" for both short-term and long-term construction actions.

NMFS has reviewed the BA included with the consultation request letter and concluded it lacks sufficient detail to determine the extent to which the proposed project may affect federally listed species and their designated critical habitats. In addition, we find that the information provided in the BA is incomplete and we have not received all the information that would be necessary to initiate section 7 consultation on the proposed project, as outlined in the regulations governing interagency consultation (50 CFR §402.12). It is the responsibility of the Federal agency requesting consultation to provide NMFS with all information necessary to initiate consultation.

Separation of the Environmental baseline from the Proposed Action

The BA has described physical and biological conditions that exist in the Project area. Separating the impacts of the current environmental baseline from the effects of the ongoing action as represented by the presence of the levees is an important consideration. The baseline is an analysis of the effects of past and ongoing human and natural factors leading to the current status of the species, its habitat (including designated critical habitat), and the ecosystem within the action area. The baseline does not include the effects of the action under review in the consultation. Three principles to consider when describing the baseline are as follows:

(1) In general, impacts attributable to the existence of the levees or to non-discretionary operations are incorporated within the impacts already in the environmental baseline rather than the effects attributable to the proposed action. The environmental baseline includes, not only the past and present impacts of existing structures over which the Corps lacks discretion, but also their continuing effects into the future.

(2) The Corps should clearly describe the scope of discretion over the proposed action and conduct a rigorous review to establish areas of non-discretion. The Corps bears a high burden of proof to demonstrate areas of non-discretion, and it is incumbent upon the Corps to demonstrate that it clearly lacks discretion over its activities.

(3) Where the scope of the Corps' discretion is not clear, effects should be attributed to the proposed action.

In general terms, the past, present, and future presence and effects associated with existing flood control structures should be included in the Environmental Baseline sections of the BA and biological opinion, and therefore not considered to be part of, or an effect of the Corps' proposed action. However, it can be difficult to clearly determine the difference between baseline conditions and a project's operational effects. Therefore, it is important for the Corps, to clearly define the boundaries of their discretion (or non-discretion) and to articulate specifically how the Corps is prohibited from taking action associated with the continued existence of flood control structures, and not simply that there is no specific authority. If it is not possible for the Corps to clearly separate these areas, then the Corps should attribute those effects to the proposed action.

Specific Section 7 Consultation Requirements

Section 7 consultation is initiated through a request that must include the following six pieces of information as described in CFR 402.14(c):

(1) A description of the proposed action to be covered;
(2) A description of the specific area that may be affected by the proposed action;
(3) A description of any listed species or critical habitat that may be affected by the proposed action;
(4) A description of the manner in which the action may affect any listed species or critical habitat, and an analysis of any direct, indirect, or cumulative effects;

   (a) Direct Effects: Effects to listed species of designated critical habitat that occur during implementation of the project;
   (b) Indirect Effects: Effects to listed species that occur later in time or offsite, but are reasonably certain to occur;
   (c) Cumulative Effects: For purposes of the ESA, cumulative effects are defined as the effects of future State or private activities, not involving Federal activities, that are reasonably certain to occur within an action area of the Federal action subject to consultation (50 CFR 402.02). Future Federal actions are not included here because they require separate consultation pursuant to Section 7 of the ESA;

(5) Relevant reports, including any environmental impact statements, environmental assessments, biological assessments or other analysis prepared regarding the proposal; and
(6) Any other relevant studies or other information available on the action, the affected listed species, or critical habitat.

In order to complete the consultation, the comments and questions presented below need to be addressed by the Corps. The comments and questions are presented numerically to correspond to the six "Specific Section 7 Consultation Requirements" that are presented above.

1. A description of the proposed action to be covered.

   a. The Corps should provide a more detailed presentation of the proposed setback levee located in element IVc than was given on page 18 (table 2), and on page 19. In particular, to aid with the effects analysis for this particular action, the BA should include: 1a

      i. The elevations of the newly "exposed" flood plains in the area of the setback levee;
      ii. The expected frequency of inundation during high water events.
      iii. The expected durations of inundation under different high water stages;
      iv. Potential for stranding in any depressions or perched areas within the setback levee area.

   b. The Corps should provide a better explanation in the BA as to why setback levees were not pursued in elements Va and VIa.1. Hydraulic modeling data should be presented to substantiate the claim that a setback levee would increase flood flows down the mainstem San Joaquin River under all potential setback levee designs in this location. If multiple setback levee scenarios were not modeled that could take advantage of the opportunities of a setback levee in this location, such modeling should be conducted. 1b
   c. The BA should clarify the roles of the San Joaquin Multi-species Habitat Conservation Plan implementation as to listed anadromous species under NMFS jurisdiction; none of NMFS' species are part of the plan, therefore any habitat mitigation implemented under the plan would need to consider our species separately. If the mitigation conducted under the plan does not benefit NMFS' species, this should be stated. If applicable, separate mitigation efforts should be clearly defined for NMFS' listed species. 1c
   d. The BA should clearly indicate which actions under the proposed Project will comply with the general work window stated on page 21 (July 1 through November 1) and which elements of the Project will be implemented outside of this work window. It appears that some Project elements are anticipated to be implemented outside this window as suggested by the request for work window variances from the Central Valley Flood Control Board (page 21). 1d

2. A description of the specific area that may be affected by the proposed action.
    a. The BA indicates that the action area will extend 15 miles away from the actual project area (page 29). This would include the waterways encompassed by essentially the entire South Delta (San Joaquin River mainstem between Lathrop and French Camp to Old River in the west near Discovery Bay and Clifton Court). If this is carried forward as the action area, then the environmental baseline, species occurrences, and project effects will have to be modified to correspond to this enlarged footprint, and the appropriate effects analysis conducted. 2a

3. A description of any listed species or critical habitat that may be affected by the proposed action.
    a. The BA should use the most current scientific and commercially available data in its status reviews of the species. The West Coast Region of NMFS has issued publically available 5-year status reviews for the listed Chinook salmon and steelhead populations in the Central Valley, as well as a 5-year status review for the southern DPS of green sturgeon. (available at: http://www.westcoast.fisheries.noaa.gov/publications/status_reviews/salmon_steelhead/2011_status_reviews_of_listed_salmon_steelhead.html and http://www.westcoast.fisheries.noaa.gov/protected_species/green_sturgeon/green_sturgeon_pg.html. 3a
    b. The status of the species should reference the final version of the Recovery Plan for Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, and California Central Valley steelhead issued in July 2014, rather than the draft Recovery Plan referenced in the BA. Available at: http://www.westcoast.fisheries.noaa.gov/protected_species/salmon_steelhead/recovery_planning_and_implementation/california_central_valley/california_central_valley_recovery_plan_documents.html. 3b
    c. The status of Central Valley spring-run Chinook salmon regarding the presence of this population in the San Joaquin River basin should be updated to reflect the current reintroduction efforts. Juvenile spring-run Chinook salmon have been released into the system for the past two years (2014 and 2015) with returns possibly occurring this year as 2-year old jills and jacks (2015) come back from the ocean. 3c
    d. The description of EFH for Pacific salmon has been updated and revised with Amendment 18 to the salmon fishery management plan (September 2014). Available at: http://www.pcouncil.org/salmon/fishery-management-plan/adoptedapproved-amendments/. The BA should reflect this revised material for Pacific salmon EFH. 3d

4. A description of the manner in which the action may affect any listed species or critical habitat, and an analysis of any direct, indirect, or cumulative effects.
    a. The construction related effects described in the BA for listed fish species is very cursory. The BA should explain in more detail the expected effects related to turbidity based on: 4a

i. Timing of construction and fish presence in the adjacent waterways will be different for each population of listed fish. Depending on which population of fish is moving through the action area, the effects will be different based on the co-occurrence of construction activities and fish presence. In some instances it will be direct effects, in others it will be indirect since construction and fish presence may not overlap with each other. 4a
ii. Indirect effects are likely to occur in the winter due to exposed soils carrying turbidity either directly into the adjacent waters, or via an indirect route as stormwater discharges into the adjacent receiving waters through outfalls.

b. The BA does not adequately describe the effects of contaminants on exposed fish that are discharged into the adjacent waterways. Contaminants are most likely to move into the adjacent waterways during precipitation events and will expose different life stages of fish based on the timing of the storms. The effects of the different classes of contaminants will have different toxicological and physiological effects on exposed fish. These effects need to be assessed in the BA. 4b
c. The effects of the setback levee on the different runs of listed fish as well as fall-run Chinook for EFH must be assessed. This should include at a minimum:

   i. Changes in growth rate for fish rearing on the floodplain.
   ii. Risk of predation from predators on the floodplain.
   iii. Risk of stranding during the high water recession phase. 4c
   iv. How frequently the floodplain becomes available to emigrating fish and for how long at different water elevations.
   v. Using the above information, an integration and synthesis of the variable effects of the setback levee should be performed which determines the net benefits to listed fish and fall-run Chinook salmon.

d. The BA does not adequately describe the indirect effects of enhanced levee safety on the induced growth of surrounding communities. On page 15 the BA indicates that implementing Phase 3 has the intent of "improving the existing levee integrity based on the new USACE standards and continue to provide flood risk reduction within RD 17 and the surrounding areas." By improving flood safety and meeting new Corps standards, the ability to get flood insurance is enhanced and existing and new homes yet to be built would benefit. This encourages further development in the RD 17 service area that may not occur if flood insurance was determined to be a riskier venture due to lessened levee safety. The BA should more fully explain the interaction between enhanced levee flood protection and regional growth patterns. 4d
e. The BA describes cumulative effects that are likely to occur in the future (*i.e.*, future housing developments related to different regional and local "General Plans") but fails to explain how these cumulative effects will affect aquatic species. The cumulative effects section of the BA describes how aspects of the 4e

Phase 3 activities will impact riparian habitat and water quality. That discussion would be more appropriate for the BA's Project effects section. The BA should explain how the housing developments and increases in human population would affect the aquatic and riparian habitats (*i.e.*, increase in traffic on area roadways, increases in impervious surfaces affecting storm runoff patterns, increases in urban and domestic contaminants, increased stormwater runoff volumes and discharge to surface waters, increased demand for drinking water, increased 4e production of sanitary waste water that requires treatment with eventual disposal, *etc.*). In examining these effects, the BA should conduct a separate analysis for listed species under NMFS' jurisdiction since the San Joaquin Multi-Species Conservation Plan does not include these species, and thus impacts to these species are not evaluated under that plan (see page 52 of BA) and would not undergo any federal review.

5. Relevant reports, including any environmental impact statements, environmental assessments, biological assessments or other analysis prepared regarding the proposal.
    a. The Corps should provide the Draft Environmental Impact Statement/ 5 Environmental Impact Report with this BA to help clarify details of the project that are referenced in the BA (*e.g.*, the setback levee analysis for the Project including any hydraulic analyses completed to date).

6. Any other relevant studies or other information available on the action, the affected listed species, or critical habitat.
    a. See above for inclusion of the best available scientific information regarding the 6 most recent 5-year species accounts and EFH information.
    b. Incorporate most recent species viability assessments conducted by NMFS for listed species in the Central Valley.
    c. Incorporate recent studies regarding steelhead and Chinook salmon survival through the lower San Joaquin using acoustic tags.

Essential Fish Habitat

The analysis of the effects of the proposed Project regarding impacts to EFH for Pacific salmon relies on the analysis described for impacts to fish and critical habitat. The analysis should examine how changes to the habitat essential features necessary to support the various life stages of Pacific salmon are altered and how this changes the survival of the Pacific salmon stocks exposed to the Project's effects to provide support for their determination on EFH effects. The Corps should explain how loss/gain of riparian habitat and SRA, and the armoring of river 7 shorelines would impact habitat that fish utilize for the different stages of their life history. For example, assessment of the loss of overhanging shaded canopy on local water temperatures, loss of input of organic materials with terrestrial origins (allochthonous input) on the functioning of the local food web, hydrodynamic and ecological effects of channel armoring which prevents formation of riparian benches, river sinuosity, and normal sediment budget in the impacted river reaches would be appropriate. This level of analysis is missing from the BA's assessment of Project impacts to EFH.

The ESA consultation process for this project will not be initiated until we receive all of the required information to initiate consultation, or a statement explaining why that information cannot be made available, and a written assessment of the effects of the action on EFH [50 CFR 600.920(g)(1)(2)]. Once we receive all of the information necessary to initiate and complete consultation, we will review it and contact you with a determination of our findings on this project.

If you have any questions or comments regarding this letter, please contact Jeffrey Stuart at (916) 930-3607 or via e-mail at J.Stuart@noaa.gov.

Sincerely,

Maria Rea
Assistant Regional Administrator
West Coast Region

Subject: Information Request for the Proposed Reclamation District 17 Phase 3 Levee Seepage Repair Project, San Joaquin County, California

Dear Ms. Kirchner:

This is in response to your February 27, 2015, letter requesting formal consultation with the U.S. Fish and Wildlife Service (Service) on the U.S. Army Corps of Engineers' (Corps) Reclamation District 17 (RD 17) Phase 3 Levee Seepage Repair Project, San Joaquin County, California. At issue are effects of the proposed project on the federally-listed as threatened valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) and endangered riparian brush rabbit (*Sylvalagus bachmani riparius*). The Service received your request on March 3, 2015. This 1
response is provided under the authority of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act).

The Biological Assessment (BA) which was provided with your request does not contain a level of detail sufficient to prepare a biological opinion and does not contain sufficient information necessary to initiate formal consultation as outlined in the regulations governing interagency consultations (50 CFR§ 402.14). In order to fully evaluate the potential effects to listed species as a result of the proposed project, the Service provides the following comments and information requests below:

1. Additional description of current and future water side maintenance: The proposed project consists of 5.3 miles of intermittent flood protection work on the right (east) bank levee of RD 17 involving land side seepage berms, conventional and deep slurry mixing cutoff walls, and
wetland fill. The BA provides a reasonable level of detail about the locations of the proposed 2
work and direct effects on habitat on the land side. However, the BA does not provide a sufficient description of the direct, cumulative, and/or indirect effects on habitat on the water side. The BA (p. 16) assumes that interim criteria established for determining eligibility for Public Law 84-99 means that the waterside vegetation would be managed in accordance with RD

17 existing practices after the proposed project is constructed. Those practices are described in 2 cont.
the BA as involving an allowance of some of the waterside vegetation to remain.

In the 2011 draft Environmental Impact Statement/Report on the proposed project, the Corps
stated that the future conditions of levee vegetation were uncertain and (p. 1-15) "....could be a
continuation of the Framework, full compliance with vegetation management guidelines in ETL 3
1110-2-571, or another approach." Compliance with ETL 1110-2-571 [superseded by ETL
1110-2-583, dated April 30, 2014], could involve seeking Corps permission to retain vegetation
on the lower two thirds of the waterside slope, however, this permission cannot be presumed.

The Corps should verify that it is consulting on the effect of both construction as well as
maintenance of the proposed project. The Corps should thoroughly describe and clarify the
current and future maintenance practices on the project levee. This should include a summary of
records of inspection and maintenance, and the areas affected, so that the frequency and extent of
the current maintenance can be confirmed, and a description of the maintenance practices 4
expected in the future with an analysis of potential effects to listed species. If future
maintenance practices change from what is described in the BA in a way that changes the effect
on a listed species, the Corps should reinitiate consultation with the Service (50 CFR§ 402.16).

2. <u>Additional analysis and justification on quantification of listed species habitat effects and
proposed compensation</u>: The Corps proposes to compensate for 3.28 acres of landside riparian
brush rabbit habitat loss with 4.52 acres of riparian habitat to be restored water side of a setback
levee to be constructed at element IVc. The 3.28 acres of loss are distributed between elements
IIIa-b and Va-VIa.1, a distance of several river miles, while the compensation is in a more
limited distance of about 0.4 river miles. Although some habitat would remain on the water side,
the amount of this remaining habitat was not quantified in the BA. Moreover, as described 5
above (#1), it is uncertain how much water side vegetation would remain dependent on the
prescribed maintenance, although it is apparent from the BA exhibits that some of the vegetation
is outside of any potential maintenance zone. The Corps should estimate the amount of habitat
not only in the construction footprint, but also in the near vicinity between the water edge
landward to 15 feet beyond the landside toe. This is well within the action area, which includes
all areas of direct and indirect effects. The requested information would allow the Service to
better evaluate the effect of the project and its maintenance on listed species.

The Service would consider the importance of the proposed setback levee and compensation area
at element IVc being within the project area where impact occurs. If the compensation is
successful and the habitat becomes occupied, it could benefit the riparian brush rabbit and reduce
the potential for local extirpation and reduction in range. However, the ratio of compensation to
impact for this site is only 1.3:1. This is a relatively modest ratio considering the known
sightings of riparian brush rabbit within or near habitat which would be lost due to the project, 6
the effect of the project on continuity of remaining habitat, and future cumulative effects that
would result from dense housing and commercial development behind the improved levee.
Some of the types of impact associated with these cumulative effects would include increased
disturbance from human use (e.g., trails, camping, fire), intensified maintenance practices, and
impact of non-native animals including escaped pets and pest rodents. Additionally, the
conversion of large tracts of agricultural and other non-urban lands may constrain dispersal of

the rabbit. Although management measures can be implemented to minimize these effects, they cannot be eliminated. Despite evidence of rabbit occupation as noted in BA Exhibit 15, the habitat in the project area is already severely fragmented. Thus, the persistence of the riparian brush rabbit cannot be presumed with the proposed project and compensation.

Compensation ratios of 3:1 or more as well as thorough management and monitoring (see #3, 6 cont.
below) are likely necessary to offset direct impacts under these circumstances. For example, a 3:1 ratio is specified in the current habitat conservation plan for San Joaquin County for non-wetland natural lands such as oak woodlands (Table 3-1 *in* San Joaquin County Multispecies Habitat Conservation and Open Space Plan, November 14, 2000). To achieve a higher ratio would involve additional compensation beyond that proposed, and the Service's preference for this would be to maximize opportunities on or near to the location of the effects before considering off-site options. The BA (pp. 28, 54) mentions that the local sponsor, RD 17, is studying options for additional off-site compensation but it does not provide specifics. We request the Corps provide a more detailed justification for its compensation proposal of 4.52 acres at element IVc only, and identify potential locations of additional compensation sites under consideration. If exact locations are not yet known, we request information in the form of at 7
least general areas and conceptual approaches (creation, enhancement, and protection) that are under consideration as off-site compensation.

It appears from the exhibits in the BA that the determination of affected riparian brush rabbit habitat was based on the dripline of woody species of plants identified in aerial imagery. Conversely, our initial inspection of BA Exhibit 12 (p. A-18) suggests that the compensation area includes gaps between plant (unless complete coverage by shrub was assumed). However, the riparian brush rabbit regularly forages in herbaceous/ruderal habitat near the riparian areas. 8
The rabbit would be expected to move regularly between riparian fragment areas that are closer together and occasionally over larger distances during dispersal movement. Therefore, additional information is also needed on how effects and compensation quantities were determined in the BA. The Corps should specify whether ruderal areas between nearby riparian shrubs were included or excluded from the effect area, and the method by which this determination was made.

3. <u>Additional information on management and monitoring</u>: The BA (p.28) refers to a proposal to develop a mitigation and monitoring plan specific to habitat restoration in association with element IVc and off-site compensatory habitat components. A moderate, additional level of specificity is needed on what measures would be included in this plan, the responsible parties, protections, and assurances of funding of implementation. Some of the elements of the plan 9
would include the planting design, irrigation, measureable objectives, monitoring of those objectives, and remedial measures in the case of any shortfall. Additional management elements may include the need to thin excess vegetation or remove non-natives, establishment of firebreaks, inspections, regular patrols for human activities, and monitoring of habitat and effects to listed species. The level of detail in the additional information should be sufficient to reasonably conclude that the 4.52-acre area at element IVc will achieve measureable objectives, and that it will have adequate oversight. The Corps should also state whether or not elderberry shrubs will be included in the mitigation plan for this site. 10

Some level of additional monitoring should also apply to all project phases, to verify that
maintenance practices needed to sustain project performance, do not adversely affect listed
species habitat, and that the effects of ongoing maintenance are within what has been analyzed
for the project. This will likely necessitate regular assessment and reporting of both riparian 11
habitat generally and elderberry plants specifically along the full length of RD 17 levees. The
Corps should consider this need and provide additional information on habitat monitoring after
the project is completed.

4. Additional information on future flood control projects: The BA (pp. 14-15) discusses the
need for the proposed project to address seepage issues to maintain accreditation for a 100-year
level of flood risk reduction. However, the State requires a 200-year level of protection for 12
urban or urbanizing areas. The Corps should provide additional information on whether there
are any other projects or actions, beyond the proposed project, which would be needed to attain
the 200-year level of protection. If so, the Corps should also state whether these other projects or
actions could affect listed species.

5. Additional information on on-site compensation opportunities: The BA (pp. 19-20) provides
a limited discussion of cost and hydraulic factors to justify exclusion of setback levees at various
locations as a means to provide compensatory habitat. In light of the already very sparse habitat
in the project area, the Service has a keen interest in improving the amount and continuity of this
habitat within the project area where possible. This could include setbacks of any dimension, as 13
well as enhancement of habitat in waterside areas outside the levee prism. Please provide more
detailed information on the exclusion of setbacks on the basis of cost or hydraulics. We also
request information on opportunities for enhancing and creating habitat within the existing
floodway in the project area through planting and management.

Until all of the above requested information is received, the Service cannot begin consultation on
the Reclamation District 17 Phase 3 Levee Seepage Repair Project. If you have any questions 14
regarding this response, please contact Steven Schoenberg, Senior Fish and Wildlife Biologist, at
(916) 414-6564.

Sincerely,

K. S. Turner

INTRODUCTION

This Conceptual Mitigation Monitoring Plan (Conceptual MMP) has been prepared for Phase 3 of the proposed Reclamation District 17 (RD 17) Levee Seepage Repair Project (LSRP) (Phase 3 Repair Project) (See the "Proposed Project Requiring Mitigation" section below for a brief summary of the previous Phase 1 and Phase 2 Repair Projects.) In order to issue a Biological Opinion for the Phase 3 Repair Project, the U.S. Fish and Wildlife Service (USFWS) requested more detailed information regarding habitat compensation for the riparian brush rabbit (*Sylvilagus bachmani riparius*). This Conceptual MMP is intended to provide that detail and to also describe mitigation for valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) (VELB). Specific design details are still in progress for the proposed Mitigation Site and will be provided to the USFWS and other regulatory agencies in a Final Mitigation Monitoring Plan (Final MMP).

This page intentionally left blank.

PROPOSED PROJECT REQUIRING MITIGATION

RD 17 is located in south-central San Joaquin County, California (**Exhibit 1**). The boundaries of RD 17 are marked by French Camp Slough on the north, approximately 3 miles southwest of the central business district of the City of Stockton; the San Joaquin River on the west; Walthall Slough on the south (just below State Route 120); and Airport Way/McKinley Avenue on the east, just outside the City of Manteca. RD 17 is responsible for levee operation and maintenance of over 19 miles of levees along Walthall Slough, the San Joaquin River, and French Camp Slough, as well as a dryland levee along the southern boundary of Manteca (**Exhibit 2**). These levees have been divided into 11 distinct "reaches" identified by Roman numerals (i.e., I, II, III…, XI), and subdivided further into "elements," identified by the reach number followed by a lowercase letter and, where needed to further distinguish elements, an Arabic numeral (e.g., Ia, IIa, IIb, …, Va, VIa.1, VIa.2, VIa.4, …, VIe, VIIa, VIIb, …, XIa) (**Exhibit 2**). Reaches VIII through XI, which make up the dryland levee, are not included in the USACE flood risk management project, and therefore not subject to 408 authorization. Further, the Phase 3 Repair Project does not include improvements to these dryland levee elements, and no permits under Section 404 would be required.

Since 2007, RD 17 has been undertaking the LSRP to increase the levee system's resistance to under seepage and through -seepage and bring RD 17's approximately 19-mile levee system into compliance with the new USACE seepage criteria. Phases 1 and 2 of the LSRP were completed in summer 2010. The purpose of the Phase 3 Repair Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.3 miles (along the San Joaquin River and Walthall Slough) of the approximately 19-mile RD 17 levee system to improve the existing levee integrity based on the new U.S. Army Corps of Engineers (USACE) standards and continue to provide flood risk reduction within RD 17 and surrounding areas. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation.

PROJECT DESCRIPTION

The Phase 3 Repair Project levee improvements would include seepage berms, chimney drains, cutoff walls, a setback levee, and a raised landside grade. **Table 1** briefly summarizes the activities proposed for each project element.

Table 1
Summary of Major Activities Proposed for Each Element

Element	Type of Remediation	Proposed Activities
Ia	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and install a 590-foot-long seepage berms (minimum 65 feet wide) with chimney drain to meet required exit gradients.
Ib	under seepage and through seepage	Fill existing depression to 300 feet from toe of existing levee; place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width; and install a 125-foot-long seepage berm (minimum 60 feet wide) with chimney drain on top of fill to meet required exit gradients.

Table 1 Summary of Major Activities Proposed for Each Element		
Element	**Type of Remediation**	**Proposed Activities**
Ie, IIIb, IVa, and VIIb	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and construct seepage berms with lengths of 655 feet (Ie), 720 feet (IIIb), 525 feet (IVa), and 385 feet (VIIb), and chimney drains to meet required exit gradients. Minimum seepage berm widths would vary (65–105 feet) depending on the element. For Element Ie, construct v-ditch from seepage berm to existing swale.
IIab	under seepage and through seepage	Install cutoff wall with a length of 2,550 feet to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.
IVc	under seepage and through seepage	Construct 1,240-foot-long setback levee with seepage berm and cutoff wall to meet required exit gradients. Depth of the cutoff wall will be 60 feet. Cutoff wall will involve degrading the top 1/3 to 1/2 of the levee crown and will begin with a 1:1 cut at the waterside crown. Seepage berm would be a minimum of 65 feet wide. Install riprap on waterside of existing levee above the high tide line where it would intersect setback levee. After setback levee is completed, remove 400 linear feet of the existing levee above the high tide line on downstream side of oxbow. Grade approximately 8 acres of setback area, to drain to the river through the downstream opening in the remnant levee, and restore approximately 11.5 acres of riparian scrub and Great Valley Valley Oak woodland in area between the landside toe of the setback levee and the river.
Va and VIa.1	under seepage and through seepage	Where feasible, place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and install cutoff walls with a length of 9,520 feet to meet required exit gradients. Depth of cutoff walls would vary from 60–85 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Open-cut method would be used for all cutoff walls.
IIIa	through seepage	Place levee fill material along landside of existing levee slopes where feasible to provide minimum 3:1 slopes and 20-foot levee crown widths and install chimney drain in existing 4,680-feet-long seepage berm to meet required exit gradients.
VIa.4	under seepage and through seepage	Install cutoff wall with length of 70 feet to meet required exit gradients. Depth of cutoff wall would vary from 90–100 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 26-foot levee crown width.
VIb and VIcde	under seepage and through seepage	Install cutoff wall with length of 3,720 feet (VIb and VIcde) to meet required exit gradients. Depth of cutoff wall would vary from 70–80 feet. Cutoff wall in levee prism would involve both deep slurry mix construction as well as degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown.
VIIe	under seepage and through seepage	Install cutoff wall with a length of 1,900 feet to meet required exit gradients. Depth of cutoff wall would vary from 60–120 feet. Deep slurry mixing method would be used. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width. Soil removed during levee degradation would be stockpiled on adjacent RD 17 property and used for rebuilding

Table 1 Summary of Major Activities Proposed for Each Element		
Element	**Type of Remediation**	**Proposed Activities**
		the levee at these locations or used for fill at other locations in the Phase 3 Repair Project.
VIIg	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and construct seepage berm with chimney drain with length 395 feet to meet required exit gradients. Minimum seepage berm width would be 65 feet.

PROJECT IMPACTS

This MMP addresses Phase 3 Repair Project impacts to potential habitat for riparian brush rabbit and VELB, as described below. The Phase 3 Repair Project will also require compensatory mitigation for permanent impacts to waters of the United States that are under the jurisdiction of the USACE and Regional Water Quality Control Board. A brief overview of these impacts and proposed mitigation are also provided. In addition to identified permanent impacts, the Final Environmental Impact Report (RD 17 *in prep*) and Final Environmental Impact Statement (USACE *in prep.)* for the Phase 3 Repair Project identify potentially significant impacts, and the mitigation measures that will be implemented to reduce those impacts to a less-than-significant level, for landside woodlands, special-status plants, fish, and other special-status wildlife species.

RIPARIAN BRUSH RABBIT

The Phase 3 Repair Project levee improvements would result in the removal of 3.28 acres of landside riparian habitat, specifically Great Valley cottonwood riparian forest and Great Valley Valley oak riparian forest, that is suitable for riparian brush rabbit (**Table 2; Exhibits 3a, 3b, 3c,**). This riparian habitat is located on the landside of the levee, where levee improvements (e.g., chimney drains, seepage berms) would be constructed. In general, most of the landside riparian vegetation is sparse and lacks understory vegetation other than grasses and ruderal vegetation, which would act as cover for riparian brush rabbit and is not suitable for this species (Hansen, pers. comm., 2011).

However, there is potential for some of these landside woody habitats to support suitable habitat for riparian brush rabbit, particularly because these are located adjacent to waterside riparian habitats that either are known to be occupied by this species or are highly suitable habitat. All landside riparian habitat was considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied or highly suitable for riparian brush rabbit (i.e., Element IIab through Element VIe; **Exhibit 4a, 4b, 4c, and 5**). North of Element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., Elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species. No waterside woody or riparian habitat would be removed as a result of levee improvement activities.

Table 2 Phase 3 Repair Project Impacts on Suitable Riparian Brush Rabbit Habitats	
	Acres of Directly Affected Suitable Habitat[1,2]
Waterside woodlands	0.00
Landside woodlands	3.28
TOTAL	3.28

Notes:

[1] Suitable riparian brush rabbit habitats are characterized as Great Valley cottonwood riparian forest and Great Valley Valley oak riparian forest.

[2] Most of the landside riparian vegetation is sparse and lacks understory and is not suitable for this species (Hansen, pers. comm., 2011). However, any landside riparian habitat was considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied by or highly suitable for riparian brush rabbit (i.e., Element IIab through Element VIe). North of Element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., Elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.

Source: Data compiled by AECOM in 2014

Nearly 54 acres of ruderal annual grassland would also be affected by Phase 3 Repair Project implementation. All effects on ruderal annual grassland that would result from levee improvements are assumed to be temporary because annual grassland would be reestablished in these areas after project completion. Although riparian brush rabbit may use annual grassland as foraging habitat, the key component of habitat suitability for this species in the Phase 3 Repair Project area is based on the presence of riparian woody vegetation, and not the surrounding grasslands. Riparian brush rabbits forage along the edges of shrub cover and in small clearings in the vegetation cover, rather than in large openings, feeding on herbaceous vegetation such as grasses, sedges, clover, forbs, buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). Further, because this species is known to have a small home range and seldom ventures more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006), the riparian brush rabbit likely uses only a small component of the grassland and its use of such habitat is concentrated along the edges of the riparian areas.

The loss of potential riparian brush rabbit habitat in the Phase 3 Repair Project area could restrict the range of this species because the RD 17 area currently contains the northernmost known extent of the population on the San Joaquin River. It also could isolate other populations residing in residual habitats in the project vicinity. An overview of the proposed mitigation is described below under the “Mitigation Site Overview, Goals, and Objectives” section.

VALLEY ELDERBERRY LONGHORN BEETLE

Eighteen elderberry shrubs are present in or adjacent to the footprint of the Phase 3 Repair Project (**Exhibit 6**). The nine elderberry shrubs located along the waterside of the Phase 3 Repair Project levees would be avoided and protected during construction. The nine elderberry shrubs located along the landside of the levee would require removal to accommodate construction of the Phase 3 Repair Project’s seepage berms, and setback levee (**Table 3**). However, one of these landside shrubs does not have stems greater than one inch in diameter at ground level; therefore, it is not considered suitable VELB habitat. Compensation for removal of these stems 1 inch or greater in diameter at ground level will be provided in accordance with the USFWS *Conservation Guidelines for the Valley Elderberry Longhorn Beetle* (VELB Guidelines) (USFWS 1999) through planting at the Mitigation Site and/or purchase of habitat conservation credits from the French Camp Conservation Bank to offset the potential impacts from transplanting elderberry shrubs. An overview of the proposed mitigation is described below under the “Mitigation Site Overview, Goals, and Objectives” section.

Table 3 Survey Results for Landside Elderberry Shrubs that Would be Removed from the Phase 3 Repair Project Area					
Shrub Number	Number of Stems per Diameter Category (inches)			Beetle Exit Holes Present?	Riparian?[1]
	≥ 1 and ≤ 3	≥ 3 and ≤ 5	≥ 5		
9	0	0	0	No	No

OTHER PROJECT IMPACTS NOT COVERED IN THIS MITIGATION MONITORING PLAN

Jurisdictional Wetlands and Waters

The Phase 3 Repair Project would result in the permanent loss of approximately 0.55 acre of freshwater marsh at Element Ib because of seepage berm installation and approximately 0.22 acre of agricultural ditches at Elements Ie, IVa, and Va-IVa.1 because of seepage berm installation and re-grading of the existing levee (**Table 4**). To provide compensatory mitigation for the unavoidable impacts to 0.77 acre of waters of the United States, RD 17 will purchase credits at a mitigation bank, at a ratio determined by the USACE in collaboration with RD 17. RD 17 has identified the Cosumnes Floodplain Mitigation Bank as having availability and being within the service area to accommodate the RD 17 Phase 3 Repair Project.

Table 4 Estimated Impacts of the Phase 3 Repair Project on Jurisdictional Waters of the United States and Waters of the State	
Sensitive Habitat/Community	Permanent Impact (acres)
Freshwater wetland	0.55
Agricultural/Drainage Ditches	0.22
Total	**0.77**

Source: Data compiled by AECOM in 2014

MITIGATION SITE OVERVIEW, GOALS, AND OBJECTIVES

Compensatory mitigation for permanent impacts to potential habitat for riparian brush rabbit and elderberry shrubs suitable for VELB will be provided within the levee setback area in Element IVc. The new levee would be set back approximately 700 feet east of the existing levee footprint, providing approximately 11.3 acres of habitat for riparian brush rabbit and VELB, including approximately 3.9 acres of Great Valley Valley Oak woodland, 7.4 acres of Great Valley riparian scrub. The setback would also include a 0.4 acre floodplain swale (**Exhibit 7**). Approximately 1.4 acres is included as contingency; a minimum of 3:1 restoration-to-impact mitigation ratio to offset impacts to riparian brush rabbit habitat will be accomplished at the Mitigation Site (**Table 2**). The expansion and restoration of riparian habitat in Element IVc would augment the waterside riparian corridor along the San Joaquin River and provide additional riparian habitat for the riparian brush rabbit between two known occurrences of this species (i.e., between Elements IIIa/IIIb and Elements VIa.1/VIa.4 [CNDDB 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004], **Exhibit 5**).

Along the north side of the levee setback area, a section of the existing levee will be removed after certification of the new setback levee. The levee breach will allow floodplain inundation within the setback area. To avoid fish stranding within the setback area, the setback area will be graded to drain toward the levee breach inlet, and a fish release swale will be constructed at the base elevation of the setback area. The fish release swale will not be permanently inundated and will not be connected to the San Joaquin River during the dry season. The elevation of the levee breach inlet is still under consideration based on site constraints, habitat requirements and balancing the needs of riparian brush rabbit to provide protection to any individuals during high water events, while providing a level of disturbance that would potentially support scrub habitat in a sustainable way. It is anticipated that the floodplain swale would be set at an elevation to inundate approximately every 3 to 4 years and the lower floodplain approximately every 6 years. Setback area grading will transition from the fish swale sloping up gently to the west. The lower floodplain would be limited in size and would transition to a larger upper floodplain bench that would provide habitat during inundation. The existing levee will serve as high ground refugia during any extreme flooding events.

Native riparian scrub vegetation will be established within the entire setback area floodplain. Species in the plant palette will be those preferred by the riparian brush rabbit as providing cover including: California blackberry (*Rubus ursinus*), California wild rose (*Rosa californica*), sandbar willow (*Salix exigua*), coyote brush (*Baccharis pilularis*), and golden currant (*Ribes aureum*), among others (Kelly et.al. 2011). Understory vegetation would include herbaceous species that have been identified as preferred forage by the riparian brush rabbit such as mugwort (*Artemisia douglasiana*), and gumplant (*Grindelia camporum*). To provide refugia during flood events, the old levee footprint would also be vegetated with riparian scrub and riparian woodland tree species. The upland refugia will include elderberry seedlings and associated species plantings to mitigate for the impacts to VELB habitat within the Project site. In addition to plantings within the setback area, waterside riparian vegetation would be enhanced and open areas planted.

The primary goal of the habitat creation and enhancement at the Mitigation Site is to fully compensate for the loss of habitat for riparian brush rabbit and VELB resulting from construction activities associated with the Phase 3 Repair Project by providing self-sustaining habitat in perpetuity for these species. The following are specific objectives associated with the mitigation site:

- Reconnect and restore historic floodplain habitat on the San Joaquin River within the approximately 7-acre levee setback area at Element IVc by breaching the existing levee.
- Establish at least 9.9 acres of self-sustaining Great Valley riparian scrub and Great Valley Valley oak woodland habitat to provide compensatory mitigation for Phase 3 Repair Project impacts on 3.28 acres of potential habitat for riparian brush rabbit at a 3:1 mitigation ratio.
- Vegetate the existing levee to provide densely planted high ground refugia for riparian brush rabbits during high water events.
- Incorporate elderberry transplants from the Phase 3 Repair Project impact footprint into the Great Valley Valley oak woodland habitat.

- Establish 367 elderberry seedlings and 367 associate plantings within the Great Valley Valley oak woodland habitat to provide compensatory mitigation for the removal of 9 elderberry shrubs within the Phase 3 Repair Project impact footprint that provide potential habitat for VELB.
- Prevent fish stranding within the Mitigation Site by grading the site to drain back to the San Joaquin River and include a fish release swale in the Mitigation Site.
- Protect the Mitigation Site in perpetuity with deed restrictions, a conservation easement, or similar preservation mechanism acceptable to USFWS.

COMPENSATORY MITIGATION DESCRIPTION

MITIGATION SITE BASELINE CONDITIONS

As described above, the Mitigation Site is located within the setback levee in Element IVc (**Exhibit 3b**) within the City of Lathrop. The horseshoe-shaped site is directly adjacent to the San Joaquin River on the north, west, and south. Directly east of the Mitigation Site will be the newly constructed setback levee.

TOPOGRAPHY AND LAND USE

The only significant topographic relief within the Mitigation Site is provided by the existing levee with a crown elevation of 30 feet above mean sea level. Slopes on either side of the levee are generally 2H:1V. On the landside, this slope becomes more gradual moving east down to an elevation of 12 feet. On the waterside, on the north side of the setback area, slopes become more gradual to the water's edge, and on the south side, after an initial break in slope adjacent to the levee crown, slopes remain steep down to the water.

The site is located west of a residential development and associated park facilities that were constructed in 2004. The existing levee prism, maintenance road, and an approximately 50-foot-wide berm east of the levee have been generally maintained clear of vegetation. Prior to 2004, the basin protected by the levees and areas north, south, and east of the Mitigation Site were in agricultural production. Since 2004, the basin has been periodically maintained by disking, but is not under agricultural production. Areas north and south of the Mitigation Site remain in agriculture.

GEOLOGY

The Mitigation Site is located within the Great Valley Geomorphic Province of California, within the San Joaquin River Valley. Sediments in the Great Valley vary between 3 and 6 miles in thickness and were derived primarily from erosion of the Sierra Nevada to the east, with lesser amounts of material from the Coast Ranges to the west (USACE and RD 17 2011). Geologic formations at the Mitigation Site are mapped as part of the Dos Palos Formation (Wagner et. al. 1991). This formation consists of Holocene alluvial deposits of unweathered, unconsolidated arkosic gravel, sand, silt, and clay, covering the flood basin of the lower San Joaquin River. The Dos Palos Formation generally occurs in a northwest-trending belt in the San Joaquin Valley between the Coast Range and Sierra Nevada alluvial fans. The arkosic composition of this formation indicates that the sediments originated from plutonic rocks of the Sierra Nevada and were deposited during overflow and channel migration of the San Joaquin River and associated sloughs (Lettis 1982:128-131).

No active faults have been mapped within the Mitigation Site (Jennings 1994), and it is not located in an Alquist-Priolo Earthquake Fault Zone (California Geological Survey 2007; Hart and Bryant 1999).

SOILS

The only soil map unit that occurs within the Mitigation Site is classified as (130) Columbia fine sandy loam, drained, 0-2 percent slopes. **Table 5** summarizes information on this soil map unit, and provides a brief description of the soil series according to the Soil Survey of San Joaquin County (NRCS 2015).

Table 5 Soil Map Units that Occur within the RD 17 Mitigation Site					
Name	**Map Unit**	**Soil Series**	**Taxonomic Class**	**Description**	**Hydric**
Columbia fine sandy loam, drained, 0 to 2 percent slopes	130	Columbia	Coarse-loamy, mixed, nonacid, thermic Aquic Xerofluvents	Very deep, artificially drained soils formed on somewhat poorly drained alluvium derived from mixed rock sources. Found on natural levees on low floodplains along rivers. It is considered prime farmland if irrigated. The depth to water table is more than 80 inches. Permeability is high and available water capacity is low.	Yes
Source: NRCS 2015					

Prior to mitigation implementation, soil fertility samples will be collected from the Mitigation Site to assess soil chemistry and fertility and, if necessary, make recommendations for any soil amendments that may need to be incorporated prior to habitat restoration.

HYDROLOGY

Hydrology at the Mitigation Site is influenced by surface water and groundwater. The new setback levee would restrict overland flow to the Mitigation Site from the east. Thus, surface water inputs at the Mitigation Site would be direct precipitation, and input from the levee breach inlet on the San Joaquin River on the south side of the setback area during higher flows. Groundwater at the Mitigation Site is closely correlated to the adjacent San Joaquin River. Surface water and groundwater hydrology at the Mitigation Site are described in more detail below.

Surface Water Hydrology

The Mitigation Site is located in the southeastern portion of the Sacramento-San Joaquin Delta (Delta) directly adjacent to the San Joaquin River, the only aquatic resource feature within or adjacent to the site. Located between River Mile (RM) 53 and 52, the Mitigation Site is immediately downstream of Old River, and approximately 5 miles downstream of the Paradise Cut Bypass. Precipitation in the Mitigation Site occurs primarily during the months of November through March, with an average annual precipitation of approximately 12 inches.

The San Joaquin River originates in the Sierra Nevada and enters the San Joaquin Valley at Friant Dam. Most of the flow in the lower San Joaquin River is derived from inflow from the Merced, Tuolumne, and Stanislaus Rivers (Northeastern San Joaquin County Groundwater Banking Authority 2004). The river has flows ranging from 1,500 cubic feet per second (cfs) in dry years to more than 40,000 cfs in wet years (Friant Water Users Authority and Natural Resources Defense Council 2002). In most years, the San Joaquin River contributes approximately 15 percent of inflow to the Delta; the Sacramento River contributes roughly 75–80 percent; and the Mokelumne, Cosumnes, and Calaveras Rivers, which flow into the eastern side of the Delta, contribute the remainder (Delta Protection Commission 2000).

Hydrologic conditions in the San Joaquin River basin are dominated by snowmelt from the Sierra Nevada. Before major water storage projects were completed on the San Joaquin River and its major tributaries, lower San Joaquin River flows generally peaked in late spring/early summer and dropped to low levels in the fall. Since the completion of Friant Dam (1944), McClure Reservoir (1967 on the Merced River), Don Pedro Reservoir (1971 on the Tuolumne River), and New Melones Reservoir (1979 on the Stanislaus River), the lower San Joaquin River's seasonal flow pattern has changed substantially. Before 1944, based on 1923–1944 records, flow in the lower San Joaquin River tended to peak in May and June, with an average monthly flow of almost 11,000 cfs, and declined rapidly to an average monthly flow of approximately 1,200–1,300 cfs in August and September. Since 1979, the average monthly flow has peaked in March at just over 10,000 cfs, with a more gradual decline to approximately 2,400 cfs in August.

The lower reaches of the San Joaquin River are also influenced by tidal regime. Tidal fluctuation in the San Joaquin River extends to the Vernalis tide gage and the Airport Way crossing of the San Joaquin River, approximately 13 river miles upstream of the Mitigation Site.

Near the Mitigation Site, the San Joaquin River is characterized as a wide channel (approximately 200 feet) with little riparian canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. Altered flow regimes, flood risk management, and bank protection efforts along much of the San Joaquin River have reduced riparian vegetation and associated shaded riverine aquatic habitat, sediment transport, channel migration and avulsion, and large woody debris recruitment, and have isolated the channel from its floodplain.

Site Specific Surface Water Hydrology

An evaluation of Mitigation Site inundation frequency and duration based on the invert elevation of the levee breach was conducted by MBK Engineers (Appendix B). Frequency and duration of inundation was evaluated at three breach invert elevations: 8 feet (NAVD88), 10 feet (NAVD88) and 14 feet (NAVD88). Based on the hydraulic model analysis, the estimated flow at the location of the San Joaquin River near Vernalis U.S. Geological Survey (USGS) stream gage (Vernalis gage), about 17.5 miles upstream of the project area, at which water would enter the setback area through the remnant levee breach for the three breach invert elevations is shown in **Table 6**. Also included in **Table 6** are: an estimate of the return interval of the Vernalis flow, from a HEC-SSP Bulletin 17b analysis of the Vernalis gage record; and the corresponding computed flow in the San Joaquin River at the Mitigation Site.

Table 6
Estimated Flows for Inundation of the Mitigation Site

Breach Invert Elevation (feet, NAVD88)	Flow in San Joaquin River near Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Estimated Return Interval	Flow in San Joaquin River at Breach Location (cfs)
8	9,500	2 year	4,200
10	13,200	3 to 4 year	5,700
14	24,000	6 year	8,800

Note: cfs = cubic feet per second
Source: MBK Engineers 2016

To evaluate how often and how long the Mitigation Site would be expected to inundate, a review was made of the historical San Vernalis gage daily flow records since the completion of New Melones Dam in 1979; this represents a period where the San Joaquin River basin operating regime has been relatively unchanged. The evaluation used the mean daily flows for the period October 1, 1978, through September 30, 2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. **Table 7** summarizes the estimated number and percent of days in the evaluation study period in which the Mitigation Site would flood under different breach inverts.

Table 7 Estimated Total Duration of Mitigation Site Flooding for Evaluation Period of Record			
Breach Invert Elevation (feet, NAVD88)	San Joaquin River Flow at Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Number of Days Flow Equaled or Exceeded Since 10/1/1978	Percent of Days Flow Equaled or Exceeded Since 10/1/1978
8	9,500	1,619	12%
10	13,200	1,126	8.3%
14	24,000	423	3.1%
Note: cfs = cubic feet per second Source: MBK Engineers 2016			

A detailed table providing the estimated number of days in each water year that the Mitigation Site would flood for each of the three breach invert elevations, along with estimates of average and maximum depths of flooding in each water year is provided in **Appendix B**. The depths were computed relative to the breach invert elevation. Estimating the depth in the setback area was done with a two-step process:

1. Development of a regression correlation between the mean daily flow gage record at Vernalis and the mean daily stage at the California Department of Water Resources' San Joaquin River below Old River near Lathrop gage (Lathrop gage). This relationship was used to estimate a mean daily stage at the Lathrop gage based on mean daily flow at Vernalis. This was necessary because the Lathrop gage record starts in 2002.

2. Development of regression correlation between the stage at the Lathrop gage and the stage at the remnant levee breach. This relationship was derived from hydraulic model-computed data. It was used to translate the estimated stage at the Lathrop gage from step 1 to the remnant levee breach location.

A chronological plot of the Vernalis mean daily flow for the evaluation period of record is provided in **Appendix B** (Figures 1 and 2). Also indicated on these figures are the Mitigation Site flooding thresholds for each of the breach invert elevations.

Groundwater Hydrology

The groundwater basin at the Mitigation Site is within the Delta subregion, a part of the Central Valley aquifer system. Within this basin, the San Joaquin River divides the Tracy Subbasin to the west and the San Joaquin Subbasin to the east. Most of the fresh groundwater is unconfined (i.e., not bounded by an impermeable or less permeable confining geologic formation) and occurs at depths of less than 2,500 feet (DWR 2006:169–170). The shallower aquifers are used as sources of freshwater. Groundwater levels in the Mitigation Site generally are very shallow because of the low elevation and proximity to the San Joaquin River channel. High groundwater levels can be influenced by the water level in the river, subsurface groundwater flow from areas of higher elevation to the east, and local irrigation practices.

VEGETATION AND SENSITIVE HABITATS

Vegetation and land cover types within the Mitigation Site include remnant Great Valley cottonwood riparian forest, ruderal, and developed (i.e., the levee road) (**Exhibit 4b**). Relative to the dense riparian forest that once flanked the San Joaquin River in this reach, the community today consists of linear areas and occasional remnant patches of riparian forest and related riparian scrub that grow at the water's edge, outside of the levee maintenance zone. The waterside edge of the Mitigation Site consists of rip-rap along the southern half of the San Joaquin east levee and patchy remnant Great Valley cottonwood riparian forest and Great Valley riparian scrub along the northern half of the levee. Areas directly upslope of the rip-rap, along the levee slopes, and within the setback are dominated by ruderal vegetation. Beyond the base of the levees on the landside, there is a small isolated patch of remnant riparian vegetation.

Most of the Great Valley cottonwood riparian forest community could also be characterized as Great Valley riparian scrub, which does not include Fremont cottonwood and is characterized by a shorter canopy and more uniform structure; however, this habitat is part of the Great Valley cottonwood riparian forest that was extensive and connected along this entire reach of the San Joaquin River. Therefore, this document describes all riparian habitat as Great Valley cottonwood riparian forest community. Remnant patches of Great Valley cottonwood riparian forest within the Mitigation Site are dominated by large Fremont cottonwood (*Populus fremontii*) trees and Goodding's willow (*Salix gooddingii*~~*i*~~). Most of the otherwise linear or smaller patchy areas of this community lack Fremont cottonwood and are represented by Goodding's willow, arroyo willow (*S. lasiolepis*), narrow leaved-willow (*S. exigua*), and scattered valley oak (*Quercus lobata*), Oregon ash (*Fraxinus* latifolia), and buttonbush (*Cephalanthus occidentalis*). Native ground cover species, mainly found in the larger remnant patches of riparian forest, include California blackberry and wild rose. Common nonnative understory species found in most elements include Himalayan blackberry (*Rubus discolor*) and tree tobacco (*Nicotina glauca*).

Ruderal vegetation is characterized by nonnative weedy and sometimes invasive vegetation and nonnative annual grasses. Common weed species include yellow star-thistle (*Centaurea solstitialis*), black mustard (*Brassica nigra*), shortpod mustard (*Hirschfeldia incana*), Italian thistle (*Carduus pycnocephalus*), milk thistle (*Silybum marianum*), and Himalayan blackberry; common grass species include ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum* ssp. *leporinum*), Bermuda grass (*Cynodon dactylon*), and Johnsongrass (*Sorghum halepense*).

SPECIAL-STATUS SPECIES

Special-status Plant Species

Of the 18 special-status plant species that were evaluated for their potential to occur in the Phase 3 Repair Project area, five were identified with potential to occur within the Mitigation Site (**Table 8**).

Table 8
Special-Status Plant Species with Potential to Occur in the Element IVc Mitigation Site

Species	Status[1]	Habitat	Potential for Occurrence[2]
Slough thistle *Cirsium crassicaule*	CRPR: 2	Freshwater marsh, riparian scrub, chenopod scrub, along sloughs and riverbanks	Unlikely to occur in low-quality freshwater marsh habitat; last recorded in 1933 near San Joaquin River-Old River confluence, not confirmed in subsequent 1974 surveys; thought to be possibly extirpated
Delta button celery *Eryngium racemosum*	CRPR: 1B State: E	Freshwater and brackish marshes, riparian scrub, tidal zones in mud or silt soil	Unlikely to occur in low-quality freshwater marsh habitat; 1892 and 1913 herbarium records are only source of occurrences (near San Joaquin River and I-5 crossing); thought to be possibly extirpated
Sanford's arrowhead *Sagittaria sanfordii*	CRPR: 1B	Freshwater ponds, marshes and ditches	Unlikely to occur in low-quality freshwater marsh habitat; last recorded in 1901 at an unknown location near the City of Stockton
Suisun marsh aster *Symphyotrichum lentum*	CRPR: 1B	Freshwater and brackish marshes and sloughs	Unlikely to occur in low-quality freshwater marsh habitat; 1892 (near City of Lathrop) and 1920 (near town of Banta) herbarium records are only source of occurrences
Wright's trichocoronis *Trichocoronis wrightii* var. *wrightii*	CRPR: 2	Freshwater marshes and swamps, riparian woodlands	Unlikely to occur in low-quality freshwater marsh habitat; herbarium records from 1892 to 1914 are only source of occurrences (near San Joaquin River and I-5 crossing)

Table 8
Special-Status Plant Species with Potential to Occur in the Element IVc Mitigation Site

Species	Status[1]	Habitat	Potential for Occurrence[2]

[1] Legal Status Definitions
California Department of Fish and Wildlife State Listing Categories
E Endangered (legally protected)
CRPR California Rare Plant Ranking
CRPR Categories
1B Plant species considered rare or endangered in California and elsewhere (but not legally protected under the federal or California Endangered Species Acts
2 Plant species considered rare or endangered in California but more common elsewhere (but not legally protected under the federal or California Endangered Species Acts)

[2] Potential for Occurrence Definitions
Unlikely to occur: Potentially suitable habitat present but species unlikely to be present on the project site because of current status of the species, poor quality of available habitat, and/or very restricted distribution
Could occur: Suitable habitat is available at the project site; however, few or no other indicators show that the species may be present
Likely to occur: Habitat conditions, behavior of the species, known occurrences in the project vicinity, or other factors indicate a relatively high likelihood that the species would occur at the project site
Known to occur: The species, or evidence of its presence, was observed at the project site during reconnaissance-level surveys or was reported by others

Sources: CNPS 2014; CNDDB 2014; USFWS 2014; Hickman 1993; data compiled by AECOM in 2014, and revised by GEI Consultants, Inc. in 2016

Three of these species were identified from documented California Natural Diversity Database (CNDDB) (CNDDB 2014) occurrences within a 2-mile radius of the Mitigation Site: Delta button celery (*Eryngium racemosum*), Wright's trichocoronis (*Trichocoronis wrightii* var. *wrightii*), and slough thistle (*Cirsium crassicaule*). Two additional species occurrences were identified from California Rare Plant Rank (CRPR) Inventory (CNPS 2014) within the Lathrop USGS 7.5-minute quadrangles, which contains the Mitigation Site: Suisun marsh aster (*Symphyotrichum lentum*) and Sanford's arrowhead (*Sagittaria sanfordii*). A search of the USFWS endangered species database for these USGS quadrangles produced no additional special-status plant species (USFWS 2014). **Table 6** lists each special-status plant species along with its regulatory, CRPR, or San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) listing and CRPR status, its habitat requirements, and information related to each species' potential to occur in the Mitigation Site. All five special-status species are unlikely to occur because of the low-quality habitat found within the Mitigation Site; however, because the species could occur in freshwater marsh or riparian habitat along the San Joaquin River, their potential to occur in similar habitats within the Mitigation Site cannot be completely ruled out.

Special-status Wildlife Species

A total of 13 special-status wildlife species are known to occur or were evaluated for their potential to occur in the Phase 3 Repair Project area. Six of these species were documented from CNDDB (2014) occurrences within a 2-mile radius of the Phase 3 Repair Project area and from the CNDDB occurrences within the Lathrop USGS 7.5-minute quadrangle. Seven additional species were added based on a review of existing environmental documents, their coverage under the SJMSCP, and their potential to occur in habitats similar to those found within or adjacent to the Mitigation Site. A search of the USFWS endangered species database did not produce any additional special-status wildlife species (USFWS 2016).

Four of these species are Federally-listed or State-listed as threatened or endangered: VELB, Swainson's hawk (*Buteo swainsoni*), California tiger salamander (*Ambystoma californiense*), and riparian brush rabbit. The remaining species are California Species of Special Concern. **Table 9** summarizes the regulatory listing status, including coverage in the SJMSCP for each species, as well as their habitat requirements and the potential for them to occur in or adjacent to the Mitigation Site.

There is no designated critical habitat for special-status wildlife within or adjacent to the Mitigation Site.

Table 9 Special-Status Wildlife Species with Potential to Occur in the Element IVc Mitigation Site Area			
Species	**Status**	**Habitat**	**Potential for Occurrence**
Invertebrates			
Vernal pool fairy shrimp *Branchinecta lynchii*	Federal: T	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present within the Mitigation Site.
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	Federal: T	Inhabits elderberry shrubs, primarily in riparian woodland and scrub habitat	Known to occur; elderberry shrubs present occasionally along San Joaquin River on the waterside and landside of the levee in and adjacent to the Mitigation Site.
Vernal pool tadpole shrimp *Lepidurus packardi*	Federal: E	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present within the Mitigation Site.
Amphibians and Reptiles			
California tiger salamander *Ambystoma californiense*	Federal: T State: T	Winter: breeds in vernal pools and stock ponds that are fish-free and inundated for a minimum of 12 weeks; Summer: aestivates in rodent borrows in grassland habitat	No potential to occur. No suitable habitat is present within the Mitigation Site.
Northwestern pond turtle *Actinemys marmorata marmorata*	State: SSC	Ponds, marshes, rivers, streams, sloughs; nest in nearby uplands with suitable soils	Could occur; suitable habitat is present in backwater areas of the adjacent San Joaquin River.
California red-legged frog *Rana draytonii (=R. aurora draytonii)*	Federal: T State: SSC	Prefers semi-permanent and permanent stream pools, ponds, and creeks with emergent riparian vegetation and typically without predatory fish. Requires adequate hibernacula such as small-mammal burrows and moist leaf litter.	No potential to occur. No suitable habitat is present within the Mitigation Site.
Reptiles			
Giant garter snake *Thamnophis gigas*	Federal: T State: T	Streams, sloughs, ponds, and irrigation/drainage ditches; also requires upland refugia not subject to flooding during the snake's inactive season.	No potential to occur. No suitable habitat is present within the Mitigation Site.
Birds			
Tricolored blackbird *Agelaius tricolor*	State: SSC	Nests in dense cattails and tules, riparian scrub, and other low, dense vegetation; forages in grasslands and agricultural fields	Unlikely to occur; foraging habitat present in adjacent areas, but nesting is not expected because of low-quality habitat; closest nesting colony is approximately 3 miles southeast of the Mitigation Site along Yosemite Avenue in large area of giant reed with no water.
Burrowing owl *Athene cunicularia*	State: SSC	Nests and forages in grasslands, shrublands, and agricultural fields, especially where ground squirrel or other mammal burrows are present	Could occur; suitable foraging and nesting habitat present in adjacent areas; but no occurrences are documented in the Phase 3 Repair Project area or Mitigation Site.
Swainson's hawk *Buteo swainsoni*	State: T	Nests in riparian woodlands and isolated trees; forages in grasslands, shrublands, and agricultural fields	Known to occur; suitable foraging habitat and nesting habitat present in and adjacent to the Mitigation Site.

Table 9 Special-Status Wildlife Species with Potential to Occur in the Element IVc Mitigation Site Area			
Species	**Status**	**Habitat**	**Potential for Occurrence**
Northern harrier *Circus cyanus*	State: SSC	Nests and forages in a variety of open habitats, including marshes, grasslands, shrublands, and agricultural fields	Could occur; suitable foraging and nesting habitat present in and adjacent to the Mitigation Site.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	Federal: T	Insect-feeder that forages in dense riparian oak forest canopy along major rivers. Species is considered extirpated from San Joaquin County.	Unlikely to occur. Although potential dispersal and foraging habitat is in the Mitigation Site is outside of the species' extant range.
White-tailed kite *Elanus leucurus*	State: FP	Nests in woodlands and isolated trees; forages in grasslands, shrublands, and agricultural fields	Could occur; suitable foraging and nesting habitat present in and adjacent to the Mitigation Site.
Song sparrow (Modesto population) *Melospiza melodia*	State: SSC	Nests in emergent freshwater marshes and riparian forests with dense understory	Could occur; suitable foraging and nesting habitat present; but no occurrences are documented in the Mitigation Site.
Least Bell's vireo *Vireo bellii pusillus*	Federal: E	Nests in riparian habitat adjacent to riverine and freshwater marsh.	Unlikely to occur. Although suitable habitat is present, the last recorded observation of this species in the action area was in 1878, with no extant occurrences.
Yellow-headed blackbird *Xanthocephalus xanthocephalus*	State: SSC	Nests in freshwater wetlands with dense vegetation and deep water, often along borders of lakes and ponds and where large insects are abundant	Unlikely to occur; 1894 museum collection record from Lathrop area is only occurrence data.
Mammals			
Riparian brush rabbit *Sylvilagus bachmani riparius*	Federal: E State: E	Inhabits riparian forest with dense understory	Known to occur; occupied riparian habitat is present on the waterside of Elements IIIa and IIIb just north of the Mitigation Site; also known to occur on an oxbow south of the Mitigation Site between Elements VIa.1 and VIa.4.
Western mastiff bat *Eumops perotis californicus*	State: SSC	Wide variety of habitats; roosts primarily in crevices on cliff faces and boulders but occasionally in old buildings	Could occur; suitable foraging habitat present, but no potential roost sites.
Red bat *Lasiurus blossevillii*	State: SSC	Wooded areas at lower elevations; typically roosts in snags and riparian trees with moderately dense canopies	Could occur; suitable foraging and roosting habitat present.
Yuma myotis bat *Lasiurus blossevillii*	State: SSC	Variety of habitats at low to mid elevations; roosts in buildings, trees, mines, caves, bridges, and rock crevices	Could occur; suitable foraging and roosting habitat present.

Table 9
Special-Status Wildlife Species with Potential to Occur in the Element IVc Mitigation Site Area

Species	Status	Habitat	Potential for Occurrence

[1] Legal Status Definitions:
Federal—U.S. Fish and Wildlife Service
E Endangered (legally protected)
T Threatened (legally protected)

State—California Department of Fish and Wildlife
E Endangered (legally protected)
T Threatened (legally protected)
FP Fully Protected (legally protected, no take allowed)
SSC California Species of Special Concern (no formal protection)

[2] Potential for Occurrence Definitions:
Unlikely to occur: Potentially suitable habitat present but species unlikely to be present on the project site because of current status of the species and very restricted distribution.
Could occur: Suitable habitat is available at the project site; however, few or no other indicators show that the species may be present.
Likely to occur: Habitat conditions, behavior of the species, known occurrences in the project vicinity, or other factors indicate a relatively high likelihood that the species would occur at the project site.
Known to occur: The species, or evidence of its presence, was observed at the project site during reconnaissance-level surveys or was reported by others.

Special-Status Fish Species

A total of ten special-status fish species occur or have the potential to occur in the San Joaquin River near the Mitigation Site. Of the 10 species, Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss)*, Central Valley spring-run Chinook salmon evolutionary significant unit (ESU) (*O. tshawytscha)*, Sacramento River winter-run Chinook salmon ESU (*O. tshawytscha)*, southern DPS of North American green sturgeon (*Acipenser medirostris)*, and Delta smelt (*Hypomesus transpacificus*) are Federally listed as threatened or endangered species. The USFWS delisted Sacramento splittail (*Pogonichthys macrolepidotus*) from its Federally threatened status on September 22, 2003; however, the listing status is currently being reviewed under court order. Longfin smelt (*Spirinchus thaleichthys*) is listed as threatened under the California Endangered Species Act. The National Marine Fisheries Service (NMFS) determined that listing is not warranted for Central Valley fall-/late fall-run Chinook salmon ESU (*O. tshawytscha)*; however, it is still designated as a species of concern because of concerns over specific risk factors. The two remaining species, San Joaquin roach (*Lavinia symmetricus* sp.) and hardhead (*Mylopharodon conocephalus*), are considered Species of Special Concern by the California Department of Fish and Wildlife. **Table 10** summarizes the regulatory listing status, habitat requirements, and the potential for occurrence for special-status fish species.

Table 10
Special-Status Fish Species Potentially Occurring in the San Joaquin River

Species	Status [1]		Habitat	Potential to Occur in the lower San Joaquin River
	USFWS/ NMFS	CDFW		
Central Valley steelhead *Oncorhynchus mykiss*	T	--	Requires cold, freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and Delta.	Occurs in the Sacramento and San Joaquin Rivers, tributaries, and Delta. Occurs seasonally in the San Joaquin River in the project vicinity.
Central Valley fall-/ late fall–run Chinook salmon *Oncorhynchus tshawytscha*	SC	SSC	Requires cold, freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and Delta.	Occurs in the Sacramento and San Joaquin Rivers, tributaries, and Delta. Occurs seasonally in the San Joaquin River in the project vicinity.
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	E	E	Requires cold, freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and Delta.	Occurs in the Sacramento River, tributaries, and Delta. Unlikely to occur in the San Joaquin River in the project vicinity; however, occasional adult and/or juvenile strays may be present.

Table 10
Special-Status Fish Species Potentially Occurring in the San Joaquin River

Species	Status [1] USFWS/ NMFS	Status [1] CDFW	Habitat	Potential to Occur in the lower San Joaquin River
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	T	T	Requires cold, freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and Delta.	Occurs in the Sacramento River, tributaries, and Delta. Unlikely to occur in the San Joaquin River in the project vicinity; however, occasional adult and/or juvenile strays may be present.
Green sturgeon *Acipenser medirostris*	T	--	Rears seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the Sacramento and San Joaquin Rivers, tributaries, and Delta. Has potential to occur in the San Joaquin River in the project vicinity.
Delta smelt *Hypomesus transpacificus*	T	T	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears seasonally inundated floodplains, tidal marsh, and Delta.	Occurs in tidally influenced segments of the Sacramento and San Joaquin Rivers, tributaries, and Delta. Has potential to occur in the San Joaquin River in the project vicinity.
Longfin smelt *Spirinchus thaleichthys*	–C/PT	T	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears seasonally inundated floodplains, tidal marsh, and Delta.	Occurs in tidally influenced segments of the Sacramento and San Joaquin Rivers, tributaries, and Delta downstream from the project area. Unlikely to occur in the San Joaquin River in the project vicinity.
Sacramento splittail *Pogonichthys macrolepidotus*	DT	SSC	Spawning and juvenile rearing from winter to early summer in shallow weedy areas inundated during seasonal flooding in the lower reaches and flood bypasses of the Sacramento River including the Yolo Bypass.	Occurs in the Sacramento and San Joaquin Rivers, tributaries, and Delta. Has potential to occur in the San Joaquin River in the project vicinity.
Hardhead *Mylopharodon conocephalus*	--	SSC	Spawning occurs in pools and side pools of rivers and creeks; juveniles rear in pools of rivers and creeks, and shallow to deeper water of lakes and reservoirs.	Occurs in the Sacramento and San Joaquin Rivers, tributaries, and Delta. Has potential to occur in the San Joaquin River in the project vicinity.
San Joaquin roach *Lavinia symmetricus* sp.	--	SSC	Spawning occurs in pools and side pools of small rivers and creeks; juveniles rear in pools of small rivers and creeks.	Occurs in tributaries to the Sacramento and San Joaquin Rivers. Not likely to occur in the San Joaquin River in the project vicinity.

Source: Moyle 2002; data compiled by AECOM in 2010 and revised by GEI Consultants, Inc. in 2016

The lower San Joaquin River serves as a migration corridor and/or provides other types of habitat (e.g., rearing, spawning) for Central Valley fall-/late fall-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, Sacramento River winter-run Chinook salmon ESU, Central Valley steelhead DPS, Delta smelt, Sacramento splittail, white sturgeon (*Acipenser transmontanus*), and North American green sturgeon.

The San Joaquin River adjacent to the Mitigation Site has been designated as critical habitat for Delta smelt, Central Valley steelhead, and the Southern DPS of North American green sturgeon.

JURISDICTIONAL DETERMINATION

Wetland delineations for the RD 17 Phase 3 Repair Project were conducted at multiple times to address project footprint changes and revisions to ensure the project design meets current USACE standards. The delineations were conduction on November 3, 2009, December 21, 2009, July 1, 2010, and again on February 13, 2014 (AECOM 2009a, 2009b, 2010, and 2014). The USACE issued Preliminary Jurisdictional Determinations for the project on November 10, 2009, April 9, 2010, October 21, 2010, and again on April 7, 2014.

No jurisdictional waters or wetlands were identified within the footprint for Element IVc. A delineation of the ordinary high water mark (OHWM) along the San Joaquin River was completed at Element IVc to address work on the waterside of the levee. The verified OHWM corresponds to approximately 4.7 feet in surface elevation. **Exhibit 8** shows the OHWM within Element IVc.

CULTURAL RESOURCES

There were no cultural resources identified within or adjacent to Element IVc.

REFERENCE SITE

A reference site serves as a template or model for restoration planning. It can be used for development of design characteristics and is used during the monitoring period to provide a yardstick for comparison and also to compare occurrences of variation due to natural events. It is anticipated that the Oxbow Preserve, owned and managed by the Center for Natural Lands Management, will be used as the reference site. The Oxbow Preserve is located on the right bank of the San Joaquin River at RM 55, just south of the Mitigation Site. The Oxbow Preserve was established in 2004 as mitigation for an adjacent development in Lathrop, CA. A baseline description of this site will be included in the Final MMP.

MITIGATION WORK PLAN

MITIGATION DESIGN

The design of the Mitigation Site is based on research, field visits, hydrologic investigations, consultation with the regulatory agencies and local authorities and consideration of the regional biological resources.

SPECIES ACCOUNTS AND DESIGN GUIDELINES

Detailed species accounts and relevant design guidelines for the Mitigation Site for riparian brush rabbit and VELB will be included in the Final MMP.

SCHEDULE AND SEQUENCE

A proposed schedule for the mitigation implementation is provided in **Table 11** below. Project implementation is dependent on receipt of all regulatory approvals and permits. Thus, it is subject to change.

Table 11
Anticipated Mitigation Implementation Schedule for Element IVc Mitigation Site

Date	Activity
Early Spring 2018	Plant Procurement
Early Summer 2018	Grading Contract Mobilization (part of larger levee construction contract) and Site Preparation
Summer 2018	Earthwork: topsoil salvage and storage, grading (with the exception of the levee breach), and topsoil placement, best management practices for erosion control.
Late Summer 2018	Grading Completion
Late Summer 2019	Setback Levee Accreditation[1]
Late Summer/Early Fall 2019	Breach Remnant Levee
Late Summer/Early Fall 2019	Site Soil Preparation and Amendment for Planting
Fall 2019	Planting: container plants, cuttings, seeding and mulching
Fall 2019	Irrigation System Installation
Fall 2019	Planting Completion: remove construction debris; site walk-through and acceptance with the contractor; complete and submit as-built drawings
December 2019 – December 2022	Maintenance Period: weed control, irrigation, caging and fencing maintenance, and re-planting as needed
January 2022	Maintenance Close-out: final as-built submittal
January 2020-December 2024	5-year Monitoring and Reporting Period
Winter/Early Spring 2025	Agency Sign-off and Transfer to Long-term Maintenance

Notes:
[1] The remnant levee cannot be breached until the new setback levee has been accredited. It is anticipated that the new levee will be accredited one year after construction.
Source: Data compiled by GEI Consultants, Inc. in 2016

CONSTRUCTION METHODS

The setback levee would be constructed as part of the larger Phase 3 Repair Project. After construction of the setback levee is completed, RD 17 must complete the levee accreditation process. Once this process is complete, the breach in the remnant levee, and planting would be completed. Earthwork within the Mitigation Site can be conducted concurrently with setback levee construction. Site preparation and planting within the setback area floodplain would be completed concurrently, or just after the levee breach for efficiency.

GRADING AND REMNANT LEVEE BREACH

Grading plans for the Mitigation Site are under development and will be provided in the Final MMP. As described above, grading and shaping of the Mitigation Site within the setback area can be completed concurrently with the setback levee construction and prior to breaching the remnant levee. The remnant levee breach shall be completed during the dry season to minimize the potential for erosion and sedimentation. Best management practices (BMPs) shall be implemented throughout the Mitigation Area during construction, especially downslope of potential construction-generated sediment source materials. Access routes for heavy equipment shall use the existing levee roads as much as possible or where necessary use the least potentially damaging route. Access points will be selected by the contractor in consultation with the restoration ecologist to ensure that sensitive riparian, woodland, and wetland resources are avoided.

DEMOLITION AND DEBRIS REMOVAL

During construction of the breach in the remnant levee, any associated debris will be removed from the Mitigation Site and disposed of properly. Any remaining gravel along the remnant levee crown road will be scraped and hauled off site. There are no other known items within the Mitigation Site boundaries that require demolition or removal. However, if additional items are identified during construction, they will be removed and properly disposed of offsite. Once planting is complete, any associated refuse will be removed by the contractor prior to site acceptance. During maintenance activities, any trash or debris will be removed and disposed of properly.

SOIL PREPARATION AND AMENDMENT

SOIL TESTING

Soil samples will be collected at the Mitigation Site prior to planting to assess soil fertility, texture, and structure. This soil testing will inform the need for soil amendment, preparation methods, and confirm that there are no site specific soil toxicity issues that may result in high plant mortality. To detect potential site variability, soil sample collection will be representative of all soil types and landforms within the Mitigation Site. A minimum of three samples will be collected from each unique location. Soil samples for fertility analysis will be collected using a clean soil probe. At the same locations, soil texture and structure will be assessed in the field using a larger soil pit dug to approximately 18–24 inches in depth. Within the Mitigation Site, it is anticipated that samples will be taken from the basin within the setback area, and from the slope and crown of the remnant levee. Approximately 9–12 samples will be collected and submitted to a qualified soil testing lab for analysis.

Based on fertility testing and field assessment results, soil amendment recommendations will be developed and included in the Final MMP. Recommendations to correct for pH or fertility issues, or to improve permeability will be included, if necessary.

SOIL STORAGE

Where grading is planned within the setback area at the Mitigation Site, the top 6 inches of soil and organic materials will be stripped and salvaged. Areas with heavy infestations of invasive species, as determined by a qualified restoration ecologist, will be avoided. In areas where fill is needed within the Mitigation Site, the interim grade will be set to 6 inches below finish grade. Salvaged topsoil will be incorporated to attain the finish grade. Topsoil will be stockpiled, minimizing handling and compaction to the greatest extent feasible. Topsoil will be stored dry; water application, if necessary for dust control, will be minimized to the extent feasible. If topsoil storage is necessary, it will be stored in narrow rows for up to three months. Storage piles should be protected using appropriate stormwater BMPs to avoid adverse impacts to water quality.

Soil Preparation

Detailed soil preparation methods will be provided in the Final MMP once soil analysis has been conducted at the Mitigation Site.

PLANTING AND SEEDING

Preliminary plant palettes for the Mitigation Site are provided below (**Tables 12a, 12b, 13a, 13b, and 13c**). Seeding application rates, container plant sizes and planting ratios will be provided in the Final MMP. The Final MMP will include detailed guidelines on: plant procurement, including maintaining genetic integrity and appropriate sources for plant materials; seeding and planting techniques, including harvesting and planting willow pole cuttings; and plant protection. The Final MMP will also include a detailed planting plan and irrigation plan. The irrigation plan will identify the water source and point of connection, and provide the irrigation layout for the Mitigation Site.

Plant Palettes

Plant palettes for seeding and container planting have been carefully chosen based on the current knowledge of Mitigation Site conditions, including soils, hydrologic regime, precipitation, proximity to the water table and habitat requirements for the riparian brush rabbit and VELB. As site design evolves, and additional site information is available (including the fertility soil testing results), the plant palettes may be modified for the Final MMP. Seed mixes for the Mitigation Site are presented in **Tables 12a and 12b**, and container plant palettes are presented in **Tables 13a, 13b, and 13c**.

OTHER HABITAT FEATURES

PROTECTIVE FENCING

Feral cats are common predators of the riparian brush rabbit. The close proximity of residential neighborhoods to riparian scrub habitat creates a source of potential predators. To reduce potential for feral or residential pet cats to enter the Mitigation Site, an exclusion fence will be installed on the western side of the new setback levee. The fencing location, design, and details will be included in the Final MMP. It is anticipated that the fence will be 6-foot high chain-link with a 2-foot 'floppy' overhang and steel posts. This type of fence has been proven to exclude feral cats effectively during experimental studies (Moseby and Read 2006).

RESOURCE PROTECTION MEASURES

Implementation at the Mitigation Site will follow the same resource protection measures identified in and required by regulatory authorizations for the Phase 3 Repair Project. All permit conditions and California Environmental Quality Act and National Environmental Policy Act mitigation measures related to pre-construction surveys, construction monitoring for protection of biological resources, cultural resources, and water quality will be followed.

IMPLEMENTATION BUDGET AND FUNDING

The Final MMP will include an itemized budget for mitigation implementation. The budget will include estimated costs for the following elements:

- Land acquisition
- Planning and engineering
- Legal fees
- Mobilization
- Construction
- Planting and irrigation
- Monitoring and reporting

MAINTENANCE AND MANAGEMENT

Maintenance during the establishment period of a mitigation site is a critical component for success. Conducting vegetation management at targeted times will reduce planting mortality, and ultimately reduce the cost of attaining required performance standards. The ultimate goal of the maintenance and vegetation management program is to establish a mitigation site that will be self-sustaining in perpetuity. By providing enough initial support to the mitigation plantings, the Mitigation Site can become a vigorous ecosystem that thrives without supplemental intervention.

A detailed maintenance and vegetation management plan for the Mitigation Site will be developed and provided in the Final MMP. RD 17 or RD 17's contractor will be responsible for implementing the maintenance program during the establishment period.

VEGETATION MANAGEMENT

Using an integrated pest management approach, vegetation management on the Mitigation Site will draw from a full spectrum of tools including the use of physical/mechanical, ecological, and/or chemical techniques to support establishment of mitigation plantings and reduction or suppression of non-native and/or invasive species. During Mitigation Site evaluation, a full list of current and potential invasive species will be recorded. The timing and frequency of the maintenance efforts will be based on the biology of the invasive species that require control. The vegetation management plan will account for all requirements in the VELB Guidelines (USFWS 1999), and protection of nesting birds and special-status species.

ADAPTIVE MANAGEMENT AND CONTINGENCY MEASURES

Using an adaptive approach is the cornerstone of an adequate management and monitoring program. Mitigation Site design is based on the best available science and a comprehensive ecological evaluation. However, over time, conditions can change, new information may become available, unanticipated factors may influence site conditions, a stochastic environmental event (e.g., fire) may occur, or the site may be vandalized. If this occurs, it is likely the Mitigation Site will fail to meet performance standards (as defined in the "Performance Standards, Monitoring and Reporting" section of this MMP). If this occurs, it would trigger evaluation and analysis of the problem, and assessment of the Mitigation Site design and/or management plan to develop corrective measures. If large-scale changes occur on the Mitigation Site that require unanticipated actions (e.g., site grading, large scale replanting, managing large-scale pest infestations, etc.), RD 17 will develop a recommended course of action and consult with USFWS and the other regulatory agencies prior to implementing those measures.

If performance standards are not met due to routine plant mortality or small-scale weed or pest infestations, RD 17 or its representative will analyze the cause(s) of failure, and implement remedial actions to correct the performance deficiency. RD 17 will summarize the analysis and the specific remedial actions taken to correct the identified deficiency in the annual monitoring report submitted to USFWS and the other regulatory agencies. If the Mitigation Site does not meet a final performance standard, RD 17's maintenance and monitoring obligations will continue until USFWS confirms in writing that RD 17 has met the required conditions.

PERFORMANCE STANDARDS, MONITORING, AND REPORTING

After the mitigation implementation effort is completed, the Mitigation Site will be monitored as defined below, or until the final performance standards are met.

ECOLOGICAL PERFORMANCE STANDARDS

The Final MMP will establish ecological performance standards for the Mitigation Site once the site design has been finalized. Performance standards will be established for canopy cover and plant survival. The final performance standards must be reached without remedial intervention (e.g., irrigation, greater than 20% replacement planting) for a minimum of 2 sequential years. Monitoring must continue until 2 sequential years of independence have been achieved.

MONITORING METHODS AND SCHEDULE

The Final MMP will provide detailed monitoring methods and a monitoring schedule for the Mitigation Site. It is anticipated that the monitoring period for the entire setback area will be a minimum of 5 years. Both quantitative and qualitative monitoring will be conducted at the Mitigation Site.

Qualitative monitoring will be conducted during each quantitative monitoring visit. Qualitative monitoring will provide an opportunity to document general plant health, overall plant community composition, hydrologic conditions, site damage, infestation of weeds, signs of excessive herbivory, erosion problems, and signs of human disturbance and vandalism. These criteria will be assessed and noted for use in adaptive management of the Mitigation Site. A list of all wildlife species observed will be compiled for the Mitigation Site during each monitoring visit.

Annual photo-documentation from fixed photo points will also be conducted. Selection of the photo points will provide appropriate views and orientation for a comprehensive assessment of the progress of the Mitigation Site.

It is anticipated that canopy cover within the Mitigation Site will be estimated using the line transect method. Permanent transects will be established using aerial photography. Approximately 10 transects, 150 feet in length, will be sampled. The height and width of the trees and shrubs along each transect will be recorded to provide supplemental information on site performance and species health.

Monitoring for the VELB elderberry seedlings and associate plantings will follow the VELB Conservation Guidelines (USFWS 1999). It is understood that the VELB Guidelines are currently under revision. If the revised guidelines become available during the monitoring period, monitoring methods for the remainder of the monitoring period will be adapted in accordance with these revisions to the extent feasible. However, the length of the monitoring period would not be extended.

MONITORING REPORTS

CONSTRUCTION COMPLETION REPORT AND AS-BUILTS

Within 60 days of completing mitigation implementation of the Mitigation Site, RD 17 will submit to USFWS and the other regulatory agencies a memo documenting major mitigation implementation milestone completion dates and as-built plans. If there were any substantial deviations from the original designs, a clear description of the modifications that were made and the rationale behind the changes will be provided.

If mitigation habitats are created in excess of that needed to mitigate for the Phase 3 Repair Project impacts, the acreage of these habitats will be recorded with the as-built drawings. Extra acreage will provide a contingency in the event of Phase 3 Repair Project changes that require additional mitigation acreage, or if portions of the mitigation components do not fulfill the performance standards.

ANNUAL MONITORING REPORTS

During the establishment and monitoring period, RD 17 will prepare an annual mitigation monitoring report that will be submitted to USFWS by March 30 following the monitoring year until the final performance standards have been met. The report will assess the attainment of or progress toward meeting the performance standards for the Mitigation Site.

The report will include the following relevant information:

- a list of individuals who conducted monitoring activities and prepared the monitoring report for that year, including titles and affiliations;
- maps of the Mitigation Site including: a vicinity map and a map that depicts established habitat types, photo-point locations, and monitoring transect locations;
- a summary and analysis of the monitoring data collected, including a qualitative assessment of site characteristics, functions, and services;
- a comparison of the monitoring results with performance standards;
- results of habitat monitoring for VELB in accordance with the VELB Guidelines (USFWS 1999);
- a list of target native plant and invasive weed species growing within the Mitigation Site;
- a description of actions for which regulatory agency notification or approval was not needed, but that were carried out during the year;
- discussion of and rationale for any substantial modifications made to monitoring methods;
- a description of actions for additional or modified adaptive management practices, as needed, for the next calendar year, that includes timing, and methods necessary to meet the performance standards within the establishment period; and
- a photo appendix documenting the conditions of the Mitigation Site; the photo appendix will include the location, date, and direction photo was taken.

Copies of all field data sheets will be available for regulatory agency review upon request.

COMPLETION OF MITIGATION RESPONSIBILITIES

RD 17 will notify USFWS and the other regulatory agencies through the annual monitoring report when the performance standards are met and the establishment period specified in the monitoring program is complete. It is recognized that USFWS and the other regulatory agencies may require visits to the Mitigation Site. With prior notification, USFWS may visit the Mitigation Site at any time to verify that project mitigation requirements have been completed. After verification, USFWS will provide RD 17 with written confirmation that they have met the required mitigation obligations and responsibilities.

LONG-TERM MANAGEMENT AND FUNDING

RD 17 is in the process of negotiating purchase of the Mitigation Site property. It is anticipated that RD 17 will own and manage the property in perpetuity. It is anticipated that the site will be protected as habitat in perpetuity using deed restrictions, a conservation easement, or similar preservation mechanism acceptable to USFWS. The Final MMP will identify the specific mechanism with which the site will be protected. A copy of the long-term preservation mechanism will be provided to USFWS and the other regulatory agencies.

LONG-TERM MANAGEMENT PLAN

A Long-term Management Plan (LTMP) will be developed for the Mitigation Site and submitted to USFWS and the other regulatory agencies prior to the start of construction. The LTMP will identify long-term management needs and other activities necessary to maintain the functions and values of the Mitigation Site. The LTMP will cover: general inspections and monitoring; signage; site maintenance including: fencing maintenance, vegetation management, managing trespass, trash removal, fire hazard reduction, and erosion control; and reporting. The LTMP will also address adaptive management measures that may be needed due to future changes as described under the "Adaptive Management and Contingency Measures" section above. Annual costs required to implement the long-term management and maintenance will be estimated and documented in the LTMP. The LTMP will take effect once the Mitigation Site has met required performance standards and mitigation responsibilities have been deemed as completed in accordance with USFWS and the other regulatory agencies.

FUNDING AND FINANCIAL ASSURANCES

RD 17 will be responsible for funding and implementing mitigation implementation and long-term management and monitoring. RD 17 will work with USFWS and the other regulatory agencies to identify an acceptable mechanism to fund long-term management and maintenance. The Final MMP will identify the funding mechanisms that will be put in place to provide adequate funds to manage and maintain the Mitigation Site in perpetuity.

APPENDIX B

MBK Engineers: Site Specific Inundation Frequency and Duration

RD 17 Levee Setback IV-c
Evaluation of Frequency of Project Area Inundation

Mike Archer, MBK Engineers
2/23/16

An evaluation of the frequency of flooding of the RD 17 IV-c levee setback offset area was made in August 2015 for the original project plan with an invert elevation for the breach connecting the San Joaquin River to the offset area of 14 feet (NAVD88). An additional request has been made for the frequency of inundation with breach inverts of 10 feet (NAVD88) and 8 feet (NAVD88).

Based on the hydraulic model analysis, the estimated flow at the location of the San Joaquin River near Vernalis USGS stream gage (Vernalis gage), about 17.5 miles upstream of the project area, at which water would enter the setback area through the remnant levee breach for the three breach invert elevations is shown in Table 1. An estimate of the return interval of the Vernalis flow, from a HEC-SSP Bulletin 17b analysis of the Vernalis gage record, is included in Table 1. Also included for information is the corresponding computed flow in the San Joaquin River at the project location.

Table 1. Estimated Flows Above Which the Project Area Would Flood

Breach Invert Elevation (feet, NAVD88)	Flow in San Joaquin River near Vernalis above which project breach flow occurs (cubic feet per second)	Estimated Return Interval	Flow in San Joaquin River at breach location (cubic feet per second)
8	9,500	2 year	4,200
10	13,200	3 to 4 year	5,700
14	24,000	6 year	8,800

To evaluate how often and how long the project area would expect to be inundated, a review was made of the historical San Vernalis gage daily flow records since the completion of New Melones Dam in 1979 (this represents a period where the San Joaquin River basin operating regime has been relatively unchanged). The evaluation used the mean daily flows for the period 10/1/1978 through 9/30/2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. Table 2 summarized the estimated number and percent of days in the evaluation study period in which the Project area would flood.

Table 2. Estimated Total Duration of Project Area Flooding for Evaluation Period of Record

Breach Invert Elevation (feet, NAVD88)	Flow in San Joaquin River near Vernalis above which project breach flow occurs (cubic feet per second)	Number of days flow equaled or exceeded since 10/1/78	Percent of days flow equaled or exceeded since 10/1/78
8	9,500	1,619	12.0%
10	13,200	1,126	8.3%
14	24,000	423	3.1%

Table 3 summarizes the estimated number of days in each water year that the Project area would flood for each of the three breach invert elevations, along with estimates of average and maximum depths of flooding in each water year. The depths were computed relative to the breach invert elevation. Estimating the depth in the offset area was done with a two-step process:

1. Development of a regression correlation between the mean daily flow gage record at Vernalis and the mean daily stage at the DWR San Joaquin River below Old River near Lathrop gage. This relationship was used to estimate a mean daily stage at the Lathrop gage based on mean daily flow at Vernalis. This was necessary because the Lathrop gage record starts in 2002.

2. Development of regression correlation between the stage at the Lathrop gage and the stage at the remnant levee breach. This relationship was derived from hydraulic model computed data. It was used to translate the estimated stage at the Lathrop gage from step 1 to the remnant levee breach location.

A chronological plot of the Vernalis mean daily flow for the evaluation period of record is provided in Figures 1 and 2. Also indicated on these figures are the Project area flooding thresholds for each of the breach invert elevations.

Table 3. Estimated Annual Duration of Project Area Flooding for Evaluation Period of Record

Response to NMFS's July 2015 Request for Additional Information

October 7, 2016

RESPONSE TO NATIONAL MARINE FISHERIES SERVICE'S JULY 2015 REQUEST FOR ADDITIONAL INFORMATION ON BIOLOGICAL ASSESSMENT

This is in response to the National Marine Fisheries Service (NMFS) July 7, 2015, letter requesting additional information to support the request for initiation of informal consultation with the U.S. Army Corps of Engineers (USACE) on the Reclamation District 17 (RD 17) Phase 3 Levee Seepage Repair Project (Project) in San Joaquin County, California. To respond to the request, we have bracketed the NMFS July 7, 2015, letter and have organized our responses accordingly.

Response to Comment 1a

The following information has been incorporated into the "Setback Levee with Seepage Berm and Underlying Cutoff Wall" subsection of the "Description of the Proposed Phase 3 Repair Project" section on pages 22-25 of the BA.

Of direct benefit to fish resources is the inclusion of project Element IVc, which includes construction of a 1,240-foot-long setback levee with cutoff wall and seepage berm, on a major oxbow of the San Joaquin River (see Table 2 of the biological assessment [BA]). A Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project (Conceptual MMP) (RD 17 2016) has been prepared to describe the expansion and restoration of riparian habitat in Element IVc; this document has been added as an attachment to the BA (Appendix E).

Setback Description. The cutoff wall would involve degrading the top one-third to one-half of the existing levee crown where it would intersect the new setback levee and would begin with a 1:1 cut at the waterside crown. Approximately 0.64 acres (110 linear feet) of riprap would be installed on the waterside of the existing levee (above the high tide line) where it would intersect the setback levee. After the setback levee is completed, 400 linear feet of the existing levee above the high tide line on the downstream side of the oxbow would be degraded, reconnecting approximately 8 acres of floodplain to the river. That floodplain area would be graded to allow complete drainage of the floodplain to the river through the downstream opening in the remnant levee, as river flows recede.

i. The elevations of the newly "exposed" floodplains in the area of the setback levee. The Conceptual MMP evaluates three breach invert elevations (8 feet [NAVD88], 10 feet [NAVD88] and 14 feet [NAVD88]) for the proposed levee breach on the downstream end of the oxbow. Hydraulic modeling, based on San Joaquin River flows as reported at the Vernalis USGS stream gage (Vernalis gage), about 17.5 miles upstream of the project area, was used to estimate the flow in the San Joaquin River at which water would enter the setback area through the remnant levee breach for these three breach invert elevations. The results are shown in Table 1.

Table 1
Estimated Flows for Inundation of the Element IVc Mitigation Site

Breach Invert Elevation (feet, NAVD88)	Flow in San Joaquin River near Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Estimated Return Interval	Flow in San Joaquin River at Breach Location (cfs)
8	9,500	2 year	4,200
10	13,200	3 to 4 year	5,700
14	24,000	6 year	8,800

Note: cfs = cubic feet per second Source: MBK Engineers 2016

ii. The expected frequency of inundation during high water events.

and

iii. The expected durations of inundation under different high water stages.

To evaluate how often and how long the setback levee area would be expected to inundate, a review was made of the historical Vernalis gage daily flow records since the completion of New Melones Dam in 1979 (this represents a period where the San Joaquin River basin operating regime has been relatively unchanged). The evaluation used the mean daily flows for the period October 1, 1978 through September 30, 2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. Table 2 summarizes the estimated number and percent of days in the evaluation study period in which the levee setback area would flood based on each of the three invert elevations. Based on the historical data, the periods during which water would flow into the project breach at the three invert elevations are displayed in the figures below.

The appropriate breach elevation is under consideration and will be defined in the Final MMP. It is anticipated that the breach elevation would be set at approximately 9 or 10 feet (NAVD88). Approximately 1-2 acres of the floodplain would be set to an elevation of 14 feet (NAVD 88) or below and would inundate approximately every 6 years.

Table 2
Estimated Total Duration of Mitigation Site Flooding for Evaluation Period of Record

Breach Invert Elevation (feet, NAVD88)	San Joaquin River Flow at Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Number of Days Flow Equaled or Exceeded Since 10/1/1978	Percent of Days Flow Equaled or Exceeded Since 10/1/1978
8	9,500	1,619	12%
10	13,200	1,126	8.3%
14	24,000	423	3.1%

Note: cfs = cubic feet per second
Source: MBK Engineers 2016

i. Potential for stranding in any depressions or perched areas within the levee setback area. The floodplain would be graded to drain to a central swale, approximately 2-feet deep. As flood flows recede, the swale would drain completely through the breach in the remnant levee. This would minimize the possibility of fish stranding. A major benefit to fish resources would be the reactivation of floodplain rearing habitat for juvenile salmonids, in particular, and other native fishes as well. The seasonal nature of inundation, along with complete drainage, precludes establishment in the floodplain of predatory, non-native fishes.

Response to Comment 1b

Information about the exclusion of setbacks has been provided in the BA, with information specifically incorporated into the “Setback Levee Considerations” subsection of the “Description of the Proposed Action” Section on page 22 of the BA. The complete hydraulic analyses that evaluated the setback levee alternatives are included as a new appendix to the BA (Appendix F).

Plan formulation, including the rationale for not incorporating additional setback levees into the proposed action, is discussed in greater detail in Section 2.1.4 of the Draft Environmental Impact Statement/Environmental Impact Report (DEIS/EIR; USACE and RD 17 2011). As discussed in the DEIS/DEIR, setback levees were considered but eliminated from further consideration in several project reaches for the reasons listed below.

- Construction of a setback levee along certain stretches of the river were hydraulically constrained and would have greatly increased the project scope to the point of being cost prohibitive (Elements VIa.4 and VIb).
- Because of the proximity to the bifurcation at Old River, the change in hydraulic conditions that would result from constructing a setback levee at Elements Va and VIa.1 would increase flows down the San Joaquin River during flood events, which could lead to increased flooding downstream (Elements Va and VIa.1).
- Construction of a setback levee relative to other levee improvement alternatives and/or land acquisition to accommodate the construction of a setback levee was cost prohibitive (Elements Ie, IIab, IIIb, IVa, VIcde, and VIIb).
- Existing landside development constrained the option of constructing a setback levee (Elements Ia, IIab, VIIe and VIIg).

Response to Comment 1c

As stated in the “San Joaquin Multi-Species Conservation Plan” subsection of the “Species Considered” section on page 13 of the BA, “…because the [San Joaquin Multi-Species Conservation Plan (SJMSCP)] does not cover special-status fish, the conversion of riparian brush rabbit habitat, or impacts on other species on the waterside of the levee, RD 17 and USACE would not rely on the SJMSCP to assess and offset Phase 3 Repair Project effects on federally listed and State-listed species. Rather, through this BA and the associated Section 7 consultations with USFWS and NMFS, RD 17 and USACE would seek take authorization for Phase 3 Repair Project activities.”

Mitigation relative to project construction is directed solely towards terrestrial habitats and species, and not towards aquatic species, including listed anadromous species, because there will be no significant effects to those aquatic species or their habitat (including essential fish habitat [EFH]) resulting from project construction or implementation. All waterside activities will be conducted out of the channel, and best management practices (BMPs) will ensure the stability of sediments on the levee and floodplain. No mitigation is necessary for aquatic species or habitats.

Response to Comment 1d

All waterside work activities are anticipated to be completed inside the work window (i.e., between July 1 and November 1). No work will be conducted within the stream channel and BMPs will ensure the stability of sediments during construction activities that occur on the levee and floodplain. As stated under the “Proposed Schedule and Sequence of Project Construction” subsection under the “Description of the Proposed Phase 3 Repair Project” section on pages 25-28 of the BA,” The general levee construction window is seasonal (July 1–November 1), avoiding the period when high-water levels have the potential to occur within the San Joaquin River system. However, depending on hydrologic conditions, and subject to compliance with special-status species work windows, the CVFPB may grant a variance allowing work to occur outside the July 1 to November 1 work window. The CVFPB may stipulate that RD 17 has to comply with additional conditions and commitments as a component of any work window variance.”

Response to Comment 2

The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project. Areas downstream of the Phase 3 Repair Project area might also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions. The extent of this potential effect is difficult to quantify, however, for Element IVc, construction of a setback levee and breaching a small downstream portion of the existing levee would be expected to create a backwater effect and would not result in a substantial widening of the flood plain. An analysis also was conducted to evaluate the hydraulic effects of the setback levee at Element IVc. This hydraulic analysis showed that the proposed action would essentially have no effect on the maximum water surface elevation, with a computed maximum increase in the water surface elevation of 0.0007 feet, and maximum flow rate changes would be negligible during extreme events (100-year flood recurrence interval) (see Appendix F to the revised final BA).

Since far afield project-related hydrologic effects are not likely to occur, the action area is concluded to be designated as the immediate vicinity of the actual project boundaries, and the BA has been updated accordingly to reflect this as the action area.

Response to Comment 3a

Five-year status reviews for the listed Central Valley Chinook salmon, Central Valley steelhead, and southern distinct population segment (DPS) of green sturgeon have been reviewed and pertinent information from those documents has been included, and cited, in the BA. Species accounts for those listed species have been updated in the BA.

Response to Comment 3b

A recovery plan for the evolutionarily significant units (ESUs) of Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon and the DPS of Central Valley steelhead was finalized by NMFS in July 2014 (NMFS 2014a). The plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. The recovery plan has been reviewed and pertinent information from that document has been included, and cited, in this BA. A recovery plan has not been developed for green sturgeon, however the Federal Recovery Outline for the Southern DPS is available (NMFS 2010). Species accounts for those listed species have been updated in the BA with information from the recovery plans.

Response to Comment 3c

As discussed in the "San Joaquin River" subsection of the "Environmental Baseline" section on pages 36-37 of the BA, one of the goals of the San Joaquin River Restoration Program (SJRRP) is "to restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish" (Reclamation and DWR 2011). The SJRRP Settlement stipulates reintroduction of spring-run and fall-run Chinook salmon, with a priority given to restoring self-sustaining populations of wild spring-run Chinook salmon. Juvenile spring-run Chinook salmon were released into the system in 2014, 2015, and 2016. Tracking these fish and their return to the system has proven challenging. Additional efforts are underway by the SJRRP partners to identify and implement alternative technologies to improve tracking (NMFS 2014d).

Surveys indicate that populations of remnant, non-sustaining spring-run Chinook salmon may be found in Cottonwood, Battle, Antelope, and Big Chico Creeks (DWR 1997); more sizable, consistent runs of naturally produced fish are found only in Mill, Deer, and Butte creeks (Williams et al. 2014). All these creeks are tributaries in the Sacramento River basin. The Feather River Fish Hatchery sustains the spring-run population on the Feather River, but the genetic integrity of that run is questionable (DWR 1997). Although all of these populations are found in the Sacramento river basin, the ESU boundary of Central Valley spring-run Chinook salmon includes populations spawning in the Sacramento River and San Joaquin River basins, as reflected in the current 5-Year status review (Williams et al. 2014; NMFS 2011). The status of Central Valley spring-run Chinook salmon ESU has likely not improved since 2005 status review (Williams et al. 2014). Improvement of spring-run Chinook salmon ESU is dependent upon improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects are also of primary importance in improving the status of this ESU (NMFS 2014a). Current and future efforts to restore production in the San Joaquin River are either being planned or are just beginning, and no results as to their current efficacy are available.

Like winter-run Chinook salmon, adult spring-run Chinook salmon other than occasional strays generally have not been documented in the San Joaquin River basin, and therefore, unlikely to occur in the action area at this time. The same is true for juvenile spring-run Chinook salmon.

Response to Comment 3d

Amendment 18 to the Pacific Coast Salmon Fishery Management Plan revises the description and identification of EFH for Pacific salmon (in this case, Chinook salmon), designates habitat areas of particular concern (HAPC), modifies the current information on fishing activities and potential measures to minimize their effects on EFH, and updates the list of fishing and non-fishing related activities that may adversely affect EFH and potential conservation and enhancement measures to minimize those effects (NMFS 2014c). EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia from high flows during floods as salmon migrate along the mainstem in this area.

This information does not essentially change the analysis of potential effects to EFH relative to the Phase 3 Repair Project, included in response to comment 7 (see below). Construction of Element IVc would improve EFH by providing the type of refuge habitat for juvenile Chinook salmon during high flows as described in Amendment 18 for the lower San Joaquin River tributaries (NMFS 2014b).

Response to Comment 4a

Relative to the construction-related effects to fish in the action area, fish population levels and survival have been compared to various levels of turbidity and siltation in waterways. The following information is incorporated into the "Temporary Construction-Related Effects" subsection, which is in the "Direct and Indirect Effects on Species in the Action Area" Section under "Federally Listed Fish Species" on page 55 of the BA. Prolonged exposure to high levels of suspended sediment could create a loss of visual capability in fish, leading to a reduction in feeding and growth rates, and to a thickening of the gill epithelia, which may cause the loss of respiratory function; clogging and abrasion of gill filaments; and increases in stress levels, reducing the tolerance of fish to disease and toxicants (Waters 1995). Also, high levels of suspended sediments could cause the movement and redistribution of fish populations or other aquatic organisms, and could affect physical habitat (Waters 1995). Sediment loading could interfere with photosynthesis of aquatic flora and displace aquatic fauna. Many fish and other aquatic species are sight feeders, and turbid waters reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, could become disoriented and leave areas where their main food sources were located, ultimately reducing their growth rates. Increased turbidity and sedimentation cause fish to avoid an area, thus reducing available habitat. Fish will not occupy areas unsuitable for survival unless they have no other option. Therefore, construction-related erosion could result in elevated river turbidity in critical species-specific and life stage-specific habitats, potentially precluding a species from occupying that habitat.

Through the implementation of water quality BMPs, including a storm water pollution prevention plan, the proposed conservation measures (see the "Avoidance and Minimization Measures" section in the BA) would avoid direct and indirect take of fish during construction. The impact would not be expected to have an effect on the overall existence and survival of these species.

Response to Comment 4b

The following information is incorporated into the "Temporary Construction-Related Effects" subsection, which is in the "Direct and Indirect Effects on Species in the Action Area" section under "Federally Listed Fish Species" on page 55 of the BA. The potential would exist for contaminants such as bentonite slurry, fuels, oils, and other products used in construction to be introduced into the waterway directly or through surface runoff. Contaminants might be toxic to fish, or might alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival.

Through the implementation of water quality BMPs, including a storm water pollution prevention plan, and BMPs for slurry management and a slurry spill contingency plan, the proposed conservation measures (see the "Avoidance and Minimization Measures" section in the BA) would avoid direct and indirect take of fish during construction. The impact would not be expected to have an effect on the overall continued existence and survival of these species.

Response to Comment 4c

The following information is incorporated into the "Benefits of Project Actions to Rearing Salmonids" subsection, which is in the "Direct and Indirect Effects on Species in the Action Area" section under "Federally Listed Fish Species" on pages 56-58 of the BA.

i. Changes in growth rate for fish rearing on the floodplain. Sommer et al. (2001) provided evidence that the Yolo Bypass, the primary floodplain of the lower Sacramento River, provides better rearing and migration habitat for juvenile Chinook salmon than adjacent river channels. During 1998 and 1999, salmon increased in size substantially faster in the seasonally inundated agricultural floodplain than in the river, suggesting better growth rates. Similarly, coded-wire-tagged juveniles released in the floodplain were significantly larger at recapture and had higher apparent growth rates than those concurrently released in the river.

   Improved growth rates in the floodplain were in part a result of significantly higher prey consumption, reflecting greater availability of drift invertebrates. Bioenergetic modeling suggested that feeding success was greater in the floodplain than in the river, despite increased metabolic costs of rearing in the significantly warmer floodplain. Growth, survival, feeding success, and prey availability were higher in 1998 than in 1999, a year in which flow was more moderate, indicating that hydrology affects the quality of floodplain rearing habitat. These findings support the predictions of the flood pulse concept and provide new insight into the importance of the floodplain for salmon.

   Work by Jeffres et al. (2008) and Sommer et al. (2001) indicate that off-channel floodplain habitats provide significantly improved rearing habitat, supporting higher growth rates, than the intertidal river channel. However, their work shows that providing habitat complexity for juvenile salmon in floodplains is of utmost importance, so fish can find optimal places for rearing under varying flow conditions. It is well documented that survivorship to adulthood is increased when young salmonids leave freshwater at a larger size (Unwin 1997; Galat and Zweimuller 2001). Studies by Jeffres et al. (2008), Sommer et al. (2001), and others show that floodplain habitat restoration in Central California has major benefits to Chinook salmon populations, especially relative to growth and production.

   These studies indicate bioenergetic improvement to salmonids rearing in a flooded terrestrial floodplain because of the abundance of zooplankton (primary production), rather than having to rely on less dense prey items in the riverine channels, such as larval fish and benthic macroinvertebrates, and expending more energy for their capture. Therefore, construction of Element IVc would likely result in bioenergetic improvement for all listed species.

ii. Risk of predation from predators on the floodplain. The full 8 acres of floodplain would be graded to allow flood flows to drain out through the downstream breach in the remnant levee. This would minimize the possibility of fish stranding. The seasonal nature of inundation, along with complete drainage, precludes establishment in the floodplain of predatory, non-native fishes.

iii. Risk of stranding during the high water recession phase. The full 8 acres of floodplain would be graded to allow flood flows to drain out through the downstream breach in the remnant levee. This would minimize the possibility of fish stranding. The major benefit to fish resources would be the creation of approximately 8 acre of floodplain rearing habitat for juvenile salmonids, in particular, and other native fishes, in general.

iv. How frequently the floodplain becomes available to emigrating fish and for how long at different water elevations. Please see our response to Comment 1a.

v. Using the above information, an integration and synthesis of the variable effects of the setback levee should be performed which determines the net benefits to listed fish and fall-run Chinook salmon. Floodplain and other off-channel habitat restoration is important for improving production of juvenile salmonids in California's Central Valley. Juvenile salmonid emigration is generally passive during high flow events (Healey 1980; Kjelson et al. 1981); they are essentially entrained in the water column until they encounter slower water velocities where active swimming becomes possible. The San Joaquin River, like most rivers in the Central Valley, is incised and lacks channel complexity.

With the exception of the Yolo Bypass for the Sacramento River (Sommer et al. 2001), juvenile salmonids are frequently displaced downstream to the intertidal delta where growth is diminished during high flows in systems that lack access to floodplains. However, protected floodplain habitat, as would be created at Element IVc, would provide protection for juvenile salmonids being swept downstream during high flow events.

High San Joaquin River outflows generally occur during winter and early spring months. Juvenile fall/late fall-run Chinook salmon and Steelhead outmigration occurs at least partially during this period, while Central Valley spring-run Chinook salmon and green sturgeon outmigration occurs later.

- Central Valley fall-/late fall-run Chinook salmon outmigration may begin as early as November and extends through June,
- Central Valley spring-run Chinook salmon juvenile outmigration generally occurs from April through June,
- Central Valley Steelhead juvenile outmigration generally occurs from December through March in the San Joaquin River, and continues through June in the Delta.
- North American Green Sturgeon outmigration of older juveniles generally occurs from June through September,

The presence of the protected floodplain would likely benefit juvenile fall/late fall-run Chinook salmon and steelhead during high flow events. The configuration of the floodplain being protected during high flows facilitates protection of juvenile salmonids as they are directed into the floodplain through backflow currents and are not displaced any further downstream. Additional benefits to out-migrating juvenile spring-run Chinook salmon and green sturgeon would likely be negligible since outmigration occurs after high flow events. However, all listed species would benefit from increased floodplain.

Floodplain and other off-channel habitat restoration is important for improving production of juvenile salmonids in California's Central Valley. Juvenile salmonid emigration is generally passive during high flow events (Healey 1980; Kjelson et al. 1981); they are essentially entrained in the water column until they encounter slower water velocities where active swimming becomes possible. The San Joaquin River, like most rivers in the Central Valley, is incised and lacks channel complexity.

> With the exception of the Yolo Bypass for the Sacramento River (Sommer et al. 2001), juvenile salmonids are frequently displaced downstream to the intertidal delta where growth is diminished during high flows in systems that lack access to floodplains.

Response to Comment 4d

Levee improvements by themselves would not result in growth. Future growth is subject to existing and future specific plans and associated analysis, documentation, regulatory permits, and decisions that will incorporate all permitting requirements. The "Cumulative Effects" section on pages 59-62 of the BA presents a summary of indirect effects related to planned growth.

Response to Comment 4e

Development projects (i.e., residential, commercial, industrial), infrastructure projects, and flood facilities improvement projects include or would include grading and other earthmoving activities that could result in temporary and short-term localized soil erosion that could affect hydrology. However, these site-specific impacts are not expected to combine with the effects of other activities, because compliance with the National Pollutant Discharge Elimination System regulations, including construction site BMPs, would help control erosion at each construction site. Because impacts from development projects, infrastructure projects, and flood facilities improvement projects would be temporary and short-term, and soil erosion would be localized, implementation of these projects would not result in a cumulatively considerable incremental contribution related to hydrology, groundwater recharge, water surface elevations, or water quality. The BA has been updated to include this additional information under the "Cumulative Effects" " section on pages 59-62.

Response to Comment 5

A hard copy of the DEIS/EIR was submitted to Howard Brown of NMFS on April 21, 2010. A hard copy of the Final EIR was provided to Mike Hendrick of NMFS on June 3, 2016. When the NEPA document is finalized, a hard copy of the Final EIS will be provided to NMFS, and an electronic copy will be available on the Sacramento District website.

Response to Comment 6

See above sections for inclusion of information and citation of relevant studies and reports, including species viability assessments for listed Central Valley fish species.

Response to Comment 7

Available literature indicates that limited Chinook salmon spawning typically occurs well upstream of the Project area. EFH in the San Joaquin River in the vicinity of the Project area consists of 1) adult and juvenile (smolt) Chinook salmon passage between upstream spawning grounds and the Pacific Ocean, and 2) limited in-channel rearing habitat for Chinook salmon juveniles: limited because it is situated in a reach of the San Joaquin River that is bound on both banks by levees, resulting in channel incision, and disconnected from its currently non-functioning floodplain. The river extends onto its floodplain only during high flood flows, and if fish are swept onto the disconnected floodplain during high flow conditions, they would likely become stranded due to the absence of secondary channels for returning flood flows to the river. The Project will result in improvement of EFH as functioning floodplain rearing habitat and improvement to existing EFH in the San Joaquin River channel, by reducing and reversing the effects of current channel incision in the immediate vicinity of Element IVc. Further, approximately 2.5 acres of SRA habitat will be created through re-vegetation and other restoration actions in Element IVc.

Levee degradation and floodplain grading activities in Element IVc will improve connectivity to the historic floodplain and improve habitat conditions in the floodplain. Although both actions will be constructed in dry conditions (above the high tide line), a potential short-term indirect effect of construction may be a temporary increase in sediment in the San Joaquin River, especially during the first storm or flooding event after construction. The erosion control and revegetation measures described in the "Avoidance and Minimization Measures" section in the BA are designed to reduce or capture any mobilized sediment resulting from the year's first rain or flooding event.

Any minor, temporary increase in fine sediment load as a result of this project would be un- measurable and overall negligible, especially when compared to the existing sediment load of the San Joaquin River. No adverse effects on EFH are expected, other than short-term and temporary effects to a comparatively small amount of edgewater habitat that is above the high tide line and characterized by ruderal vegetation. However, given the proposed avoidance and minimization measures, and specifically, BMPs that will be included as part of construction of the project, significant loss of EFH is not anticipated as a result of implementation of the Project. When completed, the project area will increase the amount and quality of EFH in the San Joaquin River floodplain for juvenile Chinook salmon rearing.

8. **Letter to USFWS, responding to request for additional information. October 7, 2016.**

October 7, 2016

RESPONSE TO U.S. FISH AND WILDLIFE SERVICE'S OCTOBER 2015 REQUEST FOR ADDITIONAL INFORMATION ON BIOLOGICAL ASSESSMENT

This is in response to U.S. Fish and Wildlife Service (USFWS) October 2, 2015, letter requesting additional information to support the request for initiation of formal consultation with the U.S. Army Corps of Engineers (USACE) on the Reclamation District 17 (RD 17) Phase 3 Levee Seepage Repair Project (Phase 3 Repair Project) in San Joaquin County, California. USACE had requested the initiation of Section 7 consultation in its February 27, 2015, letter; a copy of the Project's biological assessment (BA), dated February 2015, accompanied the USACE request. To respond to the USFWS request for additional information, we have bracketed the October 2, 2015, letter and have organized our responses accordingly.

Response to Comment 1

This memorandum provides a response to the USFWS' comments and addresses the information requests. The BA has also been revised, as appropriate, to address USFWS' information request.

Response to Comment 2

The BA (see "Compliance with USACE Vegetation Management Standards" [pages 19 – 20] and "Additional Project Components" [pages 27 – 28] subsections in the "Description of the Proposed Action" section) has been updated to reflect more specificity in RD 17's existing operations and maintenance (O&M) and vegetation management practices. As a result of construction of the Phase 3 Repair Project, landside vegetation would be removed; this was previously evaluated in the September 2011 Draft Environmental Impact Statement/Environmental Impact Report (DEIS/DEIR) (USACE and RD 17 2011) and is described in the "Direct and Indirect Effects on Listed Species in the Action Area" section of the BA. Long-term vegetation management practices, (post construction) for both landside and waterside vegetation, would be conducted in accordance with RD 17's existing practices, as described under the "Additional Project Components" subsection [pages 27 – 28] in the "Description of the Proposed Action" section of the BA, and are evaluated in the "Direct and Indirect Effects to Listed Species in the Action Area" section of the BA. These existing management practices associated with vegetation encroachments on the levees include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). See also Response to Comment 3.

Response to Comment 3

Information about Phase 3 Repair Project compliance with USACE's standards for vegetation management has been revised since the 2011 Draft EIS/EIR on the Phase 3 Repair Project. The BA (see "Compliance with USACE Vegetation Management Standards" [pages 19 – 20] subsection in the "Description of the Proposed Action" section) has been updated with the most current information contained within the forthcoming Final EIS which states the following in the section concerning "Waterside Vegetation Removal:"

> "With issuance of Engineering Technical Letter (ETL) 1110-2-571 in 2009, USACE updated its vegetation management standards for levees, requiring the removal of all vegetation, with the exception of perennial grasses, on levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2009a). In September 2011, USACE issued a Draft Environmental Impact Statement/Draft Environmental Impact Report (DEIS/DEIR) for the Phase 3 Repair Project (USACE and RD 17 2011). The September 2011 DEIS/DEIR considered two options for complying with ETL 1110-2-571, as follows:

- Full Implementation of USACE ETL 1110-2-571: All vegetation, other than perennial grasses, would be removed from the levee slopes and out 15 feet from the waterside and landside levee toes, or

- Acquisition of a Variance from Full Compliance with USACE ETL 1110-2-571: Permission would be obtained from USACE to retain all vegetation on the lower two-thirds of the waterside levee slope and out 15 feet from the waterside levee toe; all other levee vegetation still would be removed in accordance with USACE policy.

The USACE policy for Section 408 permission requires any proposed alteration must meet current USACE designs and construction standards. However a requester is not required to bring those portions or features of the existing USACE project that are not impacted by the alteration up to current USACE design standards. The requester has submitted construction methods where the waterside of the levee would not be affected by installation of the proposed alteration, so compliance with the ETL is not required for the approval of the Section 408 permission. RD17 is no longer considering full compliance with the ETL as an alternative.

RD 17 will continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which includes trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). In the Phase 3 Repair Project area, landside vegetation would be removed as previously evaluated in the September 2011 DEIS/DEIR (USACE and RD 17 2011) and as described under the "Additional Project Components" and "Effects" sections of this BA. Long-term vegetation management practices, for both landside and waterside vegetation, would be managed in accordance with the USACE O&M Manual which includes RD 17's existing practices, as described under the "Additional Project Components" section of this BA, and are evaluated in the "Effects" section of this BA."

The "Compliance with USACE Vegetation Management Standards" subsection [pages 19-20] in the "Description of the Proposed Action" section of the BA has been updated to reflect this change. Therefore, RD 17's existing vegetation management practices along the waterside of its levees will continue. These practices, which are also outlined in the BA's revised "Additional Project Components" subsection [pages 27-28] in the "Description of the Proposed Action" section, entail managing vegetation encroachments on the landside and waterside of the levee, through trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up 5 feet above the ground or 12 feet above the crown road. Some landside vegetation would be removed during construction of the Phase 3 Repair project. See also Response to Comment 2.

Response to Comment 4

See also Response to Comments 2 and 3. This Section 7 consultation is intended to cover both construction of the Phase 3 Repair Project and vegetation management along the levees post-construction. The BA (see "Compliance with USACE Vegetation Management Standards" and "Additional Project Components" sections) has been updated to reflect more specificity in RD 17's existing O&M and vegetation management practices. The "Direct and Indirect Effects to Listed Species in the Action Area" section in the BA has been updated as appropriate to account for ongoing and future vegetation management practices.

Following completion of construction, woody vegetation would not be allowed to establish on the new levee or within 15 feet of the toe of the levee. RD17 will continue to maintain the levees utilizing both mowing and herbicide application within the allowable work window. Rodent control will continue with baited rodenticide traps, and routine grouting will be used to manage burrows.

As stated in your October 2015 letter, the USFWS has not begun consultation on the Project yet, pending receipt of additional information (see Response to Comment 14); therefore, re-initiation is not necessary at this point.

Response to Comment 5

As reported in Table 8-2, no waterside woodlands would be directly affected (i.e., removed) during construction of the Phase 3 Repair Project. Per Response to Comment 3, after construction is completed, waterside vegetation would be managed in accordance with RD 17's existing practices, which are limited to trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up 5 feet above the ground or 12 feet above the crown road. Trees are only trimmed, not removed under existing O&M practices. Therefore, there is no change in the amount of waterside habitat that would be directly affected as a result of construction of the Phase 3 Repair Project or future vegetation management activities.

The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed as a result of construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed as a result of project construction (3.28 acres; see Table 8-2 in the BA) but none would be removed as a result of future vegetation management activities.

Response to Comment 6

The "Compensation Measures" subsection under the "Description of the Proposed Action" section on pages 332-33 of the BA has been updated to include new information about the Mitigation and Monitoring Plan. A Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project (Conceptual MMP) (RD 17 2016) has been prepared to describe the expansion and restoration of riparian habitat in Element IVc; this document is included as Appendix E to the BA.

This Conceptual MMP describes the proposed restoration of at least 10 acres of riparian scrub and Great Valley oak woodland habitat, located between the river and the waterside toe of the new setback levee in Element IVc. The "Direct and Indirect Effects to Listed Species in the Action Area" section of the BA has been updated to account for new detail in the habitat restoration proposal, and the analysis demonstrates that additional compensation sites would no longer be necessary to offset effects to species described in the BA.

Response to Comment 7

See Response to Comment 6. The "Riparian Brush Rabbit" subsection under the "Direct and Indirect Effects to Listed Species in the Action Area" section on pages 53-54 of the BA has been updated to account for new detail in the Conceptual MMP, and the analysis demonstrates that additional compensation sites would no longer be necessary to offset effects to species described in the BA.

Response to Comment 8

Effects to woody vegetation were evaluated through GIS analysis. Habitat layers were mapped into polygons. Where woodland clusters were within 20 feet of each other, the clusters were consolidated into one polygon. This clustering allowed for more than adequate buffer around woody vegetation, considering that the riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover rather than in large openings and that it seldom ventures more than 1 meter (3.3. feet) from cover (Sandoval et al. 2006; USFWS 1998).

See Response to Comment 6 and the "Riparian Brush Rabbit" subsection under the "Direct and Indirect Effects to Listed Species in the Action Area" section on pages 53-54 of the BA." The Conceptual MMP describes the proposed restoration of at least 10 acres of riparian scrub and Great Valley oak woodland habitat, located between the river and the waterside toe of the new setback levee in Element IVc. Using GIS and CAD analysis to guide habitat design, the acreage within the Element IVc levee setback area that can be planted with riparian vegetation was calculated. The calculation assumes the density of vegetation in the restored riparian habitat would be similar to the density of existing riparian vegetation on the northern side of Element Va.

Response to Comment 9

See Response to Comment 6. A Conceptual MMP (RD 17 2016) has been prepared to describe the expansion and restoration of riparian habitat in Element IVc; this document is now included as Appendix E to the BA. The Conceptual MMP outlines the proposed planting design, measurable objectives, monitoring, and management elements for the habitat restoration area.

Response to Comment 10

The "Compensation Measures" subsection under the "Description of the Proposed Action" section on pages 32-33 of the BA has been updated to state that elderberry shrubs that cannot be avoided would be transplanted to the levee setback area in Element IVc, in accordance with the USFWS's Conservation Guidelines for the valley elderberry longhorn beetle, and that the restoration design would include elderberry seedlings and associated species plantings to compensate for the effects to valley elderberry longhorn beetle habitat within the Phase 3 Repair Project site. The Conceptual MMP (RD 17 2016; Appendix E to the BA) describes the expansion and restoration of riparian habitat in Element IVc and outlines the proposed planting design, measurable objectives, monitoring, and management elements for the habitat restoration area.

Response to Comment 11

The Phase 3 Repair Project, and the associated USACE Section 404 and Section 408 actions, are limited to the construction of the Phase 3 levee repairs and ongoing vegetation management along the waterside and landside of the levees. The removal of landside vegetation, to accommodate construction of the Phase 3 Repair Project levee repairs, is discussed in the "Direct and Indirect Effects to Listed Species in the Action Area" section of the BA. Ongoing vegetation management is limited to vegetation trimming; no vegetation would be removed outside of construction. See also Response to Comments 2 and 3. RD 17 and USACE conduct ongoing monitoring to evaluate the maintenance of levee integrity.

Response to Comment 12

Additional future projects or actions may be necessary to achieve a 200-year level of protection. Levee repairs and improvements are subject to USACE Section 408 Permission and would require that USACE conduct Section 7 consultation with USFWS and NMFS. Thus, in the case that additional projects or actions are proposed, the USACE would be required to consult with USFWS to evaluate whether these could result in effects to federally listed species. The effects of projects that require a federal action are not considered in the cumulative effects evaluation during Section 7 consultation evaluation because they are subject to separate consultation (USFWS and NMFS 1998).

Response to Comment 13

The information about the exclusion of setbacks has been provided in the BA, with information specifically incorporated into the "Setback Levee Considerations" subsection of the "Description of the Proposed Action" section on page 22 of the BA. The complete hydraulic analyses that evaluated the setback levee alternatives are included as a new appendix to the BA (Appendix F).

As stated in the "Setback Levee with Seepage Berm and Underlying Cutoff Wall" section of the BA, and as described in greater detail under Section 2.1.4 in the Draft EIS/EIR (USACE and RD 17 2011), and in Appendix F to the BA, setback levees were considered but eliminated from further consideration in several project reaches for the following reasons.

- Construction of a setback levee along certain stretches of the river were hydraulically constrained and would have greatly increased the project scope to the point of being cost prohibitive (Elements VIa.4 and VIb).
- Because of the proximity to the bifurcation at Old River, the change in hydraulic conditions that would result from constructing a setback levee at Elements Va and VIa.1 at this location would increase flows down the San Joaquin River during flood events, which could lead to increased flooding downstream (Elements Va and VIa.1).
- Construction of a setback levee relative to other levee improvement alternatives and/or land acquisition to accommodate the construction of a setback levee was cost prohibitive (Elements Ie, IIIb, IVa, VIcde, and VIIb).
- Existing landside development constrained the option of constructing a setback levee (Elements Ia, IIab, VIIe, and VIIg).

Response to Comment 14

Acknowledged. This memorandum provides the additional information requested. The BA has also been revised, as appropriate, to incorporate this information.

INTRODUCTION

The purpose of this Biological Assessment (BA) is to review Phase 3 of the Reclamation District No. 17 (RD 17) Levee Seepage Repair Project (LSRP) (Phase 3 Repair Project) in sufficient detail to determine the extent to which the proposed action may affect any of the federally listed species described below under “Species Considered.” (See “Project Background and History” below for a brief summary of Phase 1 and Phase 2.)

RD 17, which is located in south-central San Joaquin County, California (**Exhibit 1**; see **Appendix A** for all exhibits), is responsible for maintaining 19 miles of levees along Walthall Slough, the San Joaquin River, and French Camp Slough, as well as the dryland levee along the southern boundary of Manteca. For discussion purposes, the RD 17 levees have been divided into 11 distinct “reaches,” identified by Roman numerals (i.e., I, II, III…, XI), and subdivided further into 28 “elements,” identified by the reach number followed by a lowercase letter and, where needed to further distinguish elements, an Arabic numeral (e.g., Ia, IIa, IIb, …, Va, VIa.1, VIa.2, VIa.4, …, VIe, VIIa, VIIb, …, VIIg…,XIa) (**Exhibit 2**).

This BA does not address the dryland levee (Reaches VIII – XI) because it is not a USACE flood risk management project, and therefore is not subject to Section 408 authorization. The dryland levee is an overland earthen berm, north and east of the San Joaquin River. Under almost all conditions, water does not come in contact with the dryland levee. It only functions as a flood risk management feature if water from the San Joaquin River or Walthall Slough leaves the banks of these waterways and inundates lands north and east, toward Manteca. The dryland levee then acts as an elevated earthen feature that prevents these flood waters from moving farther north. Suitable habitat for federally listed species does not occur along the dryland levee.

This BA has been prepared in accordance with requirements set forth under Section 7 of the federal Endangered Species Act (ESA) (16 United States Code [USC] 1536[c]). It supports formal consultation with the U.S. Fish and Wildlife Service (USFWS) and informal consultation with the National Marine Fisheries Service (NMFS) on the effects of the Phase 3 Repair Project on federally listed species and designated critical habitat. This BA also supports consultation with NMFS for project effects on Pacific Coast Salmon (*Oncorhynchus* spp.) essential fish habitat (EFH) , as required by the Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801). (See the “Essential Fish Habitat Assessment” section below.)

Section 7(a)(2) of the ESA directs federal agencies to ensure that their activities are not likely to jeopardize the continued existence of any listed species, or to result in the destruction or adverse modification of critical habitat. This section of the ESA also requires agencies with regulatory authority over listed species to issue biological opinions evaluating the direct and indirect effects of federal actions, and actions that are interrelated or interdependent with the federal action. The biological opinions must determine whether the actions being evaluated may appreciably reduce the listed species’ likelihood of surviving or recovering in the wild by reducing their productivity, numbers, or distribution.

To implement the Phase 3 Repair Project, RD 17 is requesting permission from the U.S. Army Corps of Engineers (USACE) for:

- alteration of federal project levees, pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408, referred to in this BA as “Section 408”); and
- placement of fill in jurisdictional waters of the United States, pursuant to Section 404 of the Clean Water Act (33 USC 1344, referred to in this BA as “Section 404”).

All Phase 3 Repair Project work occurring on the water side of the levee would be above the high tide line (HTL). Therefore, no additional authorizations under Section 10 of the Rivers and Harbors Act of 1899 are required.

These activities are described in more detail under “Description of the Proposed Action.” This BA analyzes direct, indirect, interrelated/interdependent, and cumulative effects of the proposed action on federally listed species.

SPECIES CONSIDERED

This document considers species that have been termed “threatened” or “endangered” under the jurisdiction of USFWS and NMFS. On February 27, 2014, biologists consulted the online database maintained by USFWS’s Sacramento Office to conduct a query of the Lathrop (462D) and West Sacramento (462A) 7.5-minute quadrangles (USFWS 2014) (**Appendix B**). Another query of the USFWS database was conducted on April 18, 2016 (USFWS 2016) (**Appendix B**), and the information in this BA was updated, based on those results. Using the California Department of Fish and Wildlife’s (CDFW’s) California Natural Diversity Database (CNDDB) (CDFW 2014) and the California Native Plant Society’s database of rare and endangered plant species (CNPS 2014), biologists also conducted a query of the topographic quadrangles in which the action area occurs (Lathrop and Stockton West) and the surrounding quadrangles; these database queries were conducted on February 27, 2014, and March 3, 2014, respectively (**Appendix B**). This query identified all listed species in the area surrounding the action area, which is defined here in accordance with ESA guidelines as “all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action” (50 Code of Federal Regulations [CFR] 402.02).

Based on these database queries and the biologists’ familiarity with local flora and fauna, 21 plant and wildlife species that are federally listed as endangered or threatened, or are federally proposed for listing were considered as part of this BA (**Table 1**).

The following federally proposed and federally listed species are known to occur or have the potential to occur in the Phase 3 Repair Project area (USFWS 2014, 2016):

- valley elderberry longhorn beetle (VELB) (*Desmocerus californicus dimorphus*),
- riparian brush rabbit (*Sylvilagus bachmani riparius*),
- delta smelt (*Hypomesus transpacificus*),
- Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*),
- longfin smelt (*Spirinchus thaleichthys*),
- Sacramento River winter-run Chinook salmon evolutionarily significant unit (ESU) (*O. tshawytscha*),
- Central Valley spring-run Chinook salmon ESU (*O. tshawytscha*), and
- the Southern DPS of North American green sturgeon (*Acipenser medirostris*).

The other federally listed species shown in Table 1 were eliminated from further consideration; they are not likely to occur in the Phase 3 Repair Project area because of a lack of suitable habitat, local range restrictions, regional extirpations, or lack of connectivity between areas of suitable or occupied habitat, or because the action area is located outside the extant range of the species (see “Action Area” section below). The USFWS and NMFS-regulated species with the potential to occur on-site are discussed in more detail in this BA.

Table 1
Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project

Species	Status	Habitat	Potential to Occur in the Lower San Joaquin River[1]
Plants			
Large-flowered fiddleneck *Amsinckia grandiflora*	Endangered[2] SJMSCP-covered[4]	Annual herb with bright orange, trumpet-shaped flowers that bloom in late spring. Historically found on north-facing slopes in the upper elevations of grasslands near the blue oak belt in Contra Costa, Alameda, and San Joaquin counties.	No potential to occur. No suitable habitat is present in the action area.[3]
Palmate-bracted bird's-beak *Cordylanthus palmatus*	Endangered[2]	Annual herb that blooms from late spring through summer. Grows on seasonally flooded, saline-alkali soils in lowland plains and basins at elevations of less than 500 feet. Known from scattered locations in Sacramento and San Joaquin valleys; however, unlikely to occur in San Joaquin County because of lack of alkali habitat.	No potential to occur. No suitable habitat is present in the action area.[3]
Invertebrates			
Conservancy fairy shrimp *Branchinecta conservatio*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	Threatened SJMSCP-covered[4]	Inhabits elderberry shrubs, primarily in riparian woodland and scrub habitat.	Could occur; elderberry shrubs present occasionally along the San Joaquin River on the waterside and landside of the Phase 3 Repair Project levee; however, no evidence of beetle exit holes was observed in these shrubs.
Vernal pool fairy shrimp *Branchinecta lynchii*	Threatened SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Vernal pool tadpole shrimp *Lepidurus packardi*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Fish			
Central Valley steelhead *Oncorhynchus mykiss*	Threatened	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Designated critical habitat is in the action area.
Central Valley fall/ late fall–run Chinook salmon *Oncorhynchus tshawytscha*	Species of Concern[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Essential fish habitat for this species is in the Phase 3 Repair Project area.

Table 1
Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project

Species	Status	Habitat	Potential to Occur in the Lower San Joaquin River[1]
Delta smelt *Hypomesus transpacificus*	Threatened[2] SJMSCP-covered[4, 5]	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears seasonally in inundated floodplains, tidal marsh, and the Delta.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin rivers, tributaries, and Delta. Although no spawning habitat is in the action area, delta smelt has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Longfin smelt *Spirinchus thaleichthys*	Candidate/ Proposed Threatened[2] SJMSCP-covered[4, 5]	Pelagic estuarine. Ranges from the Delta in California northward to the Cook Inlet in Alaska.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin rivers, tributaries, and the Delta. Although no spawning habitat is in the action area, longfin smelt has potential to occur in the San Joaquin River in the action area.[3]
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	Endangered[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. No spawning habitat is in the action area. Unlikely to occur in the San Joaquin River in the action area[3]; however, occasional adult and/or juvenile strays may be present.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	Threatened[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. Currently unlikely to occur in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. However, occasional adult and/or juvenile strays may be present. The SJRPP[6] includes the reintroduction of this species (an experimental population) to the San Joaquin River.
Green sturgeon *Acipenser medirostris*	Threatened SJMSCP-covered[4, 5]	Requires seasonally inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Amphibians and Reptiles			
California red-legged frog *Rana draytonii (=R. aurora draytonii)*	Threatened SJMSCP-covered[4]	Prefers semi-permanent and permanent stream pools, ponds, and creeks with emergent riparian vegetation and typically without predatory fish. Requires adequate hibernacula, such as small-mammal burrows and moist leaf litter.	No potential to occur. Potential aquatic habitat in the Phase 3 Repair Project area is limited to one constructed pond, likely with predatory fish, but the action area is outside the species' extant range.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
California tiger salamander *Ambystoma californiense*	Threatened[2] SJMSCP-covered[4]	In winter, breeds in vernal pools and stock ponds that are fish-free and inundated for a minimum of 12 weeks. In summer, aestivates in rodent borrows in grassland habitat.	Unlikely to occur. Potential aquatic habitat in the Phase 3 Repair Project area is limited to one constructed pond, likely with predatory fish; a small area of freshwater marsh in element Ib[7]; and agricultural ditches. Much of the action area consists of urban and agricultural land that is not suitable as potential upland habitat. A 1996 CNDDB record documents California tiger salamander adjacent to State Route 120 in roadside seasonal wetland; however, it is approximately 2 miles east of the San Joaquin River and geographically isolated.
Giant garter snake *Thamnophis gigas*	Threatened[2] SJMSCP-covered[4]	Streams, sloughs, ponds, and irrigation/drainage ditches; also requires upland refugia not subject to flooding during the snake's inactive season.	Unlikely to occur. Although potential habitat for this species is present in the Phase 3 Repair Project area, none of it is suitable. The only documented occurrences of giant garter snake are separated from the Phase 3 Repair Project area by extensive urbanized development (City of Stockton) and large rivers that do not provide suitable habitat and are a greater distance than the species is known to disperse. For additional information that summarizes the rationale that supports the "unlikely to occur" determination for this species in the Phase 3 Repair Project area, refer to **Appendix C** in this document.
Birds			
Least Bell's vireo *Vireo bellii pusillus*	Endangered[2]	Nests in riparian habitat adjacent to riverine and freshwater marsh.	Unlikely to occur. Although suitable habitat is present, the last recorded observation of this species in the action area was in 1878, with no extant occurrences.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	Threatened SJMSCP-covered[4]	Insect-feeder that forages in dense riparian oak forest canopy along major rivers. Species is considered extirpated from San Joaquin County.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Repair Project area, the action area is outside the species' extant range.
Mammals			
San Joaquin kit fox *Vulpes macrotis mutica*	Endangered SJMSCP-covered[4]	Annual grassland or grassy open stages with scattered shrubby vegetation; needs loose-textured sandy soils for burrowing, and suitable prey base.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Repair Project area, the action area is outside the species' extant range.
Riparian brush rabbit *Sylvilagus bachmani riparius*	Endangered[2] SJMSCP-covered[4, 5]	Inhabits riparian oak forest with dense understory of wild roses, grapes, and blackberries; small home ranges, seldom moving more than a few feet from cover, avoiding large openings in shrub cover and frequenting small clearings.	Known to occur. Occupied riparian habitat is present on the waterside of elements IIIa and IIIb, and suitable habitat is present immediately adjacent to the project area in several elements; the species also is known to occur on an oxbow between elements VIa.1 and VIa.4[7] and in waterside habitat between elements IIab and IIIa.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
Riparian (=San Joaquin Valley) woodrat *Neotoma fuscipes riparia*	Endangered SJMSCP-covered[4]	Requires healthy riparian forests, where it nests in cavities in trees, snags, or logs, spaces in talus, or lodges built of downed woody materials. Known to exist in and immediately adjacent to Caswell Memorial State Park, along the Stanislaus River in San Joaquin County.	No potential to occur. The action area is outside the species' extant range.

Notes: CNDDB = California Natural Diversity Database; Delta = Sacramento–San Joaquin Delta; Phase 3 Repair Project = Phase 3 of the proposed Reclamation District No. 17 Levee Seepage Repair Project; SJMSCP = San Joaquin Multi-Species Habitat Conservation and Open Space Plan; SJRRP = San Joaquin River Restoration Program

[1] **Potential for Occurrence Definitions:**

No potential to occur; Suitable habitat is not present in the Phase 3 Repair Project area and/or the Phase 3 Repair Project area is not within the historical or current range of the species.

Unlikely to occur: Potential habitat present, but species unlikely to be present in the Phase 3 Repair Project area because of current status of the species, a very restricted distribution, and/or essential habitat components are not present.

Could occur: Suitable habitat is available in the Phase 3 Repair Project area; however, few or no other indicators show that the species may be present.

Likely to occur: Habitat conditions, behavior of the species, known occurrences in the Phase 3 Repair Project area, or other factors indicate a relatively high likelihood that the species would occur in the Phase 3 Repair Project area.

Known to occur: The species, or evidence of its presence, was observed in the Phase 3 Repair Project area during reconnaissance-level surveys or was reported by others.

[2] These species have a similar status listing under the California Endangered Species Act, except for delta smelt and western yellow-billed cuckoo, which are both State-listed as endangered, and longfin smelt and San Joaquin kit fox, which are both State-listed as threatened.

[3] Action Area: The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project. Areas downstream from the Phase 3 Repair Project area may also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions.

[4] SJMSCP-covered: These species are covered under the SJMSCP (San Joaquin County 2000).

[5] SJMSCP-covered with limitations: The SJMSCP does not cover the conversion of occupied riparian brush rabbit habitat, limits the amount of delta smelt habitat, and does not authorize take of green sturgeon.

[6] See "San Joaquin River" subsection under "Environmental Baseline" section below, for more information.

[7] Elements: The RD 17 levees have been divided into seven distinct "reaches" identified by Roman numerals (i.e., I, II, III), and subdivided further into 19 "elements," identified by the reach number followed by a lowercase letter and, in some cases, an Arabic numeral (e.g., Ia, IIa, Va, VIa.1…); see **Exhibit 2**.

Sources: CDFW 2014; CNPS 2014; USFWS 2014, 2016; data compiled by AECOM in 2014 and updated by GEI Consultants in 2016

SPECIES HABITAT AND POTENTIAL FOR OCCURRENCE IN THE AREA

The following is a summary of relevant habitat conditions in the action area for species that could occur, are likely to occur, or are known to occur in the Phase 3 Repair Project area. Full species accounts for federally listed species addressed in this BA are presented in the section titled "Species Accounts."

- **Valley elderberry longhorn beetle:** Elderberry shrubs provide habitat for VELB. Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Repair Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Repair Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

- **Riparian brush rabbit:** Trapping conducted in February 2003 and February 2004 detected occurrences of riparian brush rabbit near the Phase 3 Repair Project area in waterside riparian habitat adjacent to elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1 and VIa.4 (CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004). The waterside habitat along elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The trapping locations between elements IIab and IIIa are dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The trapping locations between elements VIa.1 and VIa.4 are on an oxbow with dense riparian vegetation. Similar riparian habitat is present adjacent to the waterside of elements IIab, IVc, and Va. North of element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, or isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species.

- **Delta smelt:** Delta smelt are found from Suisun Bay upstream through the Sacramento–San Joaquin Delta (Delta). Delta smelt disperse widely into freshwater in late fall and winter as the spawning period approaches, and may move as far upstream as Mossdale on the San Joaquin River (Bennett 2005). Therefore, this species has the potential to occur in the Phase 3 Repair Project area.

- **Longfin smelt:** Longfin smelt occur in the Delta and tidally influenced segments of the Sacramento and San Joaquin rivers. The occurrence of longfin smelt in the San Joaquin River is rare, but it does occur on occasion when river salinity extends farther upstream, either because of Delta pumping or because of drought. Therefore, this species has the potential to occur in the Phase 3 Repair Project area.

- **Anadromous salmonids:** The action area (see "Action Area" section below) does not provide suitable spawning habitat for salmonids because it lacks the cold freshwater and gravel substrate characteristic of salmonid spawning areas in upper river basins. However, adult and juvenile Central Valley fall-run Chinook salmon and Central Valley steelhead could occur in the action area during migrations along the San Joaquin River and its tributaries. Winter-run and spring-run Chinook salmon are known to occur only in the Sacramento River and its tributaries (Moyle 2002). Because the action area is along the San Joaquin River, several miles upstream from its confluence with the Sacramento River, adult migrants along the Sacramento River are not expected to move into the action area. However, with implementation of the San Joaquin River Restoration Project (SJRRP) (see "San Joaquin River" subsection under "Environmental Baseline" below), an experimental population of spring-run Chinook salmon are being reintroduced to the San Joaquin River, initiated in 2014, to achieve one of the goals of the SJRRP, which is "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River…including naturally reproducing and self-sustaining populations of salmon and other fish" (NMFS 2013).

- **Green sturgeon:** Green sturgeon is known to occur in the San Joaquin River and Delta, and therefore, has the potential to occur in the lower San Joaquin River in the Phase 3 Repair Project area (Moyle 2002). Currently, green sturgeon spawning in the San Joaquin River is not documented.

CRITICAL HABITAT

"Critical habitat" is defined in Section 3(5)A of the ESA as the specific areas in the geographical area occupied by the species where physical or biological features are found that are essential to the conservation of the species and that may require special management considerations or protection. Specific areas outside the geographical area occupied by the species also may be included in critical-habitat designations, based on a determination that such areas are essential for conservation of the species.

The proposed action addressed in this BA would fall within designated critical habitat for delta smelt, which was designated on December 19, 1994 (59 Federal Register [FR] 65256). Critical habitat is designated to include most tidally influenced areas of the Delta.

The proposed action addressed in this BA would fall within designated critical habitat for the Central Valley steelhead DPS. Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin river basins, including the segment of the San Joaquin River in the action area (see “Action Area” section below).

The proposed action addressed in this BA would fall within designated critical habitat for the Southern DPS of North American green sturgeon. Critical habitat for green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

The action area is not within designated critical habitat for the remaining species listed in **Table 1,** for which such a designation has been made: large-flowered fiddleneck, Conservancy fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, VELB, Sacramento River winter-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, California red-legged frog, California tiger salamander, and least Bell’s vireo. Critical habitat has not been designated for palmate-bracted bird’s-beak, longfin smelt, Central Valley fall/late fall–run Chinook salmon ESU, giant garter snake, western yellow-billed cuckoo, San Joaquin kit fox, riparian brush rabbit, or riparian woodrat.

SAN JOAQUIN MULTI-SPECIES CONSERVATION PLAN

All of the above species, except the anadromous salmonid fish species, are covered on some level under the San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) (San Joaquin County 2000). The SJMSCP was developed to avoid, minimize, and mitigate impacts on plant and wildlife habitat projected to occur in San Joaquin County between 2001 and 2051, resulting from the anticipated conversion of open space land to non–open space uses. Ninety-seven species are covered by the SJMSCP. The plan is intended to provide comprehensive mitigation, in accordance with local, State, and federal regulations, for impacts of SJMSCP-permitted activities on these species. USFWS and CDFW participated in development of the SJMSCP, approved the mitigation, and agreed to issue incidental take permits for species and activities covered by the SJMSCP.

The geographic area covered in the SJMSCP extends up to the landside levee crown of the San Joaquin River levee and includes the Phase 3 Repair Project area. However, the SJMSCP does not cover federal flood risk management projects or activities that involve tidally jurisdictional wetlands or other waters of the United States, and thus the Phase 3 Repair Project would not be a covered activity under the SJMSCP. The SJMSCP outlines a mechanism by which a federal flood risk management project, such as the Phase 3 Repair Project, could obtain take coverage under the SJMSCP (see Section 8.2.3 of the SJMSCP). However, because the SJMSCP does not cover special-status fish, the conversion of riparian brush rabbit habitat, or impacts on other species on the waterside of the levee, RD 17 and USACE would not rely on the SJMSCP to assess and offset Phase 3 Repair Project effects on federally listed and State-listed species. Rather, through this BA and the associated Section 7 consultations with USFWS and NMFS, RD 17 and USACE would seek take authorization for Phase 3 Repair Project activities. Species listed under the California Endangered Species Act that also are covered species under the SJMSCP would be evaluated through coordination with CDFW.

CONSULTATION TO DATE

The list below summarizes correspondence, meetings, and discussions between regulatory agencies, RD 17, and consultants that relate to potential effects of the Phase 3 Repair Project on species addressed in this document. The most recent consultation is listed first.

4/18/2016 Letter from USFWS to GEI Consultants regarding the Species List for Phase 3–RD 17 Levee Seepage Repair Project (**Appendix B**)

10/2/2015 Letter from USFWS to USACE requesting additional information on the RD 17 Phase 3 Repair Project BA (**Appendix D-5**). A letter response to comments was completed by GEI Consultants and AECOM, on behalf of RD 17 (**Appendix D-6**).

7/7/2015 Letter from NMFS to USACE requesting additional information on the RD 17 Phase 3 Repair Project BA (**Appendix D-3**). A letter response to comments was completed by GEI Consultants and AECOM, on behalf of RD 17 (**Appendix D-4**).

2/27/15 Letter from USACE to NMFS transmitting the BA and requesting informal consultation.

2/27/15 Letter from USACE to USFWS transmitting the BA and requesting to initiate formal Section 7 consultation.

2/27/14 Letter from USFWS to AECOM regarding the Species List for RD 17 100-Year Levee Seepage Area Project[1] (**Appendix B**)

3/1/11 Tour of proposed action area with representatives from AECOM, USACE, USFWS, NMFS, and CDFW.

1/24/11 Meeting with representatives of USFWS and AECOM to discuss project permitting coordination, potential effects of the project on federally listed species, and development of a conservation strategy.

12/9/10 Meeting with representatives of CDFW and AECOM to discuss project permitting coordination, the potential effects of the project on State-listed species, use of the SJMSCP, and development of a conservation strategy.

8/24/10 Meeting with representatives of USACE, USFWS, NMFS, and AECOM to discuss the potential effects of the project on listed species and development of a conservation strategy.

6/11/10 Letter from NMFS to AECOM, responding to May 14, 2010, letter requesting technical assistance (**Appendix D-2**).

5/14/10 Letter from AECOM, prepared on behalf of RD 17, to USFWS and NMFS requesting informal technical assistance in evaluating the potential effects on listed species that could result from implementing USACE vegetation management standards, and in developing a conservation strategy to adequately offset the potential loss of habitat. Copies of the wetland delineation report and maps were provided with the letter (**Appendix D-1**).

---

1 "RD 17 100-Year Levee Seepage Area Project" is a reference to the RD 17 Levee Seepage Repair Project. This former name was used in documents published before preparation of the Final Environmental Impact Statement for Phase 3 of the RD 17 Levee Seepage Repair Project.

DESCRIPTION OF THE PROPOSED ACTION

U.S. ARMY CORPS OF ENGINEERS ACTION

RD 17, in cooperation with the California Department of Water Resources (DWR) and the Central Valley Flood Protection Board (CVFPB), is the local project sponsor for the Phase 3 Repair Project. RD 17 has requested permission from the CVFPB and USACE to alter segments of the San Joaquin River Levee System, which is a federal project levee. The proposed action for USACE is to make a permit decision on Phase 3 of the LSRP under the authority of Clean Water Act Section 404 and a permission decision under Section 408 of Title 33 USC. Under Section 408, USACE may allow the permanent use or occupancy of a USACE flood risk management project with approval by the Secretary of the Army on recommendation of the Chief of Engineers, provided that such use or occupancy would not be injurious to the public interest. USACE has determined that a Section 408 decision would be required for repair of seepage deficiencies to federal project levees. The activities requiring Section 408 and/or 404 authorizations, described in more detail below, include proposed alterations/repairs to USACE flood risk management facilities and fill of jurisdictional waters during earth-moving activities for levee construction. Activities for the Phase 3 Repair Project would be processed through an encroachment permit with the CVFPB. USACE would conduct a technical engineering review as part of the evaluation of the CVFPB's request to modify the Federal flood risk management project, in accordance with USACE regulations under 33 CFR 408.

PROJECT LOCATION

RD 17 is located in south-central San Joaquin County, California, in the center of the California Central Valley, at the north end of the San Joaquin River Basin, and within the far southeast limit of the Delta (see **Exhibit 1**). The boundaries of RD 17 are marked by French Camp Slough on the north, approximately 3 miles southwest of the central business district of the city of Stockton; the San Joaquin River on the west; Walthall Slough on the south (just below State Route 120); and Airport Way/McKinley Avenue on the east, just outside the city of Manteca. RD 17 is responsible for maintaining the levees along the east bank of the San Joaquin River from just south of Mathews Road to Walthall Slough, the levees along the north bank of Walthall Slough, and the dryland levee out to approximately South Airport Way (see **Exhibit 2**).

The proposed action is located along specific reaches of the RD 17 levees, as depicted in **Exhibit 2**. The Phase 3 Repair Project's landside levee improvements would include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system.

PROJECT BACKGROUND AND PURPOSE

PROJECT BACKGROUND AND HISTORY

The RD 17 system for reducing the risk of flood damage, like other flood protection systems in the San Joaquin Valley, initially was designed to facilitate agricultural development on the extensive valley floodplains and to support river navigation. Levees set closely along the rivers were designed to contain flows generated by common floods, and bypasses were constructed to carry overflows generated by large floods. The close-set levees ensured that water velocities would help scour the river bottom and move sediment through the system, reducing dredging costs for sustaining navigation. Starting in about 1863, RD 17 undertook the maintenance and reconstruction of the levee system.

Some of the levees in the Delta are considered "federal project levees." These levees were constructed or reconstructed (e.g., existing or damaged farm levees were improved) by USACE and are intended to meet federal standards. Construction of the federal levee system that encompasses the current RD 17 levees along Walthall

Slough, the San Joaquin River, and French Camp Slough began in 1944 and was completed in 1963. The levee system has since been upgraded substantially to meet Federal Emergency Management Agency (FEMA) requirements for flood protection during a 100-year flood event (flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability) [AEP]). In 1990, after extensive analysis, the RD 17 levees were accredited by FEMA as meeting the 100-year requirements for urban development.

During a high-water event on the San Joaquin River in January 1997, seepage and boils occurred at several locations along the RD 17 levees. USACE, DWR, and RD 17 successfully contained the seepage and boils, and the levees did not break. After the 1997 event, USACE, the CVFPB, and RD 17 funded a project, the Reconstruction of the California Central Valley Levees San Joaquin Basin #4, Reclamation District #17 Project, to repair the seepage and boil areas. The project was designed and constructed by USACE, and work was completed in 2003.

After reviewing the data supporting the 1990 accreditation and subsequent information, FEMA notified RD 17 of its intention to confirm full accreditation of the RD 17 levees as meeting FEMA's requirements for 100-year flood protection. On June 19, 2007, DWR wrote a letter to the City of Lathrop, with a copy to FEMA, stating that it could not support recertification of the RD 17 levees or the granting of provisional accreditation because of concerns about seepage exit gradients.[2] The basis of DWR's concern was analysis showing seepage exit gradients greater than 0.5, which indicated a higher likelihood of seepage or boils occurring during a high-water event Because of DWR's concern, FEMA then denied full accreditation and instead granted provisional accredited levee (PAL) status to the RD 17 levees. A PAL is a levee that FEMA has previously credited with providing a 100-year flood event level of flood risk reduction (i.e., flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability). In fall 2007, in response to the PAL status, RD 17 initiated a levee seepage repair program and requested funding through DWR's Early Implementation Program.

RD 17 subsequently implemented Phases 1 and 2 of the LSRP. After completion of the Phase 1 and 2 levee repairs, RD 17 submitted a recertification application to FEMA. In September 2010, RD 17 received a response letter declaring that FEMA had accredited the area protected by the RD 17 levee system, including the dryland levee, thereby removing the PAL status.

The Phase 1 Project included construction of two seepage berms, located in elements III and VI of the LSRP (**Exhibit 2**). The project reconstructed and extended the landside levee toe berms with earth and gravel fill, both landward and along the levee toe, to reduce seepage exit gradients. Work areas were designed to avoid any environmental resources of possible significance, including sensitive habitats and listed species. The project was determined to be categorically exempt from the California Environmental Quality Act (CEQA), and no federal authorizations or funding was required for the Phase 1 work; therefore, no National Environmental Policy Act (NEPA) analysis was triggered. The Phase 1 Project work was completed in January 2009.

The Phase 2 Project addressed work needed at nine levee reaches in the LSRP area. At eight of the nine reaches, the project involved constructing drained seepage berms along the landside levee toe. At one site that did not include seepage berm construction, RD 17 acquired an easement on land along the levee toe and performed various maintenance and site cleanup activities. A CEQA initial study/mitigated negative declaration that was completed for the Phase 2 Project concluded that no significant effects would occur on environmental resources after mitigation measures were implemented (RD 17 2009). Potential impacts on biological resources that resulted from Phase 2 Project implementation were mitigated through participation in the SJMSCP. No federal

---

2 "Seepage exit gradient" is an expression in numeric form of the potential for under seepage to exit on the landside of a levee as seepage or a boil. The lower the number used to express seepage exit gradient, the more resistant the system is to seepage or boils; the higher the number, the more likely seepage or boils may occur during a high water event. In formulas for seepage exit gradients, the numerator (top number in a fraction) typically addresses forces that cause or enhance seepage (e.g., water pressure), and the denominator typically addresses forces that resist seepage (e.g., soil resistance to water pressure, depth and weight of soil over the potential seepage area, distance from the levee toe). A lower seepage exit gradient (i.e., more resistance to seepage) is achieved when the numerator (positive seepage forces) is reduced and/or the denominator (resistance to seepage) is increased.

authorizations or funding was required for the Phase 2 work; therefore, no NEPA analysis was triggered. All Phase 2 Project work was completed in summer 2010.

PROJECT PURPOSE AND OBJECTIVES

The overall purpose of the Phase 3 Repair Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.3 miles of the approximately 19-mile RD 17 levee system, to reduce the risk of flooding in the RD 17 service area during a 100-year flood event. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation. USACE and RD 17 each view the project purpose from the purview of their respective responsibilities, defined as follows:

USACE's objectives for the Phase 3 Repair Project are to:

- decide whether or not to grant permission for the RD 17 Phase 3 Repair Project to alter the federal project levees within its levee system under Section 408, and
- decide whether or not to issue permits under Section 404.

RD 17's objectives for the proposed Phase 3 Repair Project are to:

- repair seepage deficiencies where needed to meet current USACE seepage criteria standards,
- increase the levee's resistance to under seepage and/or through seepage,
- provide under seepage exit gradients equal to or less than 0.5 at the landside levee toe, and equal to or less than 0.8 at the landside drainage seepage berm at the water surface elevation associated with the design water surface, and
- meet levee geometry requirements of the permitting agencies in the specific areas of repair work.

All Phase 3 Repair Project work would occur on the landside of the existing levee system or above the HTL, on the water side of the levee, therefore, authorization under Section 10 of the Rivers and Harbors Act of 1899 would not be required. Authorization under Section 404 of the Clean Water Act also would not be required on the landside work or on the water side of the levee because work would occur above the HTL. Section 404 authorization would be required on the land side of the levee. USACE verified a wetland delineation that was submitted for Phase 3 of the RD 17 LSRP on November 3, 2009 (a preliminary jurisdictional determination form was issued by USACE on November 10, 2009; USACE 2009b), and three supplemental wetland delineations were prepared. The first supplemental delineation was submitted on January 22, 2010 (a preliminary jurisdictional determination form was issued by USACE on April 9, 2010; USACE 2010a). The second supplemental wetland delineation was submitted on September 16, 2010 (a preliminary jurisdictional determination form was issued by USACE on October 7, 2010; USACE 2010b). The third supplemental wetland delineation was submitted on April 4, 2014 (a preliminary jurisdictional determination form was issued by USACE on April 7, 2014; USACE 2014a).

COMPLIANCE WITH USACE VEGETATION MANAGEMENT STANDARDS

With issuance of Engineering Technical Letter (ETL) 1110-2-571 in 2009,[3] USACE updated its vegetation management standards for levees, requiring the removal of all vegetation, with the exception of perennial grasses, on levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2009a). In September 2011, USACE issued a Draft Environmental Impact Statement/Draft Environmental Impact Report (DEIS/DEIR) for the

3 USACE ETL 1110-2-571 subsequently was replaced by ETL 1110-2-583 on April 30, 2014 (USACE 2014b).

Phase 3 Repair Project (USACE and RD 17 2011). The September 2011 DEIS/DEIR considered two options for complying with ETL 1110-2-571, as follows:

- Full Implementation of USACE ETL 1110-2-571: All vegetation, other than perennial grasses, would be removed from the levee slopes and out 15 feet from the waterside and landside levee toes, or

- Acquisition of a Variance from Full Compliance with USACE ETL 1110-2-571: Permission would be obtained from USACE to retain all vegetation on the lower two-thirds of the waterside levee slope and out 15 feet from the waterside levee toe; all other levee vegetation still would be removed in accordance with USACE policy.

The USACE policy for Section 408 permission requires any proposed alteration must meet current USACE designs and construction standards. However a requester is not required to bring those portions or features of the existing USACE project that are not impacted by the alteration up to current USACE design standards. The requester has submitted construction methods where the waterside of the levee would not be affected by installation of the proposed alteration, so compliance with the ETL is not required for the approval of the Section 408 permission. RD17 is no longer considering full compliance with the ETL as an alternative.

RD 17 will continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which includes trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). In the Phase 3 Repair Project area, landside vegetation would be removed as previously evaluated in the September 2011 DEIS/DEIR (USACE and RD 17 2011) and as described under the "Additional Project Components" and "Effects" sections of this BA. Long-term vegetation management practices, for both landside and waterside vegetation, would be managed in accordance with the USACE O&M Manual which includes RD 17's existing practices, as described under the "Additional Project Components" section of this BA, and are evaluated in the "Effects" section of this BA.

DESCRIPTION OF THE PROPOSED PHASE 3 REPAIR PROJECT

This section generally describes the elements of RD 17's proposed project. The section titled "Proposed Schedule and Sequence of Project Construction" describes construction, as well as the proposed construction schedule and sequencing. The Phase 3 Repair Project would address the under seepage and/or through seepage concerns raised by DWR and repair and/or remediate levee geometry to USACE design standards along approximately 5.2 miles of the RD 17 levee system, including portions of the San Joaquin River east levee and portions of the levee along the northerly bank of Walthall Slough. Under seepage occurs below the aboveground levee prism and is caused by the buildup of water pressure in the subsurface foundation soils when high-river stages are present on the waterside of the levees. This pressure head causes water to flow through the earthen foundation layers under the levee and exit onto the ground surface on the landside of the levee prism (**Exhibit 3**). Such seepage is not uncommon and does not inherently imply that the levee is failing; however, excessive and uncontrolled under seepage can carry fine-grained material with the water flow that can undermine the levee and lead to levee failure. Through seepage is the movement of water through the levee prism when high-river stage conditions exist on the waterside of the levee (**Exhibit 3**). Depending on the duration of high water and the permeability of the levee embankment soil, seepage may exit onto the landside slope of the levee, thereby negatively affecting the stability of the landside levee slope.

Levee improvements along the USACE project levees would consist primarily of in-place repair/remediation, but would include a single setback levee at element IVc. As summarized in **Table 2** and shown in **Exhibits 4a** through **4c**, the Phase 3 Repair Project's landside levee improvements would include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system. These levee repair components, as well as additional project components (such as levee geometry corrections and stormwater management), are described in more detail following **Table 2**. The proposed action does not include any work that would raise the existing levee. Limited work would be performed along the waterside of the levee above the HTL in element IVc, where the setback levee would be constructed.

LEVEE REPAIR ACTIVITIES

The Phase 3 Repair Project would include seepage berms, chimney drains, cutoff walls, a setback levee, and a raised landside grade. **Table 2** summarizes the activities proposed for each project element.

Table 2
Summary of Major Activities Proposed for Each Element of the Phase 3 Repair Project

Element	Type of Remediation	Proposed Activities
Ia	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and install a 590-foot-long seepage berm (minimum 65 feet wide) with chimney drain to meet required exit gradients.
Ib	under seepage and through seepage	Fill existing depression to 300 feet from toe of existing levee; place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width; and install a 125-foot-long seepage berm (minimum 60 feet wide) with chimney drain on top of fill to meet required exit gradients.
Ie, IIIb, IVa, and VIIb	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and construct seepage berms with lengths of 655 feet (Ie), 720 feet (IIIb), 525 feet (IVa), and 385 feet (VIIb), and chimney drains to meet required exit gradients. Minimum seepage berm widths would vary (65–105 feet) depending on the element. For element Ie, construct v-ditch from seepage berm to existing swale.
IIab	under seepage and through seepage	Install cutoff wall with a length of 2,550 feet to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.
IVc	under seepage and through seepage	Construct 1,240-foot-long setback levee with seepage berm and cutoff wall to meet required exit gradients. Depth of the cutoff wall will be 60 feet. Cutoff wall will involve degrading the top 1/3 to 1/2 of the levee crown and will begin with a 1:1 cut at the waterside crown. Seepage berm would be a minimum of 65 feet wide. Install riprap on waterside of existing levee above the high tide line where it would intersect setback levee. After setback levee is completed, remove 400 linear feet of the existing levee above the high tide line on the downstream side of oxbow. Grade approximately 8 acres of setback area, to drain to the river through the downstream opening in the remnant levee, and restore at least 9.9 acres, and up to 11.5 acres, of riparian scrub and Great Valley oak woodland in the area between the landside toe of the setback levee and the river. For more information about habitat restoration in element IVc, see the Conceptual Mitigation and Monitoring Plan for the Riparian Brush Rabbit in **Appendix E** of this document.
Va and VIa.1	under seepage and through seepage	Where feasible, place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and install cutoff walls with a length of 9,520 feet to meet required exit gradients. Depth of cutoff walls would vary from 60–85 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Open-cut method would be used for all cutoff walls.
IIIa	through seepage	Place levee fill material along landside of existing levee slopes where feasible to provide minimum 3:1 slopes and 20-foot levee crown widths and install chimney drain in existing 4,680-feet-long seepage berm to meet required exit gradients.

Table 2 Summary of Major Activities Proposed for Each Element of the Phase 3 Repair Project		
Element	**Type of Remediation**	**Proposed Activities**
VIa.4	under seepage and through seepage	Install cutoff wall with length of 70 feet to meet required exit gradients. Depth of cutoff wall would vary from 90–100 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 26-foot levee crown width.
VIb and VIcde	under seepage and through seepage	Install cutoff wall with length of 3,720 feet (VIb and VIcde) to meet required exit gradients. Depth of cutoff wall would vary from 70–80 feet. Cutoff wall in levee prism would involve both deep slurry mix construction as well as degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown.
VIIe	under seepage and through seepage	Install cutoff wall with a length of 1,900 feet to meet required exit gradients. Depth of cutoff wall would vary from 60–120 feet. Deep slurry mixing method would be used. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width. Soil removed during levee degradation would be stockpiled on adjacent RD 17 property and used for rebuilding the levee at these locations or used for fill at other locations in the Phase 3 Repair Project.
VIIg	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and construct seepage berm with chimney drain with length 395 feet to meet required exit gradients. Minimum seepage berm width would be 65 feet.
Source: Data provided by Kjeldsen, Sinnock & Neudeck, Inc. in 2014		

The respective levee improvement components are described next in more detail.

SEEPAGE BERMS

Reducing the risk of levee failure caused by under seepage and through seepage may be achieved by constructing a drained seepage berm. A drained seepage berm collects and conveys seepage, thereby reducing the flood risk associated with a high-water event. A drained seepage berm is built on the landside of a levee, and consists of layers of sand filter material, drain rock, geosynthetic filter fabric, and a seepage berm soil fill (**Exhibit 5**).

The drained seepage berm reduces flood risk during sustained high-river events by collecting seepage that otherwise would flow onto the landside ground surface at and beyond the levee's landside toe of slope, and then by conveying the seepage away from the levee. The layer of sand filter material placed on the natural ground surface serves to reduce the transmission of fine-grained soils into the drain rock, thereby maintaining the drain rock's ability to be a conductive soil unit that conveys collected seepage. Similarly, the filter fabric that separates the drain rock from the seepage berm fill soil prevents finer soils from migrating into the drain rock unit. The weight of the berm acts as ballast, reducing the potential for detrimental boils and piping.

The design width and height of a seepage berm are dependent on the relative permeability of the underlying soil layers and the amount of pressure head that push water under the levee and through these soils during sustained high-river events. The higher the water pressure head and the more dissimilar the porosity of the underlying soil layers, the wider and/or taller the seepage berm must be to prevent boils and reduce flood risk.

For the Phase 3 Repair Project, drained seepage berm widths of 65–120 feet are expected to be adequate to meet the design criteria in most cases (**Exhibit 5**). However, these types of berms may extend up to 300–400 feet inland from the landside toe of the levee. Seepage berms typically are constructed using select materials excavated from borrow sites or obtained from commercial sources. For the Phase 3 Repair Project, soil material for seepage berms would be purchased from commercial sources. A compacted-surface patrol road would be constructed near the outside edge of the seepage berm (see “Additional Project Components” below).

In urban areas, some seepage berms also would include a toe drain system (element VIIg) or a V-ditch (element Ie) to safely collect and discharge the seepage water into an urban storm drainage system. A toe drain pipe is a below-grade, perforated pipe surrounded by a layer of sand and drain rock (**Exhibit 6**). The toe drain pipe is a mechanism to safely collect and convey seepage water away from the levee and seepage berm. If the toe drain pipe is unable to convey the seepage water, the water exits the drained seepage berm through the drain rock at the face of the berm, similar to a nonurban berm.

CHIMNEY DRAINS

A chimney drain is a drainage system that collects seepage waters that are flowing through the aboveground portion of the levee structure. This type of drain is used to collect and convey through seepage. A chimney drain consists of a 1 to 3-foot-thick layer of sand and drain rock. Filter fabric is placed between the soil and rock layer to avoid migration of the soil into the rock, which can clog the rock layer and reduce its ability to carry seepage flows. The chimney drain is placed directly on the landside slope of the levee and tied into an existing or new drained seepage berm at the landside base of the levee (**Exhibit 7**). The chimney drain conveys the through seepage flows to a drained seepage berm, which is located at the landside base of the levee.

Installing a chimney drain in an existing drained seepage berm would include adding the through seepage material on top of the existing seepage berm and tying this material into the existing seepage berm material by removing the seepage berm fill material and physically tying the two drainage rock layers together. When the remediation includes construction of a new drained seepage berm with a chimney drain, the chimney drain would be installed during construction of the drained seepage berm.

CUTOFF WALLS

In selected locations of the Phase 3 Repair Project, cutoff walls would be placed through the levee prism (parallel to the river). Cutoff walls use specialized earthen materials (often bentonite clay, which has low permeability, or a mixture of bentonite and cement). Cutoff walls would be constructed vertically through the levee prism, extending into or through deeper foundational soils that have low-permeability (a layer through which seepage does not flow readily). Thus, cutoff walls would substantially reduce the potential for under and through seepage flow during high-river events. Two methods for installing cutoff walls would be used along portions of the RD 17 levees: the conventional open-trench method and the deep soil mixing method.

The conventional open-trench method would be used to install shallow cutoff walls to a maximum depth of approximately 80 feet. This method involves excavating material in an open trench (the trench is filled with a bentonite slurry to maintain the side slopes of the excavation) and then replacing it with the select materials, typically a bentonite or cement-bentonite slurry (**Exhibit 8**). In this case, the top one-third to one-half of the levee height is “degraded,” meaning that it is excavated so that any weakness in the narrow upper portion of the levee does not result in failure of the levee during construction.

For the deep slurry mixing method, specialized equipment (such as augers) is used to excavate deep into the subsurface, allowing the cutoff walls to reach depths up to 120 feet (**Exhibit 9**). The deep slurry mixing method involves mixing the soil in place with cement and / or bentonite, thereby reducing the risk of failure during construction. This method does not require levee crown degradation.

For the Phase 3 Repair Project, the cutoff walls would be extended approximately 300 feet beyond the element boundary to provide the required overlap when drained seepage berms have been or are being installed along the landside of adjacent levee elements. Levee slopes (where cutoff walls would be installed) also would be modified as needed to achieve the required 20-feet width and landside 3:1 slope.

Setback Levee with Seepage Berm and Underlying Cutoff Wall

General Description of Setback Levees

A setback levee is a levee constructed some distance behind an existing levee. The setback is tied into the existing levee at the upstream and downstream ends of the setback area. After certification of the setback levee, all or a portion of the existing levee between these two points typically is removed to allow high-water events to inundate the newly expanded floodway. Soil from the old levee may be used as a source of fill for other levee improvement projects, depending on the quality and quantity of material generated from demolition of the old levee. In some cases, it may be necessary to continue maintaining the existing levee after a setback levee is constructed (e.g., to protect existing development in the setback area) and to use the newly constructed levee as a backup levee.

General Description of Proposed Setback Levee and Associated Floodplain Restoration

Project Element IVc involves construction of a 1,240-foot-long setback levee with an underlying cutoff wall and a seepage berm, on a major oxbow of the San Joaquin River (see Table 2). A *Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project* (Conceptual MMP) (RD 17 2016) has been prepared to describe the expansion and restoration of riparian habitat in Element IVc; this document is included as an attachment to this BA (Appendix E).

In the Phase 3 Repair Project area, soil materials beneath a setback levee are anticipated to have properties similar to those of materials below the existing levees. Therefore, a setback levee would have no seepage-related benefit in the RD 17 area relative to other seepage control methods; like the existing levees, a setback levee would require either a cutoff wall or drained seepage berm to sufficiently reduce the potential adverse effects associated with under seepage flows (**Exhibits 10** and **11**). Nevertheless, implementation of a setback levee could provide some additional capacity in the river for floodwaters and also would have the potential to provide habitat in the area between the new and old levee locations. In the Phase 3 Repair Project area, any newly expanded floodway created by a proposed setback levee would be designed to drain surface water after a high-water event, to prevent fish stranding.

Setback Levee Considerations

As described in greater detail under Section 2.1.4 in the DEIS/DEIR (USACE and RD 17 2011), and consistent with Section 2.5.1 of the forthcoming Final Environmental Impact Statement (FEIS) (USACE *in prep.)* for the proposed project, setback levees were considered but eliminated from further consideration in several project reaches for the following reasons:

- Construction of a setback levee along certain stretches of the river would be hydraulically constrained and would greatly increase the project scope to the point of being cost prohibitive (elements VIa.4 and VIb).
- Because of the proximity to the bifurcation at Old River, the change in hydraulic conditions that would result from constructing a setback levee at these locations would increase flows down the San Joaquin River during flood events, which could lead to increased flooding downstream (elements Va and VIa.1).
- Construction of a setback levee relative to other levee improvement alternatives and/or land acquisition to accommodate construction of a setback levee would be cost prohibitive (elements Ia, Ie, IIIb, IVa, VIcde, and VIIb).
- Existing landside development would constrain the option of constructing a setback levee (elements IIab, VIIe, and VIIg).

The complete hydraulic analyses that evaluated the setback levee alternatives are included as **Appendix F**.

Tie-in to Existing Levee

Where the new setback levee would intersect the existing levee, the top one-third to one-half of the crown of the existing levee would be degraded beginning with a 1:1 cut at the existing waterside crown to facilitate tying the cutoff wall and setback levee into the existing levee.

Riprap

Approximately 0.64 acres (740 linear feet) of riprap would be installed only on the waterside of the existing levee and above the HTL in element IVc where it would intersect the setback levee. No trees/shrubs would be removed to place the riprap and any riprap around trees/shrubs would be hand-placed. The riprap would not be installed to act as launchable rock.

Remnant Levee Breach

After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 8 acres of floodplain to the river.

Floodplain Offset Area

The reconnected floodplain area would be graded to allow complete drainage of the floodplain to the river. The floodplain would be graded to drain to a central swale, approximately 2-feet deep. As flood flows recede, the swale would drain completely through the breach in the remnant levee. This would minimize the possibility of fish stranding. The periodic reactivation of floodplain rearing habitat for juvenile salmonids, in particular, and other native fishes as well would be a benefit to fish resources. The seasonal nature of inundation, along with complete drainage, would preclude establishment in the floodplain of predatory, non-native fishes.

The Conceptual MMP evaluates three breach invert elevations (8 feet [NAVD88], 10 feet [NAVD88] and 14 feet [NAVD88]) for the proposed levee breach on the downstream end of the oxbow. Hydraulic modeling, based on San Joaquin River flows as reported at the Vernalis USGS stream gage (Vernalis gage), about 17.5 miles upstream of the project area, was used to estimate the flow in the San Joaquin River at which water would enter the setback area through the remnant levee breach for the three breach invert elevations. The results are shown in Table 3.

To evaluate how often and how long the levee setback area would be expected to inundate, a review was made of the historical Vernalis gage daily flow records since the completion of New Melones Dam in 1979 (this represents a period where the San Joaquin River basin operating regime has been relatively unchanged). The evaluation used the mean daily flows for the period October 1, 1978 through September 30, 2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. Table 4 summarizes the estimated number and percent of days in the evaluation study period in which the levee setback area would flood based on the three invert elevations. Based on the historical data, the periods during which water would flow into the project breach at the three invert elevations are displayed in the figures below.

The appropriate breach elevation is under consideration and will be defined in the Final MMP. It is anticipated that the breach elevation would be set at approximately 9 or 10 feet (NAVD88). Approximately 1-2 acres of the floodplain would be set to an elevation of 14 feet (NAVD 88) or below and would inundate approximately every 6 years.

RAISED LANDSIDE GRADE

Directly adjacent to the landside toe of the levee in element Ib, an approximately 5-foot-deep depression was used as a borrow site to facilitate construction of the Howard Road Bridge. RD 17 would place fill within this depression to raise the landside grade.

Table 3 Estimated Flows for Inundation of the Element IVc Mitigation Site			
Breach Invert Elevation (feet, NAVD88)	Flow in San Joaquin River near Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Estimated Return Interval	Flow in San Joaquin River at Breach Location (cfs)
8	9,500	2 year	4,200
10	13,200	3 to 4 year	5,700
14	24,000	6 year	8,800
Note: cfs = cubic feet per second Source: MBK Engineers 2016			

Table 4 Estimated Total Duration of Mitigation Site Flooding for Evaluation Period of Record			
Breach Invert Elevation (feet, NAVD88)	San Joaquin River Flow at Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Number of Days Flow Equaled or Exceeded Since 10/1/1978	Percent of Days Flow Equaled or Exceeded Since 10/1/1978
8	9,500	1,619	12%
10	13,200	1,126	8.3%
14	24,000	423	3.1%
Note: cfs = cubic feet per second Source: MBK Engineers 2016			

ADDITIONAL PROJECT COMPONENTS

The following additional activities would occur as part of the Phase 3 Repair Project:

- **Levee geometry corrections:** Phase 3 Repair Project elements currently do not meet requirements for levee geometry (i.e., slopes, crown width). To correct levee geometry, levee fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot-wide levee crown. All elements would undergo some level of levee geometry corrections.

- **Operations and Maintenance (O&M) access and utility corridors:** A 20-foot-wide permanent O&M access corridor[4] would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.

- **Temporary construction easements:** Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the site(s) would be returned to pre-project conditions following completion of construction.

- **Stormwater /irrigation controls:** Drainage/irrigation swales would be constructed around the outside boundaries of levee repairs, where needed, and other stormwater best management practices (BMPs) would be implemented to manage stormwater runoff and/or irrigation during and after construction. These swales would be located so that they would not drain to/from wetlands or other waters of the U.S.

4 The CVFPB would require that a 20-foot-wide access corridor be established. However, on a case-by-case basis, effects on woody vegetation within this corridor may be avoided in place. However, for the purposes of the analysis in this FEIS, it was assumed that any vegetation within the 20-foot-wide corridor would be removed.

- **Right-of-way acquisition:** Lands within the Phase 3 Repair Project footprint would be acquired as needed, to accommodate levee repairs (e.g., seepage berms, setback levees) and establish the minimum 20-foot-wide O&M access corridor at the landside toes of all the improved levees, to prevent encroachment. Privately owned lands would be acquired in fee preferably, but may be taken as easements if needed. Where the project footprint overlies land owned and managed by other agencies (i.e., the City of Lathrop, San Joaquin County, Union Pacific Railroad [UPRR]), either the land would have to be acquired in fee or easements would have to be obtained and secured. Real property acquisition and any relocation services, if needed (although no relocations are anticipated), would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 USC 4601 et seq.) and implementing regulation, Title 49 of CFR Part 24, and California Government Code Section 7267 et seq.
- **Haul roads:** An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and cement) would be required to construct these levee improvements. These materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Phase 3 Repair Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would be public roadways, on and within 300 feet of the levees, existing unpaved roads used for access to work areas, and levee patrol roads atop the levee crown.
- **Landside vegetation removal:** Landside vegetation within the footprint of the proposed levee work, including maintenance roadway corridors and temporary access easements, would be cleared to prepare for levee repair work. The proposed action would involve performing limited work on the waterside of the levee above the HTL (e.g., installing riprap and degrading a portion of the levee in element IVc); however, no waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.
- **Encroachment management:** Several features, including power poles, vegetation, and a variety of agricultural-related facilities (e.g., irrigation infrastructure, fences), are within the Phase 3 Repair Project footprint. Utility infrastructure would be relocated as needed to accommodate the levee repairs, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Phase 3 Repair Project area would be removed or relocated as required to meet the criteria of USACE, the CVFPB, and FEMA. No waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.
- **Long-Term Vegetation Management:** Vegetation on the levees and within the access easements would be managed in accordance with current O&M practices to maintain access and visibility. These practices include: mechanical trimming of existing trees and removal of large dead and downed trees annually, as described under “Compliance with USACE Vegetation Management Standards”; regular summer and winter application of herbicides for weed control; and summer application of herbicides to control woody plants and berries.

PROPOSED SCHEDULE AND SEQUENCE OF PROJECT CONSTRUCTION

Construction of the Phase 3 Repair Project is scheduled to begin in 2017, and is expected to be completed by December 2018, assuming receipt of all required environmental clearances, permits, and approvals for implementation. Some related activities, such as relocating power poles, may be conducted before levee work is begun, and site restoration and demobilization could extend through spring 2019. The general levee construction window is seasonal (July 1–November 1), avoiding the period when high-water levels have the potential to occur within the San Joaquin River system. However, depending on hydrologic conditions and subject to compliance with species work windows, a work window variance that allows an extension outside the July 1–November 1 work period may be granted by the CVFPB. The CVFPB may stipulate that RD 17 has to comply with additional conditions and commitments as a component of any work window variance.

The proposed construction sequence, which would include concurrent work in several different elements to meet the project schedule, is as follows:

- **Relocation of power poles:** Power poles currently situated on the landside of the levee toe of some elements would need to be relocated to accommodate proposed drained seepage berms. To the extent feasible, power poles would be relocated beyond the toe of the new berm, outside the maintenance access easement. If placing poles on top of the seepage berms is required, either raised foundations or steel-reinforced concrete piers would be constructed to prevent the poles from affecting the seepage berms. RD 17 would oversee relocation of the power poles, in coordination with the appropriate utility and construction companies.

- **Site preparation at existing levee sites and in levee setback area:** Site preparation (i.e., clearing, grubbing, and stripping) of the levee elements would begin by clearing structures (see discussion in next bullet) and woody vegetation from the footprint of the proposed levee work and the permanent O&M access and utility corridors. Vegetation would be retained in areas adjacent to but outside the project footprint. This operation would require removal of some trees and relocation or removal of some elderberry shrubs. Large trees would be felled approximately 3 feet above ground level, with stumps temporarily left in place. Where feasible, small trees and elderberry shrubs would be relocated. Elderberry shrubs would be relocated, in accordance with the avoidance and minimization measures outlined (see "Avoidance and Minimization Measures – Valley Elderberry Longhorn Beetle" section of this BA). A minimal amount of belowground disturbance would occur. The clearing operation would be followed by grubbing operations to remove stumps, root balls, and any below-ground infrastructure. The area then would be disked to chop surface vegetation and mix it with near-surface organic soils. The disking operation would be followed by stripping the top 12 inches of earthen material from the landside slope of the existing levee and the footprint of the proposed seepage berms. Excess earthen materials (i.e., organic soils, and excavated material that does not meet levee embankment criteria) would be temporarily stockpiled and then would be re-spread on the surface of the new levee slopes and seepage berms, provided this material is not contaminated with vegetation. Any stripped material contaminated with vegetation and other debris generated during the clearing and grubbing operations would be hauled off-site to a suitable landfill.

- **Removal or modification of landside structures and other facilities:** In a few levee elements, agricultural facilities (e.g., fences, drainage infrastructure) or parking lots are located within the footprint of the proposed levee work. These facilities would be removed from or relocated outside the project footprint before levee construction begins in those areas. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Demolished concrete could be sent to a concrete recycling facility. If any wells or septic systems would be affected, they would be abandoned in accordance with the applicable State and County requirements.

- **Construction of the setback levee with drained seepage berm and underlying cutoff wall:** Construction of the setback levee embankment in element IVc would begin as soon as sufficient lengths of levee foundation are prepared and weather conditions are suitable. Foundation preparation would include constructing a levee keyway that would be excavated 3–5 feet deep across the entire footprint of the proposed setback levee. A smaller but deeper excavated inspection trench, centered beneath the new waterside hinge point of the setback levee, then would be constructed beneath a small portion of the keyway to meet DWR standards. After the foundation layers are backfilled with engineered soil, a geotechnical geogrid fabric would be installed at ground level across the entire setback levee footprint. A second layer of geogrid fabric would be placed at mid-height of the new levee fill section to further reduce the potential for post-construction settlement of the new levee. The embankment would be constructed of engineered fill, with the fill placed in 3-foot-maximum lifts by motor graders. Each lift would be moisture-conditioned using water trucks and would be compacted to the specified density using a suitable compactor, such as a sheep's foot, tamping foot, or rubber-tired roller. Next, quarry stone riprap would be applied in three segments, to armor the newly completed setback levee's waterside slope and protect against erosion. Riprap would be placed on the waterside levee above the HTL in areas that are characterized by ruderal land cover (**Exhibit 12**). All waterside woodland would be avoided; all waterside trees would be avoided as well as any tree canopy that

overlaps riprap. Riprap placement would be done either by barge or by long-arm excavator from the top of the levee crown. Riprap dimensions for the three segments are: 340 feet long by 50 feet wide (0.39 acre), 140 feet long by 30 feet wide (0.096 acre), and 230 feet long by 50 feet wide (0.26 acre). A drained seepage berm then would be constructed on the landside of the setback levee. Fill material for setback levee and drained seepage berm construction would be obtained from commercial sources and would be delivered to levee construction sites using haul trucks.

- **Setback levee site restoration and demobilization:** After completion of construction, the previously stripped topsoil material would be placed on top of the completed setback levee and associated seepage berms in element IVc, and levee slopes and the tops of the seepage berms would be hydroseeded. An aggregate-base patrol road would be constructed at the landside edge of the seepage berm and setback levees and on the new setback levee crown. The existing levee would be fully restored at the tie-in points to the new setback levee. The existing levee crown patrol road would be redressed with aggregate base, to restore it to preconstruction levels. Any disturbed riprap also would be supplemented to provide a uniform layer across the connection point with the new setback levee. Immediately after final construction, the setback levee’s fill slopes would be covered with erosion control material until application of the hydroseed. Any construction debris would be hauled to an appropriate off-site waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization would be likely to occur in various locations as construction proceeds along various elements.

- **Removal of existing levee at setback levee elements, site restoration, and demobilization:** After certification of the new setback levee and seepage berm in element IVc, a 400-linear-foot-long section of the existing outboard levee (which is approximately 2,400 linear feet long in element IVc) on the downstream side of the existing oxbow would be partially degraded. The area where the levee would be degraded is characterized by ruderal land cover (**Exhibit 13b**); some landside vegetation would be removed (as accounted in the “Effects – Direct and Indirect Effects on Species in the Action Area” section of this BA, but all waterside trees and overlapping tree canopy would be avoided. At least 9.9 acres (and up to 11.5 acres) of riparian vegetation would be established in the area between the new setback levee and the river (**Exhibit 12**) (see the “Compensation Measures” section below for additional information). This acreage would be made up of approximately 0.5 acre of floodplain swale and approximately 4.5 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee; approximately 2.5 acres of enhanced riparian scrub habitat between the river and the waterside toe of the existing levee; and approximately 4 acres of restored Great Valley oak woodland/upland refugia habitat along the existing levee. These acreages would include approximately 1.6 acres of contingency, with the goal of restoring a minimum of 9.9 acres of riparian habitat. This work would be completed after flood season (from July 1 through November 1) and above the HTL, primarily using scrapers, excavators, and bulldozers to remove the levee section and all present levee encroachments.

- **Construction of drained seepage berms, drained seepage berms with chimney drains, and chimney drains within existing drained seepage berms:** Fill material for levee improvements would be obtained from commercial sources and delivered to the levee construction sites by haul trucks. The material then would be spread by motor graders and compacted by sheep’s foot rollers to build new seepage berms and seepage berms with chimney drains. A water truck would be used to properly moisture-condition the soils for compaction. Installing the chimney drains in existing drained seepage berms also would require use of an excavator or scraper to remove the existing drained seepage berm fill material so that the chimney drain fill material can be tied into the drainage rock layer of the existing drained seepage berm.

- **Construction of cutoff walls:** Cutoff wall construction is anticipated to occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance, when necessary. Lights and possibly power generators would be used during nighttime construction hours. Additional equipment would include slurry batch plants to prepare bentonite or bentonite cement mix, pumps, and support vehicles. Four to five batch plants or slurry ponds would be required for the project; these would be located near the site of cutoff wall construction. Each batch plant or slurry pond with associated pumps and support equipment would occupy an area of approximately 100 square feet that would be restored to pre-project conditions following completion of cutoff wall construction. Cutoff walls may be installed concurrently in two or more different directions within an element. RD 17 proposes to use the deep slurry mix method for installing deep cutoff walls, which would avoid the need to degrade the top of the levee, and conventional slurry trench walls (open-cut method) for shallow cutoff walls. RD 17 also would consider driving sheet piles, using a drop impact hammer or other pile-driving technology in lieu of cutoff wall installation at element VIIe. The number of cutoff wall rig setups would depend on the project schedule and contractor preference. Each deep slurry mix cutoff wall rig would move continuously along the proposed alignment, to attain an uninterrupted cutoff wall and reduce prolonged disturbance to residences near some cutoff wall segments. Each cutoff wall rig could move 50 to 100 feet horizontally during a 12-hour work shift, while each conventional slurry trench rig could move 75 to 200 feet horizontally during a 12-hour work shift. Disturbances to nearby residences are expected to be minor because of the limited number of residences near the cutoff wall installation areas. However, where lights, noise, and/or vibration would exceed allowable nighttime standards for the applicable local jurisdiction, work hours would be restricted to daytime work hours.

- **Traffic control during construction:** Traffic control and detours could be required in the immediate vicinity of some levee improvements. Traffic control measures would include flaggers for one-way traffic control, advance construction signs and other public notices to alert drivers to activity in the area, and “positive guidance” detour signage on alternate access roads to reduce inconvenience to the driving public. Detours for through traffic are not likely to be required.

- **Site restoration and demobilization:** On completion of construction, previously stripped topsoil material not contaminated with vegetation would be placed on top of the completed seepage berms and any disturbed levee slopes. Any previously nonagricultural, vegetated areas disturbed during construction would be hydroseeded with a standard erosion control mix. An aggregate-base patrol road would be constructed at the landside edge of any seepage berms. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization likely would occur in various locations as construction proceeds along various elements.

AVOIDANCE AND MINIMIZATION MEASURES

GENERAL

A qualified biologist, retained by RD 17, will be on-site to ensure compliance with the avoidance and minimization measures described below, particularly where construction activities occur adjacent to sensitive habitats to be avoided.

A worker awareness training program will be conducted for construction crews before the start of construction. The program will include a brief overview of special-status species and sensitive resources (including riparian habitats) in the Phase 3 Repair Project area, measures to avoid and minimize effects on those resources, and conditions of relevant regulatory permits.

Furthermore, traffic speeds on unpaved roads will be limited to 15 miles per hour, to reduce dust emissions and minimize potential effects on listed species, such as the riparian brush rabbit.

VALLEY ELDERBERRY LONGHORN BEETLE

For elderberry shrubs that are located in the Phase 3 Repair Project area, RD 17 will implement the following avoidance and minimization measures that are described in the Conservation Guidelines for the Valley Elderberry Longhorn Beetle (VELB Guidelines; USFWS 1999), to avoid and minimize effects on VELB:

- All elderberry shrubs that are located adjacent to construction areas but can be avoided will be protected by establishing a fenced avoidance area. The fencing will be placed at least 20 feet from the dripline of the shrubs. All elderberry shrubs to be protected during construction will be identified and marked by a qualified biologist. Orange construction barrier fencing will be placed at the edge of the respective buffer areas, and no construction activities will be permitted within the buffer zone other than those activities necessary to erect the fencing. In cases where the elderberry dripline is less than 20 feet from the work area, k-rails will be placed at the shrub's dripline to provide additional protection to the shrubs from construction equipment and activities. Temporary fences around the elderberry shrubs and, where appropriate, k-rails at shrub drip lines will be installed as the first order of work. Buffer area fences around elderberry shrubs will be inspected weekly by a qualified biologist during ground-disturbing activities, until adjacent project construction is complete or the fences are removed on approval by a qualified biologist and the resident engineer.

- No insecticides, herbicides, or other chemicals that may harm the beetle or its host plant will be used within 100 feet of elderberry shrubs.

- Elderberry shrubs that require removal will be transplanted to a USFWS-approved site during the dormant period for elderberry shrubs (i.e., November 1 to February 15) and in accordance with the VELB Guidelines (USFWS 1999).

- Each elderberry stem measuring 1 inch or greater in diameter at ground level that may be adversely affected (i.e., transplanted) will be replaced with elderberry seedlings and seedlings of associated species, in accordance with the VELB Guidelines (USFWS 1999).

Regarding provision for off-site compensatory mitigation for habitat losses, see the "Compensation Measures" section below.

RIPARIAN BRUSH RABBIT

The following measures will be implemented to avoid and minimize potential adverse effects on riparian brush rabbit in potential habitat within and adjacent to the Phase 3 Repair Project footprint (i.e., Great Valley cottonwood and Great Valley oak riparian forest communities):

- Potential riparian brush rabbit habitat will be identified and avoided wherever possible. The primary engineering and construction contractors will ensure, through coordination with a qualified biologist who is pre-approved by USFWS and retained by RD 17, that construction will be implemented in a manner that minimizes disturbance of such areas to the extent feasible.

- Temporary fencing will be used during construction to prevent disturbance of potential habitat adjacent to construction areas. Construction personnel, vehicles, and equipment will remain within the identified construction area. In addition, a silt fence or other suitable temporary barrier will be installed around the construction area where it borders suitable habitat for brush rabbits, to exclude brush rabbits from the construction site; this silt fence or temporary barrier either will be incorporated into the temporary fencing or will be installed as a separate fence. Temporary signage will be placed along the rabbit exclusion fence at 150-foot intervals, warning contractors to stay within the construction area. The temporary rabbit exclusion fence and associated signage will be inspected by a qualified biologist and the construction contractor each morning before the beginning of construction activities, and will be repaired and maintained as necessary. A biological monitor will inspect the fence at least once a week. The temporary rabbit exclusion fence and signage will be removed after construction activities are no longer occurring adjacent to the exclusion area.

- Where suitable habitat for riparian brush rabbit has to be removed, vegetation will be removed by hand 2 weeks before the start of construction so that no riparian brush rabbits are present in the construction area at the time of construction. A qualified biologist, retained by RD 17, will be on-site during vegetation removal.

Areas of temporary habitat disturbance in the Phase 3 Repair Project area will be revegetated with native plant species and restored to pre-project conditions.

Regarding provision for on-site compensatory mitigation for habitat losses, see the "Compensation Measures" section below.

FEDERALLY LISTED FISH—DELTA SMELT, LONGFIN SMELT, ANADROMOUS SALMONIDS, AND GREEN STURGEON (WATER QUALITY)

The following measures will be implemented to avoid and minimize potential adverse effects on water quality:

- Any work within the existing floodway (i.e., placing riprap on the waterside levee above the HTL at element IVc) of the San Joaquin River will not take place during the designated flood season (i.e., November 1 to July 1) and will not begin until evaluation of upstream conditions (e.g., reservoir storage and snowpack) indicate that inundation of these areas will be unlikely to occur during construction.
- RD 17 will comply with all local, State, and federal regulations and environmental requirements regarding turbidity-reduction measures, including the following:
    - obtaining and complying with relevant agency permits (e.g., CDFW streambed alteration agreement, Central Valley Regional Water Quality Control Board [RWQCB] Clean Water Act Section 401 certification, and Section 404 permit);
    - developing and implementing a storm water pollution prevention plan (SWPPP) that identifies specific BMPs to avoid and minimize effects on water quality during construction activities; and
    - complying with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity.
- RD 17 will file a notice of intent with the Central Valley RWQCB to discharge stormwater associated with construction activity. Final design and construction specifications will require implementation of standard erosion, siltation, and good housekeeping BMPs. Construction contractors will be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for construction activity (Order No. 2009-0009-DWQ or the current permit in place at the time of construction). The SWPPP will describe the construction activities to be conducted, BMPs that will be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that will be conducted.

  At a minimum, the following specific BMPs will be implemented:

    - All work will be conducted according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized.
    - Silt fences and/or straw wattles will be installed near riparian areas or existing drainages to control erosion and trap sediment and reseed cleared areas with native vegetation.
    - Maintenance will be conducted on a regular basis to ensure proper installation and function of BMPs, and during storm events, maintenance will be conducted daily.
    - BMPs that have failed (within 48 hours of an event) will be repaired and replaced immediately with sufficient devices and materials (e.g., silt fence, coir rolls, and erosion blankets), provided throughout project construction to enable immediate corrective action for failed BMPs.

- Stockpiling of construction materials (e.g., portable equipment, vehicles, and supplies, including chemicals) will be restricted to designated construction staging areas, exclusive of any riparian, wetland, or other areas supporting waters.
- Disturbed soils at construction areas will be stabilized before the onset of rainfall.
- Stockpiles will be stabilized and protected from exposure to rain and potential erosion.

The SWPPP also will specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of effects from use or accidental spills or releases of contaminants. Specific measures applicable to the project will include the following:

- Compliance will be required by RD 17 contractors with all applicable State Water Resources Control Board (SWRCB) and Central Valley RWQCB standards and other applicable water quality standards.
- Strict on-site handling rules will be developed and implemented, to keep potentially contaminating construction and maintenance materials out of drainages and other waterways.
- When refueling and servicing equipment, absorbent material or drip pans will be used underneath such equipment to contain spilled fuel, oil, and other fluids; and any fluid drained from machinery will be collected in leak-proof containers and deliver to an appropriate disposal or recycling facility.
- Controlled construction staging and fueling areas will be maintained at least 100 feet away from channels or wetlands, to minimize accidental spills and runoff of contaminants in stormwater.
- Substances that can be hazardous to aquatic life will be prevented from contaminating the soil or entering watercourses.
- Spill cleanup equipment will be maintained in proper working condition. All spills will be cleaned up immediately according to the spill prevention and response plan, which will be prepared by RD 17 or its contractor or representative and will be approved by the RWQCB before the start of project ground-breaking.
- NMFS, USFWS, CDFW, and the Central Valley RWQCB will be notified immediately (within 24 hours) of any reportable spills and cleanup occurrences. All such spills, and the success of the efforts to clean them, will be recorded in post-construction compliance reports.
- A slurry spill contingency plan will be developed, which will be prepared by RD 17 or its contractor or representative before the start of project groundbreaking, to respond to a potential for bentonite slurry spill and prevent slurry from entering watercourses.
- Construction materials handled by RD 17 or its contractors will be stored and transported in a manner that minimizes potential water quality effects. Storage areas will be located away from drainages and waterways, outside the floodplain, and away from sensitive resources, and containment facilities will be used.

BMPs will be applied to meet the “maximum extent practicable” and “best conventional technology/best available technology” requirements and address compliance with water quality standards. RD 17 will implement a monitoring program during and after construction so that the Phase 3 Repair Project complies with all applicable standards and BMPs implementation is effective.

COMPENSATION MEASURES

VALLEY ELDERBERRY LONGHORN BEETLE

As described above under "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle," compensation for effects on VELB will be provided in accordance with the VELB Guidelines (USFWS 1999). Elderberry shrubs that cannot be avoided will be transplanted to the levee setback area in element IVc (**Exhibit 12**). The restoration design, as outlined in the Conceptual Mitigation and Monitoring Plan for the Riparian Brush Rabbit (Conceptual MMP; **Appendix E**), will include elderberry seedlings and associated species plantings to compensate for the effects on VELB habitat in the Phase 3 Repair Project site. Transplanting unavoidable elderberry shrubs and planting elderberry seedlings and associated species (in an amount determined through compliance with the VELB Guidelines) will fully compensate for the loss of VELB habitat resulting from construction activities associated with the Phase 3 Repair Project.

RIPARIAN BRUSH RABBIT

Compensation for effects on riparian brush rabbit habitat will consist of restoring natural habitats in the Phase 3 Repair Project area.

As described in more detail in the Conceptual MMP (**Appendix E)**, on-site compensation for adverse effects on riparian brush rabbit habitat will include restoration of at least 9.9 acres of riparian habitat in the proposed levee setback area in element IVc. This acreage will be made up of approximately 0.5 acre of floodplain swale and approximately 4.5 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee; approximately 2.5 acres of enhanced riparian scrub habitat between the river and the waterside toe of the existing levee; and approximately 4 acres of restored Great Valley oak woodland/upland refugia habitat along the existing levee. The total of amount of potential compensatory mitigation acreage is approximately 11.5 acres, which will allow approximately 1.6 acres of contingency to achieve the compensation for riparian brush rabbit habitat.

After the new setback levee is constructed and certified in element IVc, a small 400-foot section of the existing levee will be partially degraded. Native riparian scrub vegetation will be established within the entire setback area floodplain. Species in the plant palette will be those preferred by the riparian brush rabbit for providing cover, including: California blackberry (*Rubus ursinus*), California wild rose (*Rosa californica*), sandbar willow (*Salix exigua*), coyote brush (*Baccharis pilularis*), and golden currant (*Ribes aureum*), among others. Understory vegetation will include herbaceous species that have been identified as preferred forage by the riparian brush rabbit, such as mugwort (*Artemisia douglasiana*) and gumplant (*Grindelia camporum*). To provide refugia during flood events, the old levee footprint also will be vegetated with riparian scrub and riparian woodland tree species. The upland refugia will include elderberry seedlings and associated species plantings to compensate the effects on VELB habitat in the Phase 3 Repair Project area. In addition to plantings within the setback area, waterside riparian vegetation will be enhanced with plantings in open areas.

Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4.5 acres of ruderal grassland that can be restored as riparian scrub habitat (**Exhibit 12**). Approximately 2.5 additional acres of riparian scrub habitat will be restored and/or enhanced between the waterside toe of the existing levee and the river. The restored riparian scrub habitat will consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee will remain in place and approximately 4 acres of Great Valley oak woodland will be established on it, thus providing upland refugia for the riparian brush rabbit during high-water events.

Approximately a 3:1 restoration to impact mitigation ratio (for effects on potential riparian brush rabbit habitat) will be accomplished in the restoration area, with approximately 9.9 acres (and up to 11.5 acres) of riparian brush rabbit habitat restored. The expansion and restoration of riparian habitat in element IVc will augment the waterside riparian corridor along the San Joaquin River and will provide additional riparian habitat for the riparian brush rabbit between two known occurrences of this species (i.e., between elements IIIa/IIIb and elements VIa.1/VIa.4 [CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). The restoration area will be contiguous with existing waterside riparian habitat along element IVc; this waterside riparian habitat along element IVc extends northward through elements IVa, IIIa, and IIIb, and southward through elements Va and VIa.1. Documented occurrences exist of riparian brush rabbit in the waterside riparian habitat in elements IIIa and IIIb, and north of element IIIa and south of element VIa.1; therefore, reestablishing and protecting riparian habitat in element IVc will provide expanded and connected habitat for this species. This habitat creation and enhancement will fully compensate for the loss of habitat for riparian brush rabbit resulting from construction activities associated with the Phase 3 Repair Project.

MITIGATION AND MONITORING PLAN

A Conceptual MMP has been prepared to describe the expansion and restoration of riparian habitat in element IVc (**Appendix E**). Specifically, this plan:

- describes specifications for the restoration of habitat components, including details about the restoration of riparian habitats, with a list of the plant species and drawings/designs to show the location of the plant species and planting density;
- establishes specific success criteria for the habitat components, including:
  - performance standards to determine whether the habitat improvement was trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions);
  - monitoring and maintenance protocols; and
  - measureable goals to ensure vegetation survival to provide and replace riparian habitats;
- specifies remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring); and
- describes short and long-term management and maintenance of the habitat lands.

The Conceptual MMP is intended to be developed into a Final MMP, in coordination with USFWS, NMFS, and USACE, and would be reviewed and approved by USFWS and NMFS before ground-breaking in the portions of the Phase 3 Repair Project area that could affect the species addressed in this BA. RD 17 would provide conservation of the restored riparian habitat in the levee setback area in element IVc. The compensation habitat ultimately would be transferred to a suitable land management organization, for long-term management and monitoring. This habitat creation and enhancement would fully compensate for the loss of habitat for VELB and riparian brush rabbit resulting from construction activities associated with the Phase 3 Repair Project.

ACTION AREA

The action area is defined in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project.

Areas downstream from the Phase 3 Repair Project area also may be indirectly affected by the flood risk management component of the project, through improved water quality and flood risk management conditions. The extent of this potential effect is difficult to quantify, however, for element IVc; construction of a setback levee and breaching a small downstream portion of the existing levee would be expected to create a backwater effect and would not result in a substantial widening of the flood plain. An analysis also was conducted to evaluate the hydraulic effects of the setback levee at element IVc. This hydraulic analysis showed that the proposed action would essentially have no effect on the maximum water surface elevation, with a computed maximum increase in the water surface elevation of 0.0007 feet, and maximum flow rate changes would be negligible during extreme events (100-year flood recurrence interval). Because far afield project-related hydrologic effects are not likely to occur, the action area is concluded to be in the immediate vicinity of the actual project boundaries.

ENVIRONMENTAL BASELINE

HYDROLOGY

SACRAMENTO–SAN JOAQUIN DELTA

The Delta extends inland from the confluence of the Sacramento and San Joaquin rivers west of Antioch to Sacramento on the Sacramento River and to near Mossdale on the San Joaquin River. The Phase 3 Repair Project area is in the southeastern portion of the Delta, within the legal boundary of the Delta as defined by Section 12220 of the California Water Code.

The legal Delta encompasses an area of approximately 851,000 acres (of which approximately 135,000 acres consist of waterway, marshland, or other water surfaces). The Delta is divided into a Primary Zone and a Secondary Zone, as defined by the Delta Protection Act of 1992. Land uses in the Primary Zone are regulated to protect the area for agriculture, wildlife habitat, and recreational uses. The Secondary Zone is the area outside the Primary Zone and within the legal Delta. Where urban development activities occur in the Secondary Zone, efforts should be taken to ensure that these activities do not adversely affect Delta waters, Primary Zone habitat, or recreational uses. The San Joaquin River delineates the boundary between the Primary Zone to the west and the Secondary Zone to the east. The Phase 3 Repair Project is located in the Secondary Zone.

The Sacramento River contributes roughly 75 to 80 percent of the Delta inflow in most years, and the San Joaquin River contributes about 10 to 15 percent; the Mokelumne, Cosumnes, and Calaveras rivers, which flow into the eastern side of the Delta, contribute the remainder. The rivers flow through the Delta and into Suisun Bay, San Pablo Bay, San Francisco Bay, and the Pacific Ocean. Historical annual Delta inflow averaged approximately 23 million acre-feet (MAF) between 1945 and 1995, with a minimum inflow of approximately 6 MAF in 1977 and a maximum of approximately 70 MAF in 1983. Water flowing into the Delta is used for urban and agricultural use, recreation, navigation, and wildlife and fisheries. The Delta provides drinking water for about 23 million Californians.

Freshwater inflows to the Delta vary greatly, depending on precipitation, snowmelt, and Central Valley Project (CVP) and State Water Project (SWP) water operations. During the summer months, most inflow to the Delta comes from regulated releases from SWP and CVP reservoirs. Both projects also withdraw large volumes of water from the Delta for agricultural and urban use. Precipitation in the project region occurs primarily from November through March, with the average annual precipitation ranging from about 8 inches near Tracy to approximately 17 inches near Lodi. Near Lathrop, the annual precipitation is approximately 12 inches.

Water movement in the Delta responds to four primary forcing mechanisms:

- freshwater inflows to the ocean;
- Delta exports and upstream diversions;
- operation of water control facilities such as dams, export pumps, and flow barriers; and
- the regular tidal movement of seawater into and out of the Delta.

In addition, winds and salinity behavior in the Delta can generate secondary currents that, despite being of low velocity, can be of considerable significance with respect to transporting contaminants and mixing different sources of water. Changes in flow patterns in the Delta, whether caused by export pumping, winds, atmospheric pressure, flow barriers, tidal variations, inflows, or local diversions, can influence water quality at drinking water intakes.

The Delta is a hydrologically complex region of interlacing channels, marshland, and islands. The Delta has been reclaimed into more than 60 islands and tracts, interlaced with about 700 miles of waterways. Some channels are edged with aquatic and riparian vegetation, but most are bordered by steep banks of earth or riprapped levees. Vegetation generally is removed from channel margins to increase flood flow capacity and facilitate levee maintenance. About 520,000 acres are devoted to farming. An approximately 1,100-mile network of levees protects the reclaimed land, most of which lies near or below sea level, from flooding. Some of the island interiors are as much as 25 feet below sea level.

Nearly 16.5 miles of the 19 miles of levees protecting RD 17 are considered federal project levees; the 2.6-mile dryland levee is not a federal levee. Federal project levees either were constructed by the federal government (typically through USACE) or were built by others and later brought under federal jurisdiction.

San Joaquin River

The San Joaquin River originates in the Sierra Nevada and enters the San Joaquin Valley at Friant Dam. Most of the flow in the lower San Joaquin River is derived from inflow from the Merced, Tuolumne, and Stanislaus rivers (Northeastern San Joaquin County Groundwater Banking Authority 2004). The 330-mile-long San Joaquin River, which drains a watershed area of 13,540 square miles from the Sierra Nevada to the Delta, contributes approximately 15 percent of the inflow to the Delta (Delta Protection Commission 2000). Flowing through portions of Fresno, Madera, Merced, Stanislaus, San Joaquin, Sacramento, and Contra Costa counties, the river has flows ranging from 1,500 cfs in dry years to more than 40,000 cfs in wet years (Friant Water Users Authority and Natural Resources Defense Council 2002).

Hydrologic conditions in the San Joaquin River basin are dominated by snowmelt from the Sierra Nevada. Before major water storage projects were completed on the San Joaquin River and its major tributaries, lower San Joaquin River flows generally peaked in late spring/early summer and dropped to low levels in the fall. Since completion of Friant Dam (1944), McClure Reservoir (1967 on the Merced River), Don Pedro Reservoir (1971 on the Tuolumne River), and New Melones Reservoir (1979 on the Stanislaus River), the lower San Joaquin River's seasonal flow pattern has changed substantially. Before 1944, based on 1923–1944 records, flow in the lower San Joaquin River tended to peak in May and June, with an average monthly flow of almost 11,000 cfs, and declined rapidly to an average monthly flow of approximately 1,200–1,300 cfs in August and September. Since 1979, the average monthly flow has peaked in March at just over 10,000 cfs, with a more gradual decline to approximately 2,400 cfs in August. In addition, the San Joaquin River is tidally influenced by the Delta and the San Francisco Bay. Tidal fluctuation in the San Joaquin River has been modeled to approximately the Vernalis tide gauge and the Airport Way crossing of the San Joaquin River, which is approximately 13 river miles upstream from the project site.

The SJRRP was established in late 2006, to implement the Stipulation of Settlement in *NRDC et al. v. Kirk Rodgers et al*. (Settlement). Authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act, included in PL 111-11. The goal of the SJRRP is to re-operate and increase the release of water from Friant Dam in accordance with the Settlement, and in a manner consistent with federal, State, and local laws, and future agreements with downstream agencies, entities, and landowners (Reclamation and DWR 2011). The Settlement establishes two primary goals:

- *Restoration Goal*—To restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish. To achieve the Restoration Goal, the Settlement calls for releases of water from Friant Dam to the confluence of the Merced River (referred to as Interim and Restoration Flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon.

- *Water Management Goal*—To reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim and Restoration Flows provided for in the Settlement. To achieve the Water Management Goal, the Settlement calls for recirculation, recapture, reuse, exchange, or transfer of the Interim and Restoration Flows to reduce or avoid impacts on water deliveries to all of the Friant Division long-term contractors caused by the Interim and Restoration Flows.

The SJRRP is to release Interim and Restoration Flows to the San Joaquin River from Friant Dam in accordance with the flow schedule presented in Exhibit B of the Settlement. The Settlement establishes the Recovered Water Account and recovered-water program, which make water available to all Friant Division long-term contractors who provide water to meet Interim or Restoration Flows so that the impacts of Interim and Restoration Flows on such contractors can be reduced or avoided.

LOCAL DRAINAGE

Stormwater runoff in the RD 17 area commonly is collected in agricultural ditches, channels, municipal stormwater sewers, or human-made ponds before being pumped to the San Joaquin River. Runoff from the area east of the San Joaquin River, along levee elements Ie and VIIb, is directed west through agricultural swales and ditches, and then is pumped into the river by means of private agricultural pumps. Runoff from developed lands adjacent to elements IVa, IVc, and VIa.4 is directed to the City of Lathrop's storm drainage system, held in detention basins, and ultimately pumped into the San Joaquin River through a municipal stormwater outfall. Runoff in the area around element VIIe, which encompasses the Oakwood Lake development, first flows into the artificial lake in the center of the development, and then is pumped into the river if lake levels become too high.

WATER QUALITY

Water quality in the Delta and portions of the San Joaquin River are heavily influenced by CVP and SWP operations. Generally, Delta water quality is best during the winter and spring months and poorer during the irrigation season and early fall. Water quality in the San Joaquin River is influenced by factors such as rain and snowmelt runoff, reservoir operations, and irrigation return flows in the San Joaquin river basin. Agricultural return flows commonly discharge elevated salt loads into the San Joaquin River. The SWRCB has set flow and water quality objectives at Vernalis, located just upstream from the Phase 3 Repair Project area. To meet the Vernalis objective, the U.S. Bureau of Reclamation supplements flows on the San Joaquin River with releases from New Melones Reservoir on the Stanislaus River (Northeastern San Joaquin County Groundwater Banking Authority 2004).

The latest version of the Section 303(d) list for California issued by the SWRCB (approved October 26, 2006) identifies an impaired status for waterways in the eastern Delta, including the lower San Joaquin River. Potential sources of pollution for all of the listed constituents in the basin include agriculture, urban runoff/storm sewers, resource extraction, and unknown sources. The eastern Delta, including the lower San Joaquin River, is on the Section 303(d) list for impairment from boron, chlorpyrifos, diazinon, dichlorodiphenyltrichloroethane, electrical conductivity, unknown toxicity, Group A pesticides, exotic species, and mercury. Downstream from the Phase 3 Repair Project area, the Stockton Deep Water Ship Channel is being addressed by a total maximum daily load (TMDL) plan for dissolved oxygen and is no longer on the Section 303(d) list. TMDLs have been initiated for organophosphorus pesticides (i.e., diazinon and chlorpyrifos), salinity and boron, and selenium in the lower San Joaquin River watershed and for total dissolved solids and mercury in Delta channels. TMDLs for the other listed pollutants are scheduled to be developed at various times over the next 10 years, in accordance with the priorities contained in the Section 303(d) list.

Major monitoring programs for the San Joaquin River include DWR's Municipal Water Quality Investigations Program and Water Rights Decision 1485 Water Quality Monitoring Program. The City of Stockton also monitors ambient water quality to assess potential effects of discharges from the Stockton Regional Wastewater Control Facility. Data are collected at five water quality monitoring sites along the San Joaquin River near the Phase 3

Repair Project area. The Mossdale Bridge sampling site at the Interstate 5 crossing over the San Joaquin River is near elements VIcde and VIIb. The Vernalis sampling site is located near the town of Vernalis, just upstream from the Phase 3 Repair Project area. Some of the broad categories that are monitored are discussed briefly below.

HABITAT

Dense riparian forests once flanked the San Joaquin River in this area. In contrast, the habitat today consists of linear areas and occasional remnant patches of riparian forests and related riparian scrub that grow on or adjacent to the levee, primarily on the waterside. A few larger areas of these riparian forests are present where the river turns away from the levee and creates a point bar and an upland floodplain area. Riprap or large boulders cover the lower half of most of the waterside of the San Joaquin River east levee in the Phase 3 Repair Project area, and ruderal vegetation grows in open areas, especially upslope from the riprap and on large open areas on the landside of the levee. Other areas of levee on the waterside are barren and/or covered with stumps and dead vegetation, likely because of levee maintenance that has included cutting scrub and low vegetation, burning, and applying herbicide. Some of the lands on the waterside of the levee are privately held and are affected by grazing and other landowner activities.

The landside reaches of the Phase 3 Repair Project area levees primarily are barren or covered with ruderal vegetation. Beyond the base of the levees, riparian vegetation is rare but occasionally is present in small, isolated patches. Other trees include occasional single or isolated stands of native oaks and nonnative trees that have been planted around farms, agricultural fields, and residential or other types of development. Habitat and land cover types present in the Phase 3 Repair Project area include riparian forests, nonnative woodlands, agricultural lands, ruderal and developed areas, and aquatic features (including marsh, wetlands, and ponds) (**Exhibits 13a** through **13c**).

VEGETATION AND LAND COVER

As described below, terrestrial vegetation and land cover types in the Phase 3 Repair Project area and vicinity include Great Valley cottonwood riparian forest (remnant), Great Valley oak riparian forest (remnant), nonnative woodland, agricultural (row crops, orchards, dirt roads, and irrigation ditches), and ruderal and developed (residential housing, parks, boat launch facilities, and roads).

- **Great Valley cottonwood riparian forest:** Remnant patches of Great Valley cottonwood riparian forest in the Phase 3 Repair Project area are dominated by large Fremont cottonwood (*Populus fremontii*) trees and Goodding's willow (*Salix gooddingii*). Most of the otherwise linear or smaller patchy areas of this community lack Fremont cottonwood and are represented by Goodding's willow, red willow (*S. laevigata*), arroyo willow (*S. lasiolepis*), narrow leaved-willow (*S. exigua*), scattered valley oak (*Quercus lobata*), Oregon ash (*Fraxinus* latifolia), and buttonbush (*Cephalanthus occidentalis*). Native ground cover species, found mainly in the larger remnant patches of riparian forest, include California blackberry (*Rubus ursinus*) and wild rose (*Rosa californica*). Common nonnative understory species found in most elements include Himalayan blackberry (*Rubus discolor*) and tree tobacco (*Nicotina glauca*). Most of the Great Valley cottonwood riparian forest community also could be characterized as Great Valley riparian scrub, which does not include Fremont cottonwood and is characterized by a shorter canopy and more uniform structure. This habitat, however, is part of the Great Valley cottonwood riparian forest that was extensive and connected along this entire reach of the San Joaquin River. Therefore, this BA describes all riparian habitat as such. The largest stands of Fremont cottonwood trees in the Phase 3 Repair Project area are present in elements IIIb, IVc, Va, and VIa.1.
- **Great Valley oak riparian forest:** Great Valley oak riparian forest is located in the Phase 3 Repair Project area, occurring only on the landside of the levees. This is a medium to tall (rarely to 100 feet), broadleaved, winter deciduous, closed-canopy riparian forest dominated by valley oak. Understories include scattered Northern California black walnut (*Juglans nigra*) and western sycamore (*Platanus racemosa*) as well as young valley oaks. Understory plants include California rose (*Rosa californica*), blackberry (*Rubus* spp.), and

western poison oak (*Toxicodendron diversilobum*) (Hickman 1993; Holland 1986). Two substantial oak groves of very large, healthy valley oak trees are present on the landside of elements IIIb and IVa and account for most of the Great Valley oak riparian forest. Several groups of smaller valley oak trees and individual valley oaks, scattered along the landside of other Phase 3 Repair Project elements, also contribute to this community.

- **Nonnative woodland:** Along the landside of elements Ie, VIa.1, VIde, and VIIg, nonnative trees have been planted around farms, agricultural fields, and residential or other types of development. These woodlands lack understory vegetation, other than grasses and ruderal vegetation.

- **Agricultural cropland:** Cropland in the Phase 3 Repair Project area is dominated by alfalfa fields, orchards, and row crops, such as tomatoes. Ruderal species grow along the edges of fields and irrigation ditches, some of which contain water and associated aquatic plants. The largest areas of agricultural lands are present in elements Va, VIa.1, and VIcde.

- **Ruderal vegetation:** Ruderal vegetation is characterized by nonnative weedy and sometimes invasive vegetation and nonnative annual grasses. Common weed species include yellow star-thistle (*Centaurea solstitialis*), black mustard (*Brassica nigra*), shortpod mustard (*Hirschfeldia incana*), Italian thistle (*Carduus pycnocephalus*), milk thistle (*Silybum marianum*), and Himalayan blackberry. Common grass species include ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum* ssp. *leporinum*), Bermuda grass (*Cynodon dactylon*), and Johnsongrass (*Sorghum halepense*). The levee slopes are dominated by ruderal vegetation. Large open areas in elements IIIa and IVc also are composed primarily of ruderal vegetation, as are smaller open areas in elements VIcde and VIIe that border roads, parking lots, and agricultural land.

- **Developed areas:** Developed areas in the Phase 3 Repair Project area consist of residential areas bordering elements IVa, IVc, Va and VIa.1, and VIIe; parks located in elements IVc and VIa.2, the latter of which is also a boat launching facility; and ranch houses and related facilities located in or adjacent to elements Ie, IIab, Va, VIa.1, and dryland levee element XI. Vegetation in residential areas and parks consists of turf grasses, landscape trees, and occasional valley oak trees. Ranch lands often contain English walnut trees (*Juglans regia*), a variety of landscaped trees, and occasional native valley oak trees.

AQUATIC HABITATS

The principal surface water bodies associated with the Phase 3 Repair Project area are the San Joaquin River and Walthall Slough. Project elements Ia through IVc are located downstream from the confluence of the San Joaquin River and Old River. Reach V is located directly adjacent to this confluence. Elements VIa.1 through VIIe are upstream from the confluence of the San Joaquin River and Old River. Small portions of elements VIIe and VIIg are located along Walthall Slough. An approximately 3.5-acre constructed pond is located adjacent to elements IIab, but outside the project footprint (**Exhibit 13a**).

In the Phase 3 Repair Project area, the San Joaquin River is characterized as a wide channel (approximately 300 feet) with little riparian canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. Altered flow regimes, flood risk management, and bank protection efforts along much of the San Joaquin River have reduced riparian vegetation and associated shaded riverine aquatic (SRA) habitat, sediment transport, channel migration and avulsion, and large woody debris recruitment, and have isolated the channel from its floodplain. This has resulted in a decline in habitat quality for fish species using the San Joaquin River near the Phase 3 Repair Project area. However, fish use this segment of the river, even if only as a migratory pathway to and from upstream spawning and rearing areas.

Wetland vegetation in the Phase 3 Repair Project area is limited to coastal and valley freshwater marshes, several agricultural ditches, and the edges of one constructed pond. Freshwater marsh is isolated in a depression on the landside of the levee in element Ib between Howard Road to the north and a dirt farm road on the south. A limited

amount of freshwater marsh also is present around the edges of a constructed pond, located on a large private estate and equestrian center, east of the Phase 3 Repair Project area levee in element IIab. A second area of freshwater marsh is located just outside the Phase 3 Repair Project area in element Va, and in an area of backwater on the San Joaquin River. Agricultural ditches are located along the edges of fields and orchards.

FISH POPULATIONS

The lower San Joaquin River and Delta serve as a migration corridor and/or provide other types of habitat (e.g., rearing, spawning) for steelhead, delta smelt, white sturgeon (*Acipenser transmontanus*), and green sturgeon. Numerous other resident native and nonnative species also are found in the San Joaquin River. Among the native species present in the river are blackfish (*Orthodon microlepidotus*), threespine stickleback (*Gasterosteus aculeatus*), and San Joaquin roach (*Lavinia symmetricus* sp.); while nonnative species include striped bass (*Morone saxatilis*), white catfish (*Ameiurus catus*), and bluegill (*Lepomis macrochirus*). In late 2014, experimental populations of spring-run Chinook salmon began to be reintroduced to the San Joaquin River, as a component of the SJRRP (see "San Joaquin River" subsection above).

The small, unnamed pond in elements IIab (**Exhibit 13a**) may contain fish and other aquatic species. Because of its isolated nature and size, this pond likely supports only nonnative warm-water fish that probably have been introduced. Typical fish that are found in similar ponds include bluegill, western mosquitofish (*Gambusia affinis*), and catfish (*Ameiurus* or *Ictalurus* spp.), among other nonnative warm-water species.

WILDLIFE

Common wildlife species expected in the Phase 3 Repair Project area are those typically associated with agriculture (e.g., alfalfa, row crops, and orchards) and ruderal habitat, which account for 57 percent of the Phase 3 Repair Project area's footprint. Species include California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), western harvest mouse (*Reithrodontomys megalotis*), and California meadow vole (*Microtus californicus*). These small mammals are prey for a variety of raptor species known to occur in the area, including Swainson's hawk (*Buteo swainsoni*). Riparian habitats in the Phase 3 Repair Project area provide nesting habitat for a wide variety of bird species.

SPECIES ACCOUNTS

This section presents species accounts for the federally listed species considered in this BA, including relevant life history and habitat use, as well as the species' potential for occurrence in the action area. The action area (see the "Action Area" section above) encompasses the entire area that may be affected by the Phase 3 Repair Project, including more distant locations where indirect effects may occur. However, the species accounts below focus on the habitat present in the Phase 3 Repair Project area itself and describe the potential for federally listed species to occur in the general vicinity. Only when the habitat quality or species distribution is specifically known for the action area is it described.

VALLEY ELDERBERRY LONGHORN BEETLE

VELB has four life stages: egg, larva, pupa, and adult. This species, which is federally listed as threatened, is nearly always found on or close to its host plant, the elderberry (*Sambucus* sp.). Females lay their eggs on the bark, and larvae hatch and burrow into the stems. The larval stage can last 2 years, after which the larvae enter the pupal stage and transform into adults. Adults are active (feeding and mating) from March to June (USFWS 2006). It appears that to function as VELB habitat, host elderberry shrubs must have stems that are 1.0 inch or greater in diameter at ground level. Use of the plants by the beetle rarely is apparent. Frequently, the only exterior evidence of the shrub's use by the beetle is an oval exit hole, created by the larva just before the pupal stage. Field studies conducted along the Cosumnes River and in the Folsom Lake area suggest that larval galleries can be found in elderberry stems with no evidence of exit holes, because the larvae either succumb before constructing an exit hole or are not far enough along in the developmental process to construct an exit hole (USFWS 1996a).

VELB is patchily distributed throughout the remaining riparian forests of the Central Valley, from Redding to Bakersfield, and appears to be only locally common (i.e., found in population clusters that are not evenly distributed across the Central Valley). Extensive loss of Central Valley riparian forests has occurred since 1900, with riparian forests declining by 80 to 96 percent, depending on the region (USFWS 2006). Although it is wide-ranging, VELB is thought to have suffered a long-term decline because of human activities that have caused widespread alteration and fragmentation of riparian habitats and, to a lesser extent, upland habitats that support the beetle. Low density and limited dispersal capability may cause the beetle to be particularly vulnerable to population isolation because of habitat fragmentation. Insecticide and herbicide use in agricultural areas and along road rights-of-way may be factors limiting the beetle's distribution. The age and quality of individual elderberry shrubs/trees and stands as a food plant for beetle may be a factor in its limited distribution.

Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Repair Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Repair Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat. See **Exhibit 14** for locations of the elderberry shrubs that were observed within 100 feet of the Phase 3 Repair Project area during field surveys in 2014.

CRITICAL HABITAT

Critical habitat for VELB was designated at the time of listing. Two areas along the American River in the Sacramento metropolitan area were designated as critical habitat for this species. The Phase 3 Repair Project area is not located within designated critical habitat for VELB.

RECOVERY PLAN FOR VALLEY ELDERBERRY LONGHORN BEETLE

The Recovery Plan for Valley Elderberry Longhorn Beetle (USFWS 1984) lacks specific goals and does not include objective, measurable recovery criteria (USFWS 2006). The recovery plan identified additional essential habitat for this species in an area along Putah Creek, Solano County, and an area along the American River Parkway, Sacramento County. USFWS released a 5-year status review for VELB on October 2, 2006 (USFWS 2006). This review reported an increase in known beetle locations, from 10 at the time of listing in 1980 to 190 in 2006. Because of the presumed increase in the estimated population and the concurrent protection and restoration of several thousand acres of riparian habitat suitable for VELB, USFWS's status review determined that this species is no longer in danger of extinction and recommended that the species no longer be listed under the ESA. On October 2, 2012, the USFWS issued a proposed rule to delist VELB (78 FR 66058); however, on September 17, 2014, the USFWS withdrew this proposal, stating that the scientific information and analysis reflected in the October 2012 proposal was not strong enough to support a decision to delist the species (79 FR 55874).

RIPARIAN BRUSH RABBIT

Riparian brush rabbit, which is federally listed as endangered, inhabits riparian communities in the northern San Joaquin Valley that are dominated by thickets of willows and large clumps of shrubs and vines, such as wild rose, blackberries, coyote bush, and wild grape. Historically, riparian brush rabbit inhabited dense, brushy areas of valley riparian forests, marked by extensive thickets of wild rose, blackberries, and willows (Sandoval et al. 2006).

Suitable habitat for riparian brush rabbit is characterized by an abundance of woody ground litter, mats of low-growing vines and shrubs, and areas of higher ground not subject to regular or heavy flooding (Sandoval et al. 2006). On a seasonal basis, it also may use dense, tall stands of herbaceous plants adjacent to patches of riparian shrubs (Williams and Hamilton 2002). It tends to avoid large openings in the understory cover, frequenting only small clearings in the vegetation while foraging (USFWS 1998). An essential component of habitat for riparian brush rabbit is high-ground refugia from flooding, which provides protection from predators and dry habitat during prolonged rainstorms (USFWS 1998).

The only known populations of riparian brush rabbit are confined to Caswell Memorial State Park on the Stanislaus River in Stanislaus County, approximately 10 miles southeast of the Phase 3 Repair Project area, and in the South Delta along the San Joaquin River and overflow channels (Williams and Hamilton 2002; Williams et al. 2002; Lloyd and Williams 2003; Vincent-Williams et al. 2004; CDFW 2014) (**Exhibit 15**). The population in the South Delta is found in Paradise Cut along the rights-of-way of the two railroads that cross Paradise Cut and Tom Paine Slough, and in an oxbow on the San Joaquin River near Mossdale Landing (CDFW 2014). Riparian brush rabbits also have been found along the San Joaquin River north of the oxbow population, in waterside riparian habitat near the Phase 3 Repair Project area adjacent to elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1, and VIa.4 (CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004) (**Exhibit 15**). Other historical habitats along the San Joaquin River and tributaries are believed to no longer be suitable for riparian brush rabbits because of irrigated agriculture, livestock grazing, and impoundment and channelization of streams. High-ground refugia also may be lacking in these areas (Williams and Hamilton 2002).

In Paradise Cut, existing habitat for riparian brush rabbits is confined to levee bases, the channel banks of Paradise Cut, and pockets of low ground along the bottom of Paradise Cut. Generally, areas of suitable habitat in these locations are very narrow (15 to 100 feet wide). Most of the channels in Paradise Cut are in effect dead-end sloughs fed by Old River, with large portions containing water year-round, which results in the isolation of some upland areas (i.e., islands). The existing habitat for rabbits is covered in water on average once every 4 years, when flood flows in the San Joaquin River are sufficient to overtop Paradise Weir. Brush rabbits probably use the UPRR right-of-way as high-ground refugia during flooding events (Williams and Hamilton 2002).

Occupied habitat for riparian brush rabbit is documented adjacent to the Phase 3 Repair Project area along the waterside levee in elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1, and VIa.4. The waterside habitat along elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The waterside habitat between elements IIab and IIIa is dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The waterside habitat between elements VIa.1 and VIa.4 is on an oxbow with dense riparian vegetation. Other patches of riparian vegetation along the San Joaquin River and adjacent to Phase 3 Repair Project area levees, such as the Great Valley cottonwood forest and Great Valley oak riparian forest communities shown in **Exhibits 13a** through **13c**, provide potentially suitable habitat for riparian brush rabbit, including the small areas of riparian habitat that are present on the waterside of Phase 3 Repair Project area elements IIab, IVc, and Va.

Riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover rather than in large openings. It feeds on herbaceous vegetation, such as grasses, sedges, clover, forbs, and buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). This species has a small home range and mainly remains hidden under protective shrub cover, seldom venturing more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.

CRITICAL HABITAT

Critical habitat has not been designated for riparian brush rabbit.

RECOVERY PLAN FOR RIPARIAN BRUSH RABBIT

The Recovery Plan for Upland Species of the San Joaquin Valley, California addresses the riparian brush rabbit (USFWS 1998). At the time the recovery plan was prepared, only the Caswell Memorial State Park population was known to exist. One of the most important conservation actions identified in the plan was establishment of other viable populations within the park’s range. The recovery plan recommended the following actions (USFWS 1998):

- Initiate a reintroduction program that includes researching genetic diversity among remaining individuals.
- Implement a captive breeding program to translocate individuals to new populations.
- Establish at least three additional wild populations in the San Joaquin Valley in restored and expanded suitable habitat within the rabbit’s historical range.

In 1999, the Endangered Species Recovery Program began implementing the Controlled Propagation and Reintroduction Plan for the Riparian Brush Rabbit (Williams et al. 2002), which was recommended in the Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998). The primary goal of the program is to prevent extinction by providing animals for reintroduction to establish new populations or augment existing populations. In July 2002, captive-bred rabbits were released at the San Luis National Wildlife Refuge, near Los Banos in the central San Joaquin Valley, and in 2005, a population of captive-bred rabbits was introduced to a private ranch along the San Joaquin River in Stanislaus County, adjacent to the San Joaquin River National Wildlife Refuge (USFWS 2007). This effort is ongoing.

DELTA SMELT

Delta smelt was formally listed as threatened under the ESA on March 5, 1993 (59 FR 440). On December 19, 1994 (59 FR 65256), USWFS designated critical habitat. Delta smelt is found only from Suisun Bay upstream through the Sacramento–San Joaquin estuary in Contra Costa, Sacramento, San Joaquin, Solano, and Yolo counties.

Delta smelt is endemic to the upper Sacramento–San Joaquin River estuary and occurs primarily in open surface waters of Suisun Bay, in the Sacramento River downstream from Isleton, and in the San Joaquin River downstream from Mossdale (Bennett 2005), including the project area. Its historic range is thought to have extended from Suisun Bay upstream to at least the city of Sacramento on the Sacramento River and Mossdale on the San Joaquin River. Delta smelt historically was one of the most common pelagic fish (fish living in open water away from the bottom) in the upper Sacramento–San Joaquin estuary (USFWS 2004). The delta smelt population generally is concentrated in the estuary west of the confluence of the Sacramento and San Joaquin rivers in high-outflow years and in the north Delta in low-outflow years (Sweetnam 1997, 1998; Bennett 2005). Delta outflow determines the location of the salinity gradient and may strongly influence delta smelt distribution. USFWS data indicate that delta smelt is found in the San Francisco Bay/Sacramento–San Joaquin Delta (Bay-Delta) estuary where salinity generally is less than two parts per thousand. Except when spawning in freshwater, delta smelt most frequently is caught in or is slightly upstream from the entrapment zone (Bennett 2005). In the CDFW Delta-wide 20mm delta smelt survey, delta smelt larvae were observed only occasionally and in very low abundance in the vicinity of the project area (less than four larvae in 10,000 cubic meters as sampled on April 4, 2014). The species was not observed in the project vicinity in 2015 or 2016, during the delta smelt monitoring program that occurs from January through March.

CRITICAL HABITAT

Although the Phase 3 Repair Project area is near the upper limit of the known distribution of delta smelt, it is included in the area designated as critical habitat for the species (Critical Habitat Determination for the Delta Smelt, 59 FR 65256, December 19, 1994). In the critical-habitat designation, USFWS identified the following primary constituent elements essential to conservation of delta smelt: physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration (59 FR 65256). The primary constituent elements are organized by habitat conditions required for each life stage. USFWS has identified specific areas in the Delta for spawning habitat, larval and juvenile transport, and adult migration for delta smelt. The Phase 3 Repair Project area and larger action area include places identified for larval and juvenile transport and adult migration, but do not include specific areas important for delta smelt spawning habitat (59 FR 65256).

RECOVERY PLAN FOR DELTA SMELT

The Sacramento–San Joaquin Delta Native Fishes Recovery Plan includes restoration of abundance and distribution of delta smelt (USFWS 1996b). Action items in the recovery plan for delta smelt refer to four zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of delta smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Repair Project area or action area.

LONGFIN SMELT

On April 2, 2012, the USFWS issued its finding that the longfin smelt warranted protection under the ESA, and added it as a candidate species for protection under the ESA (77 FR 19755). Longfin smelt is found in bay, estuarine, and nearshore coastal environments from San Francisco Bay north to Lake Earl near the Oregon border. The southernmost detection of the species was a single fish from Monterey Bay (Eschmeyer et al. 1983), although

spawning has not been documented south of San Francisco Bay. The San Francisco estuary and the Delta support the largest longfin smelt population in California. Longfin smelt is more broadly distributed throughout the Bay-Delta estuary and is found in water with higher salinities than delta smelt. Longfin smelt most often is concentrated in Suisun Bay, San Pablo Bay, and northern San Francisco Bay during nonspawning periods (Moyle 2002). No fish surveys have been conducted by RD 17 within the river stretch adjacent to the Phase 3 Repair Project area; however, CDFW's Delta-wide sampling program, including the 20mm delta smelt survey, longfin smelt larva survey, summer tow net survey, and spring Kodiak Trawl sampling, occurs in the vicinity of this area. Longfin smelt has a short life span, generally reaching maturity at 2 years of age, when it spawns and then dies. During the second year of life, adults tend to inhabit the higher salinity western portion of the estuary system; they occasionally have been found in nearshore ocean surveys (Rosenfield and Baxter 2007). Adults spend their lives in bays, estuaries, and nearshore coastal areas, and migrate into low-salinity or freshwater reaches of coastal rivers and tributary streams to spawn. Spawning occurs in the lower portions of the Sacramento and San Joaquin rivers and adjacent sloughs, typically between November and June, with peak spawning occurring from February through April (Baxter 1999; DWR 2009; Moyle 2002; Wang 1986). On the San Joaquin River, spawning occurs downstream from Medford Island, approximately 20 miles downstream from the project site (Moyle 2002). Locations and movements of all life stages of longfin smelt are influenced by a wide range of hydrologic and environmental variables (Rosenfield 2010), all of which show high variation among and within years; accordingly, temporal and spatial distributions of longfin smelt show high variation among and within years.

CRITICAL HABITAT

Because the longfin smelt has not been listed, no critical habitat has been designated.

RECOVERY PLAN FOR LONGFIN SMELT

The Sacramento–San Joaquin Delta Native Fishes Recovery Plan includes restoration of abundance and distribution of longfin smelt (USFWS 1996b). Action items in the recovery plan for longfin smelt refer to five zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of longfin smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Repair Project area or action area.

CENTRAL VALLEY STEELHEAD DISTINCT POPULATION SEGMENT

On March 19, 1998, NMFS listed the Central Valley steelhead DPS as threatened (63 FR 13347). Central Valley steelhead DPS is considered to be winter-run steelhead (McEwan and Jackson 1996). In the most recent 5-year review of the listing of this species, NMFS recommended that the Central Valley steelhead DPS should remain classified as a threatened species (NMFS 2011a). Findings of the next 5-year status review for all federally listed anadromous salmonids in the Central Valley are anticipated to be published in 2016. Like other anadromous salmonid species, this one matures in the ocean before entering freshwater on its spawning migrations. The major factor influencing steelhead populations in the San Joaquin River system is loss of habitat caused by construction of impassable dams on the mainstem and major tributaries.

Historically, Central Valley steelhead was found throughout the Sacramento and San Joaquin drainages, where waterways were accessible to migrating fish. Steelhead historically was present in the upper San Joaquin River basin, upstream from the current location of Friant Dam. Steelhead commonly migrated far up tributaries and into headwater streams where cool, well-oxygenated waters were present year-round.

Currently, in the Central Valley, viable populations of naturally produced steelhead are found only in the Sacramento River and its tributaries. Wild steelhead populations appear to be restricted to tributaries of the Sacramento River below Keswick Dam, such as Antelope, Deer, and Mill Creeks, and to the Yuba River below Englebright Dam (McEwan and Jackson 1996). No significant populations of steelhead remain in the San Joaquin

River basin; however, small persistent runs still occur on the Stanislaus and Tuolumne rivers, and perhaps the Merced River (McEwan and Jackson 1996).

Juvenile steelhead rear throughout the year and may spend 1 to 3 years in freshwater before emigrating to the ocean. Smoltification, the physiological adaptation that juvenile salmonids undergo to tolerate saline waters, occurs in juveniles as they begin their downstream migration. Smolting steelhead (age class 1+ and older) generally emigrate from March to June (Barnhart 1986; Reynolds et al. 1993).

The San Joaquin River near the Phase 3 Repair Project area is used by adult and juvenile steelhead primarily as a migration corridor between the ocean and cold-water habitat in the upstream tributaries. Juvenile steelhead would be likely to use the edges of rivers and sloughs, and floodplain habitats, if available, for rearing as they emigrate (Moyle 2002).

Critical Habitat

Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins. The Phase 3 Repair Project area is located within designated critical habitat for the Central Valley steelhead DPS.

Recovery Plan for Central Valley Steelhead Distinct Population Segment

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Although habitat conditions for Central Valley steelhead have improved slightly over the past decade, access to historic habitat generally remains blocked, and the quality of the species' remaining habitat generally remains degraded (Lindley et al. 2009; Cummins et al. 2008).

CENTRAL VALLEY FALL/LATE FALL-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

On September 16, 1999 (64 FR 50393), NMFS determined that listing was not warranted for the Central Valley fall/late fall–run Chinook salmon ESU; however, the ESU was designated as a future candidate for listing because of concerns about specific risk factors. On April 14, 2004 (69 FR 19975), the ESU was reclassified as a species of concern. The ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin River basins and their tributaries, east of the Carquinez Strait. The Central Valley fall/late fall–run Chinook salmon ESU currently is the only run of Chinook salmon in the San Joaquin River system.

Adult Central Valley fall/late fall–run Chinook salmon enter the Sacramento and San Joaquin river systems from September through January and spawn from October through February. In general, San Joaquin River populations tend to mature at an earlier age and spawn later in the year than Sacramento River populations (Baker and Morhardt 2001). These differences may be phenotypic responses to the generally warmer temperature and lower flow conditions found in the San Joaquin River basin, relative to the Sacramento River basin.

Juveniles typically rear in freshwater for 3 to 6 months (fall-run) and up to 12 months (late fall–run) before entering the ocean. Juveniles migrate downstream from January through June. Juvenile Chinook salmon prefer water depths of 0.5 foot to 3.3 feet and velocities of 0.26 foot to 1.64 feet per second (Raleigh et al. 1986). Important winter habitat for juvenile Chinook salmon includes flooded bars, side channels, and overbank areas with relatively low water velocities. Juvenile Chinook salmon have been found to rear successfully in floodplain habitat, which routinely floods but is dry at other times. Growth rates appear to be enhanced by the conditions found in floodplain habitat (Sommer et al. 2001).

Cover structures, space, and food are necessary components for Chinook salmon rearing habitat. Suitable habitat includes areas with instream and overhead cover in the form of undercut banks, downed trees, and large, overhanging tree branches. The organic materials forming fish cover also help provide sources of food, in the form of both aquatic and terrestrial insects.

Fall-run Chinook salmon adults primarily pass through the Phase 3 Repair Project area on their way to spawn in upstream tributaries of the San Joaquin River (Moyle 2002). Juvenile fall-run Chinook salmon emigrate from San Joaquin River tributaries (e.g., the Stanislaus, Merced, and Tuolumne rivers) and other river tributaries through the San Joaquin River during the late winter and spring (February through mid-June) (San Joaquin River Group Authority 2009). Juvenile Chinook salmon use the edges of rivers and sloughs for rearing as they emigrate downstream (Moyle 2002).

CRITICAL HABITAT

No critical habitat has been designated for Central Valley fall/late fall-run Chinook salmon.

ESSENTIAL FISH HABITAT

EFH has been designated for Pacific Salmon. This includes identification of Chinook salmon EFH, which occurs in the project and action areas. Central Valley fall/late fall-run Chinook salmon ESU is in the Phase 3 Repair Project area along the San Joaquin River. EFH includes migration, holding, and rearing habitat and opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014a).

Construction of element IVc would improve EFH, by providing the type of refuge habitat for juvenile salmonids during high-water flows as described in Amendment 18 for the lower San Joaquin River tributaries (NMFS 2014c).

RECOVERY PLAN FOR CENTRAL VALLEY FALL/LATE FALL–RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

Although the Central Valley fall/late fall-run Chinook salmon is not listed as threatened or endangered under the ESA, the Sacramento–San Joaquin Delta Native Fishes Recovery Plan outlines conservation measures and restoration objectives and criteria for the species, including the San Joaquin River run, which CDFW recognizes as a distinct stock (USFWS 1996b). Reasons for decline identified by the plan include habitat loss, suitability of habitat, survival of outmigrants, harvest, hatcheries, and water quality. Conservation measures include:

- testing an electrical fish barrier and a physical barrier upstream from the confluence of the Merced River to prevent adult fish from straying,
- constructing and rehabilitating spawning riffles,
- constructing a temporary barrier at Old River to prevent entrainment of outmigrating smolts, and when possible,
- coordinating water releases to provide attraction or outmigration flows.

These efforts have been funded by a wide range of federal, State, and private agencies (USFWS 1996b).

SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

The Sacramento River winter-run Chinook salmon was formally listed as threatened in November 1990 (55 FR 46515), and was reclassified as endangered under the ESA on January 4, 1994 (59 FR 440).

In the Delta, winter-run adults begin to move through the system in early winter (November–December), with the first upstream adult migrants appearing in the upper Sacramento River during late December (Vogel and Marine 1991, cited in NMFS 2003). Adult winter-run presence in the upper Sacramento River system peaks in March. The timing of migration may vary somewhat because of changes in river flows, dam operations, and water year type. Spawning occurs primarily from mid-April to mid-August, with peak activity occurring in May and June in the river reach between Keswick Dam and the Red Bluff Diversion Dam (Vogel and Marine 1991, cited in NMFS 2003).

Juvenile winter-run Chinook salmon occur in the Delta from October through early May, based on data collected from trawls, beach seines, and salvage records at State and federal water projects (DFG 1998). The peak of juvenile arrivals is between January and March. Juveniles tend to rear in the freshwater upper Delta areas for about the first 2 months (Kjelson et al. 1981, 1982). As they mature, winter-run Chinook fry and fingerlings prefer to rear farther downstream, where ambient salinity is up to 1.5 to 2.5 parts per thousand (Healey 1980, 1982; Levings et al. 1986). Fry remain in the estuary until they reach a fork length of about 118 millimeters (i.e., at 5 to 10 months of age). Emigration from the Delta may begin as early as November and continue through May (Fisher 1994; Myers et al. 1998).

With the exception of occasional strays, adult winter-run Chinook salmon generally do not occur in the San Joaquin River or in this portion of the Delta, and therefore, do not occur in the action area. The same is true for juvenile winter-run Chinook salmon.

CRITICAL HABITAT

Critical habitat for the winter-run Chinook salmon ESU was designated by NMFS on June 16, 1993 (58 FR 33212), with an effective date of July 16, 1993. Critical habitat is designated to include the Sacramento River from Keswick Dam (River Mile 302) to Chipps Island (River Mile 0) and all waters westward, including San Francisco Bay north of the Bay Bridge to the Golden Gate Bridge. The proposed action is not within designated critical habitat.

ESSENTIAL FISH HABITAT

EFH for Chinook salmon, which includes Sacramento River winter-run Chinook salmon ESU (NMFS 2014a), has been identified in the project and action areas.   See the section on Central Valley fall/late fall-run Chinook salmon, Essential Fish Habitat.

RECOVERY PLAN FOR SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. In essence, improvement in the status of winter-run Chinook salmon ESU depends on re-establishment of an alternate population in a historically used area (e.g., Battle Creek) (Williams et al. 2011). Improvement of spring-run Chinook salmon ESU is dependent on improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects also are of primary importance in improving the status of this ESU (NMFS 2014b).

Recovery goals and restoration actions for Sacramento River winter-run Chinook salmon ESU are described by Williams et al. (2011) for the Sacramento River basin, including re-establishment of a population in a historically used area (e.g., Battle Creek) and fish passage improvement projects. Recovery goals do not, however, apply to the action area, because reintroduction of winter-run Chinook salmon is not planned for the San Joaquin River Basin.

CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

NMFS listed Central Valley spring-run Chinook salmon as threatened on September 16, 1999 (50 FR 50394).

Central Valley spring-run Chinook salmon historically was the most abundant run of Central Valley Chinook salmon (Fisher 1994). It occupied the headwaters of all major river systems in the Central Valley, where no natural barriers existed. Adults returning to spawn ascended the tributaries to the upper Sacramento River, including the Pit, McCloud, and Little Sacramento rivers. They also occupied Cottonwood, Battle, Antelope, Mill, Deer, Stony, Big Chico, and Butte creeks and the Feather, Yuba, American, Mokelumne, Stanislaus, Tuolumne, Merced, San Joaquin, and Kings rivers. Spring-run Chinook salmon migrated farther into headwater streams, where cool, well-oxygenated water was available year-round.

Surveys indicate that populations of remnant, non-sustaining spring-run Chinook salmon may be found in Cottonwood, Battle, Antelope, and Big Chico creeks (DWR 1997); more sizable, consistent runs of naturally produced fish are found only in Mill, Deer, and Butte creeks (Williams et al. 2011). All these creeks are tributaries in the Sacramento River basin. The Feather River Fish Hatchery sustains the spring-run population on the Feather River, but the genetic integrity of that run is questionable (DWR 1997). Although all of these populations are found in the Sacramento River basin, the ESU boundary of Central Valley spring-run Chinook salmon includes populations spawning in the Sacramento River and San Joaquin River basins, as reflected in the current 5-year status review (Williams et al. 2011; NMFS 2011b). The status of Central Valley spring-run Chinook salmon ESU likely has not improved since the 2005 status review (Williams et al. 2011). Improvement of spring-run Chinook salmon ESU is dependent on improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects also are of primary importance in improving the status of this ESU (NMFS 2014a). Current and future efforts to restore production in the San Joaquin River are either being planned or are just beginning, and no results about their current efficacy are available.

Like winter-run Chinook salmon, adult spring-run Chinook salmon (other than occasional strays) generally have not occurred in the San Joaquin River basin, and therefore, do not occur in the action area. The same is true for juvenile spring-run Chinook salmon.

CRITICAL HABITAT

Critical habitat for the Central Valley spring-run Chinook salmon was designated on August 12, 2005; a final designation was published on September 2, 2005, with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include selected waters in the Sacramento River basin from approximately Redding (River Mile 302) to approximately Chipps Island (River Mile 0) at the westward margin of the Delta and includes the Sacramento River. The Phase 3 Repair Project area is located outside the species' designated critical habitat.

ESSENTIAL FISH HABITAT

EFH for Chinook salmon, which includes Central Valley spring-run Chinook salmon ESU (NMFS 2014a), has been identified in the project and action areas. See the section on Central Valley fall/late fall-run Chinook salmon, Essential Fish Habitat.

RECOVERY PLAN FOR CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Recovery goals and restoration actions are outlined for the Sacramento River basin and do not apply to the action area.

As discussed above in the "San Joaquin River" subsection of the "Environmental Baseline" section, one of the goals of the SJRRP is "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish" (Reclamation and DWR 2011). The Settlement stipulates reintroduction of spring-run and fall-run Chinook salmon, with a priority given to restoring self-sustaining populations of wild spring-run Chinook salmon.

NORTH AMERICAN GREEN STURGEON DISTINCT POPULATION SEGMENT

On April 7, 2006, NMFS listed the Southern DPS of the North American green sturgeon as threatened under the ESA. In North America, green sturgeon is found from Ensenada, Mexico to southeast Alaska. The Southern DPS includes individual reproductive populations south of the Eel River. The populations north of the Eel River, grouped as the Northern DPS, currently do not warrant listing.

Green sturgeon is found in the lower reaches of large rivers, including the Sacramento–San Joaquin River basin, and in the Eel, Mad, Klamath, and Smith rivers. Green sturgeon adults and juveniles are found throughout the upper Sacramento River, as indicated by observations incidental to winter-run Chinook monitoring at Red Bluff Diversion Dam in Tehama County (Poytress et al. 2013; NMFS 2005). Green sturgeon spawns predominantly in the upper Sacramento River and is found primarily in the mainstem Sacramento River.

The green sturgeon is a primitive, bottom-dwelling fish, characterized by its large size (up to 7 feet long and 350 pounds), with a long, round body and "scutes" or plates along its dorsal and lateral sides. It is known to migrate up to 600 miles between freshwater and salt water environments and commercially is caught in the Columbia River and coastal Washington (PFMC 2003). Like all sturgeon species, it is anadromous, but it also is the most marine-oriented of the sturgeon species (NMFS 2005). It spends most of its life in salt water and returns to spawn in freshwater. Individuals congregate in the bays of these systems in summer, while some may travel upstream to spawn in spring and summer. Adult Southern DPS green sturgeon enter San Francisco Bay in late winter through early spring and spawn from April through early July, depending on water flow and temperature (Heublein et al. 2009).

The Southern DPS of the North American green sturgeon is slow growing and late maturing, reaching sexual maturity at about 15 years, at a length of about 5 feet, and typically spawning every 3 to 4 years (NMFS 2015). Green sturgeon spawning has been documented only in the Klamath, Sacramento, and Rogue rivers during recent times (NMFS 2005), although a spawning event was documented in 2011 in the lower Feather River at the Thermalito Afterbay Outlet (Seesholtz et al. 2014). Green sturgeon spawning in the San Joaquin River is not documented, as reported in the 5-year species status review for the Southern DPS of the North American green sturgeon (NMFS 2015).

Green sturgeon populations in the Southern DPS have relatively small population sizes, potentially have lethal temperature limits, face entrainment by water projects and influences of toxic material and exotic species, and may be susceptible to catastrophic events. Impassable barriers to spawning grounds are an additional threat. Preliminary Southern DPS population size estimates are being provided from Dual Frequency Identification Sonar surveys of aggregating sites in the upper Sacramento River; surveys conducted between 2010 and 2014 indicated an annual range of 164 to 526 spawning adults (personal communication with Ethan Mora, UC Davis, March 30, 2015, reported in NMFS 2015). Based on an estimate of mean spawning periodicity, as many as 1,348 ± 524 adults are estimated in the Southern DPS (personal communication with Ethan Mora, UC Davis, May 6, 2015, reported in NMFS 2015).

Green sturgeon may occur in the San Joaquin River between Stockton and the Highway 140 bridge (IEP 2013), including in the Phase 3 Repair Project area, although no evidence exists of historical use of the San Joaquin River by green sturgeon (BRT 2005; Beamesderfer et al. 2007). No documentation is known for green sturgeon spawning in the San Joaquin River, but spawning may have occurred before construction of large-scale hydropower and irrigation development (Mora et al. 2009). White sturgeon persist in the San Joaquin River at population levels of 10 percent of Sacramento River population levels. Young green sturgeon have been taken occasionally in the Santa Clara Shoal area in the Delta, but these fish likely originated in the Sacramento River (NMFS 2005).

CRITICAL HABITAT

Critical habitat for Southern DPS of North American green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

RECOVERY PLAN FOR NORTH AMERICAN GREEN STURGEON DISTINCT POPULATION SEGMENT

A recovery plan has not been developed for green sturgeon, but the Federal Recovery Outline for the Southern DPS of the North American green sturgeon is available (NMFS 2010).

DIRECT AND INDIRECT EFFECTS ON SPECIES IN THE ACTION AREA

Under the ESA, direct effects are those that are caused by the project and occur at the same time as the action (e.g., construction-related effects). Indirect effects are those that are caused by the proposed action and are later in time but are reasonably certain to occur and there is a causal relationship with the action (e.g., operational effects). In other words, there is a logical, unbroken, traceable, explainable, predictable, chain of effects that result in, or "cause" a given effect on listed species. Avoidance and minimization measures for both direct and indirect effects are presented in the "Avoidance and Minimization Measures" section above.

VALLEY ELDERBERRY LONGHORN BEETLE

No known documented occurrences exist of VELB in the Phase 3 Repair Project area, but the species could use elderberry shrubs in the action area. Elderberry shrubs that could support beetles are sparsely scattered throughout the action area, along both the waterside and landside of the San Joaquin River levee.

Eighteen elderberry shrubs are present in or adjacent to the footprint of the Phase 3 Repair Project. The nine elderberry shrubs located along the waterside of the Phase 3 Repair Project levees would be avoided and protected during construction (see "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle"). The nine elderberry shrubs located along the landside of the levee would require removal to accommodate construction of the Phase 3 Repair Project's seepage berms, cutoff walls, and setback levee (**Table 5**; **Exhibit 14**). However, one of these landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

Table 5
Survey Results for Landside Elderberry Shrubs to be Removed from the Phase 3 Repair Project Area

Shrub Number	Number of Stems per Diameter Category (inches)			Beetle Exit Holes Present?	Riparian?
	≥ 1 and ≤ 3	≥ 3 and ≤ 5	≥ 5		
9	0	0	0	No	No
10	73	6	0	No	No
11	25	17	8	No	No
13	12	4	4	No	No
14	5	4	2	No	No
15	32	11	2	No	No
16	13	4	1	No	No
17	25	4	5	No	No
18	6	5	0	No	No
Total	**191**	**55**	**22**		

Notes:
Riparian = waterside of levee; Nonriparian = landside of levee
Source: Data compiled by AECOM in 2014

The eight elderberry shrubs on the landside have a total of 268 stems that are greater than 1 inch in diameter at ground level. These shrubs would require removal during construction of the Phase 3 Repair Project, resulting in direct effects on VELB. If the stems are occupied by beetles, any early-stage individuals are likely to be killed when the shrub is removed. Complete loss of the shrubs to be removed should be avoided by transplanting during the shrubs' dormant season; however, transplanted elderberry shrubs can experience stress or health problems because of changes in soil, hydrology, microclimate, or associated vegetation, and mortality of transplanted shrubs would preclude their future use by the beetle. Removing shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected; alternately, adverse effects on elderberry shrubs could have an overall effect on the beetle, even if larvae are absent at the time of impact, if the shrubs are relied on for reproduction. In addition, it takes 5 or more years for replacement elderberry plantings to reach a size conducive to use as VELB habitat. Therefore, a temporary loss of habitat available to the beetle would occur. The Phase 3 Repair Project would comply with avoidance and minimization measures described for VELB and would compensate for removal of these stems, in accordance with the VELB Guidelines (USFWS 1999). A net reduction in the number of elderberry shrubs would be avoided by requiring establishment of 367 elderberry seedlings and 367 associated native plantings.

Elderberry shrubs that cannot be avoided would be transplanted to the levee setback area in element IVc (**Exhibit 12**). The restoration design, as outlined in the Conceptual MMP (**Appendix E**), would include 367 elderberry seedlings and 367 associated species plantings to compensate for the effects to VELB habitat in the Phase 3 Repair Project area.

After construction of the Phase 3 Repair Project, RD 17 would continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which would include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). Trees only would be trimmed, not removed, under these practices. Therefore, no change would occur in the number of elderberry shrubs along the RD 17 levees.

RIPARIAN BRUSH RABBIT

As shown in **Table 6**, the Phase 3 Repair Project levee improvements would result in the removal of 3.28 acres of landside riparian habitat—specifically Great Valley cottonwood riparian forest and Great Valley oak riparian forest—that is suitable for riparian brush rabbit. This riparian habitat is located on the landside of the levee, where levee improvements (e.g., chimney drains, seepage berms) would be constructed. In general, most of the landside riparian vegetation is sparse and lacks understory vegetation other than grasses and ruderal vegetation, which would act as cover for riparian brush rabbit and would not be suitable for this species (Hansen, pers. comm., 2011). However, potential exists for some of these landside woody habitats to support suitable habitat for riparian brush rabbit, particularly because they are located adjacent to waterside riparian habitats that either are known to be occupied by this species or are highly suitable habitat. All landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied or highly suitable for riparian brush rabbit (i.e., elements IIab through element VIe). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species. No waterside woody or riparian habitat would be removed because of levee improvement activities.

Nearly 54 acres of ruderal annual grassland also would be affected by Phase 3 Repair Project implementation. All effects on ruderal annual grassland that would result from levee improvements are assumed to be temporary because annual grassland would be reestablished in these areas after project completion. Although riparian brush rabbit may use annual grassland as a source for foraging habitat, the key component of habitat suitability for this species in the Phase 3 Repair Project area is based on the presence of riparian woody vegetation and not the surrounding grasslands. Riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover, rather than in large openings, feeding on herbaceous vegetation, such as grasses, sedges, clover, forbs, buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). Furthermore, because this species is known to have a small home range and seldom ventures more than 1 meter (3.3 feet) from cover

(Sandoval et al. 2006), the riparian brush rabbit likely uses only a small component of the grassland, and its use of such habitat is concentrated along the edges of the riparian areas.

Table 6
Effects of Implementing the Phase 3 Repair Project on Suitable Riparian Brush Rabbit Habitats

	Acres of Directly Affected Suitable Habitat
Waterside woodlands[1]	0.00
Landside woodlands[1,2]	3.28
Total	**3.28**

Notes:
[1] Suitable riparian brush rabbit habitats are characterized as Great Valley cottonwood riparian forest and Great Valley oak riparian forest.
[2] Most of the landside riparian vegetation is sparse and lacks understory and is not suitable for this species (Hansen, pers. comm., 2011). However, any landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied by or highly suitable for riparian brush rabbit (i.e., elements IIab through elements Vie). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.
Source: Data compiled by AECOM in 2014

RD 17's ongoing practice for vegetation encroachment management is limited to trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up 5 feet above the ground or 12 feet above the crown road. Thus, trees and shrubs are only trimmed, not removed, because of this maintenance practice. Thus, RD 17's long-term management of vegetation encroachments on the landside and waterside of the levee is not expected to result in reduction or change to existing riparian habitat. The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed because of Phase 3 Repair Project construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed because of Phase 3 Repair Project construction (3.28 acres; see **Table 6**), but none would be removed because of future vegetation management activities.

The loss of potential riparian brush rabbit habitat in the Phase 3 Repair Project area could restrict the range of this species because the RD 17 area currently contains the northernmost known extent of the population on the San Joaquin River. It also could isolate other populations residing in residual habitats in the project vicinity. However, the proposed conservation measures (see the "Avoidance and Minimization Measures" and "Compensation Measures" sections above) would minimize direct loss of riparian habitat in conjunction with compensation for adverse effects. Implementing such measures is anticipated to avoid a net reduction in the number of riparian brush rabbit and its associated habitat. The Phase 3 Repair Project would include restoration of at least 9.9 acres of riparian scrub habitat and upland refugia in the setback area at element IVc (**Exhibit 12**). The expansion and restoration of riparian habitat in element IVc would augment the waterside riparian corridor along the San Joaquin River and would provide additional riparian habitat opportunities for the riparian brush rabbit between two known occurrences of this species (i.e., between elements IIIa/IIIb and elements VIa.1/VIa.4 [CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). The restored riparian scrub habitat (up to 7.5 acres) would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee would remain in place, and up to 4 acres of Great Valley oak woodland would be established on it, thus providing upland refugia for the riparian brush rabbit during high-water events. The restoration of approximately 9.9 acres (and up to 11.5 acres) of suitable habitat for riparian brush rabbit would achieve a 3:1 restoration to impact mitigation ratio (for effect on potential riparian brush rabbit habitat).

FEDERALLY LISTED FISH SPECIES

Fish species/ESUs addressed in this BA would likely use similar habitat in the action area. Therefore, the direct and indirect effects on delta smelt, longfin smelt, Central Valley fall/late fall–run Chinook salmon, Central Valley steelhead, and green sturgeon are discussed together. Effects on Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon, which are unlikely to occur in the action area but may occasionally occur as strays, would be similar.

TEMPORARY CONSTRUCTION-RELATED EFFECTS

The Phase 3 Repair Project would include constructing several cutoff walls, which would entail degrading the top one-third to one-half of the levee, beginning with a 1:1 cut at the waterside crown. Implementing cutoff walls as part of the Phase 3 Repair Project would disturb soils along the top of the levee, which could enter the San Joaquin River through wind and water erosion. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately could be pumped into the San Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff. Waters (1995) evaluated the effects of turbidity and siltation in waterways at various exposure levels. Prolonged exposure to high levels of suspended sediment could create a loss of visual capability in fish, leading to a reduction in feeding and growth rates, and to a thickening of the gill epithelia, which may cause the loss of respiratory function; clogging and abrasion of gill filaments; and increases in stress levels, reducing the tolerance of fish to disease and toxicants (Waters 1995). Also, high levels of suspended sediments could cause the movement and redistribution of fish populations or other aquatic organisms, and could affect physical habitat (Waters 1995). Sediment loading could interfere with photosynthesis of aquatic flora and displace aquatic fauna. Many fish and other aquatic species are sight feeders, and turbid waters would reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, could become disoriented and leave areas where their main food sources are located, ultimately reducing their growth rates. Increased turbidity and sedimentation cause fish to avoid an area, thus reducing available habitat. Fish will not occupy areas unsuitable for survival unless they have no other option. Therefore, construction-related erosion could result in elevated river turbidity in critical species-specific and life stage-specific habitats, potentially precluding a species from occupying that habitat. In addition, the potential would exist for contaminants (such as bentonite slurry, fuels, oils, and other products used in construction) to be introduced into the waterway directly or through surface runoff. Contaminants may be toxic to fish, or may alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival.

Through implementation of the water quality BMPs, including a SWPPP, and BMPs for slurry management and a slurry spill contingency plan, the proposed conservation measures (see the "Avoidance and Minimization Measures" section in this BA) would avoid direct and indirect take of fish during construction. The Phase 3 Repair Project would not be expected to have an effect on the overall continued existence and survival of these species.

PERMANENT CONSTRUCTION-RELATED EFFECTS

Most waterside woodlands in the Phase 3 Repair Project area are assumed to provide SRA habitat functions. Apart from the placement of 0.64 acre of riprap above the HTL along the waterside levee along 740 linear feet at element IVc, the Phase 3 Repair Project would not include performing any work on the waterside of the levee, and no waterside woodlands or SRA habitat would be removed. Therefore, construction-related effects on the habitats of federally listed fish species would be limited to minor disturbance of the waterside levee at three locations that are above the HTL and characterized by ruderal vegetation.

RD 17 would continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which would include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). Because vegetation management would be limited to trimming trees, no trees would be removed; thus, no change would occur in the amount of waterside habitat that would be directly affected and removed because of future vegetation management activities.

The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed because of construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed because of Phase 3 Repair Project construction (3.28 acres; see **Table 6**) but none would be removed because of future vegetation management activities.

Because all Phase 3 Repair Project construction activities would occur above the HTL and no SRA habitat would be removed during Phase 3 Repair Project construction or future vegetation management activities, the Phase 3 Repair Project would not result in adverse effects on Central Valley steelhead, Delta smelt, longfin smelt, Sacramento River winter-run and Central Valley fall- and spring-run Chinook salmon, or green sturgeon.

BENEFITS OF PROJECT ACTIONS TO REARING SALMONIDS

Construction of a 1,240-foot-long setback levee with cutoff wall and seepage berm on a major oxbow of the San Joaquin River (see **Table 2**) would directly benefit fish resources. A Conceptual MMP has been prepared to describe the planned expansion and restoration of riparian habitat that would occur in element IVc (**Appendix E**).

Approximately 0.64 acres (740 linear feet) of riprap would be installed on the waterside of the existing levee (above the HTL), where it would intersect the setback levee. After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 5 acres of floodplain to the river. That floodplain area would be graded to allow complete drainage of the floodplain to the river through the downstream opening in the remnant levee, as river flows recede. This would minimize the possibility of fish stranding. The other major benefit to fish resources would be the creation of approximately 5 acres of floodplain rearing habitat for juvenile salmonids, in particular, but also to other native fishes. The seasonal nature of inundation, along with complete drainage, would preclude establishment in the floodplain of predatory, non-native fishes.

The specific elevation of the levee breach invert elevation is under consideration. The primary purpose of the setback levee would be to provide habitat for the riparian brush rabbit. The invert elevation and the floodplain elevation would be based on site constraints, habitat requirements, and balancing the needs of riparian brush rabbit to provide protection to any individuals during high-water events while providing a level of disturbance that would support riparian scrub habitat in a sustainable way. The levee breach invert is expected to be set at an elevation to inundate approximately every 3 to 4 years, and the lower floodplain would inundate approximately every 6 years. A detailed hydraulic analysis of the surface water hydrology anticipated within the levee setback area, based on three possible levee breach invert elevations, is provided in the Conceptual MMP (**Appendix E,** see "Mitigation Site Baseline, Hydrology," and **Appendix B**). The floodplain habitat would not be permanently inundated and would not be connected to the San Joaquin River during the dry season.

Jeffries et al. (2008) reared juvenile Chinook salmon in enclosures for two consecutive flood seasons within various habitats of the Cosumnes River and its floodplain, to compare fish growth in river channel and floodplain habitats. Significant differences in growth rates were found; salmon reared in seasonally inundated habitats with annual terrestrial vegetation experienced higher growth rates than those reared in a perennial pond on the floodplain. Furthermore, riverine fish growth upstream from the floodplain varied with flow in the river; with little growth and high mortality during high-water events. When stream flows were low and clear, fish growth was rapid. Growth rates were poor in tidally influenced riverine habitat below the floodplain, where juveniles commonly were displaced during high-water events because of a lack of in-channel complexity. Overall, ephemeral floodplain habitats supported higher growth rates for juvenile Chinook salmon than more permanent habitats in either the floodplain or river. Variable responses in both growth and mortality, however, indicate the importance of providing habitat complexity for juvenile salmon in floodplain reaches of streams, so fish can find optimal places for rearing under different flow conditions. Habitat complexity allows juvenile salmon to find cover, thereby reducing the risk of predation from avian and piscine predators. Floodplain and other off-channel habitat restoration are important for improving production of juvenile salmonids in California's Central Valley. Juvenile salmonid emigration generally is passive during high-water events (Healey 1980; Kjelson et al. 1981); they essentially are entrained in the water column until they encounter slower water velocities, where active swimming becomes possible. The San Joaquin River, like most rivers in the Central Valley, is incised and lacks channel complexity. With the exception of the Yolo Bypass for the Sacramento River (Sommer et al. 2001), juvenile salmonids frequently are displaced downstream to the intertidal Delta, where growth is diminished during high-water events in systems that lack access to floodplains. However, protected floodplain habitat provides protection for juvenile salmonids being swept downstream during high-water events.

High San Joaquin River outflows generally occur during winter and early spring months. Juvenile fall/late fall-run Chinook salmon and steelhead outmigration occurs at least partially during this period, while spring-run Chinook salmon and green sturgeon outmigration occurs later.

- Central Valley fall/late fall-run Chinook salmon juvenile outmigration may begin as early as November and extends through June.
- Central Valley spring-run Chinook salmon juvenile outmigration generally occurs from April through June.
- Central Valley steelhead juvenile outmigration generally occurs from December through March in the San Joaquin River, and continues through June in the Delta.
- North American green sturgeon outmigration of older juveniles generally occurs from June through September.

The presence of the protected floodplain likely would benefit juvenile fall/late fall-run Chinook salmon and steelhead during high-water events. The configuration of the floodplain being protected during high-water events would facilitate protection of juvenile salmonids as they are directed into the floodplain through backflow currents and are not displaced any further downstream.

Sommer et al. (2001) provided evidence that the Yolo Bypass, the primary floodplain of the lower Sacramento River, provides better rearing and migration habitat for juvenile Chinook salmon than adjacent river channels. During 1998 and 1999, salmon increased in size substantially faster in the seasonally inundated agricultural floodplain than in the river, suggesting better growth rates. Similarly, coded-wire-tagged juveniles released in the floodplain were substantially larger at recapture and had higher apparent growth rates than those concurrently released in the river. Improved growth rates in the floodplain were in part because of substantially higher prey consumption, reflecting greater availability of drift invertebrates. Bioenergetic modeling suggested that feeding success was greater in the floodplain than in the river, despite increased metabolic costs of rearing in the substantially warmer floodplain. Growth, survival, feeding success, and prey availability were higher in 1998 than in 1999, a year in which flow was more moderate, indicating that hydrology affects the quality of floodplain rearing habitat. These findings support the predictions of the flood pulse concept and provide new insight into the importance of the floodplain for salmon.

Work by Jeffries et al. (2008) and Sommer et al. (2001) indicate that off-channel floodplain habitats provide substantially improved rearing habitat, supporting higher growth rates than the intertidal river channel. However, their work shows that providing habitat complexity for juvenile salmon in floodplains is of utmost importance, so fish can find optimal places for rearing under varying flow conditions. It is well documented that survivorship to adulthood is increased when young salmonids leave freshwater at a larger size (Unwin 1997; Galat and Zweimuller 2001). Studies by Jeffries et al. (2008), Sommer et al. (2001), and others show that floodplain habitat restoration in Central California has major benefits to Chinook salmon populations, especially relative to growth and production. These studies indicate bioenergetic improvement to salmonids rearing in a flooded terrestrial floodplain because of the abundance of zooplankton (primary production), rather than having to rely on less dense prey items in the riverine channels, such as larval fish and benthic macroinvertebrates, and expending more energy for their capture. Therefore, construction of element IVc would be likely to result in bioenergetic improvement for all listed species.

CUMULATIVE EFFECTS

Cumulative effects include the effects of present, pending, and future State, tribal, local, or private actions that are reasonably certain to occur in the action area under consideration. The effects of projects that require a federal action are not considered in the cumulative effects evaluation during Section 7 consultation evaluation because they are subject to separate consultation (USFWS and NMFS 1998). For example, the Central Lathrop Specific Plan (Phase 1) addresses the development of 1,521 acres of land immediately east of the RD 17 levee elements IIIa and IIIb, south of Dos Reis and north of the housing development adjacent to element IVa. The USFWS issued a Biological Opinion for this project (USFWS File No. 1-1-06-F-0114), which analyzed the effects of the project on riparian brush rabbit and VELB. Therefore, this development is not considered cumulative to the proposed project. Also, the nonfederal action must be located in the action area, or project site, that is evaluated in the Section 7 consultation process (USFWS and NMFS 1998). Several present, pending, and future projects that are located in or near the action area under consideration in this consultation could result in effects similar to those of the proposed action.

SUMMARY OF PRESENT, PENDING, AND FUTURE PROJECTS IN THE PHASE 3 REPAIR PROJECT AREA

FLOOD DAMAGE REDUCTION SYSTEM IMPROVEMENTS

Two other proposed projects related to improvements to flood damage reduction systems are located near RD 17: the Lower San Joaquin River Feasibility Study, which would determine needed improvements for future flood protection systems in an effort to reach or exceed the future 200-year level of flood protection; and the Smith Canal Closure Structure, which would install a flood control gate in the Delta in Stockton, north of the Deep Water Ship Channel, to prevent flood flows from entering the Smith Canal in the event of an imminent or existing levee breach and during 100-year flood events.

These projects may affect federally listed species and require a federal action, and therefore would be subject to Section 7 consultation. Where adverse effects would occur on the landside of the levees, the project proponents may need incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Repair Project because they would undergo federal review and permitting as necessary—either through a Section 7 consultation or through SJMSCP compliance. This would ensure that adverse effects would be fully mitigated.

DEVELOPMENT PROJECTS

Development projects within the RD 17 boundaries include projects in the cities of Manteca, Stockton, and Lathrop, and in unincorporated areas of San Joaquin County. These projects have been described and analyzed in their respective environmental documents, including the following:

- River Islands Project;
- San Joaquin County General Plan 2010, adopted in 1992 and as amended;
- City of Stockton General Plan, adopted in 1990 and as amended through November 3, 1998;
- City of Lathrop General Plan, adopted in 1991 and as amended through January 2003;
- Central Lathrop Specific Plan, adopted in November 2004;

- West Lathrop Specific Plan, adopted in 1995;
- Manteca General Plan, adopted in 1988 and as amended through December 20, 1993;
- City of Lathrop Water, Wastewater, and Recycled Water Master Plan, adopted in 2001 and as amended through November 9, 2004;
- City of Manteca Wastewater Treatment Plant expansion; and
- 2001 Regional Transportation Plan, San Joaquin Council of Governments, 2001.

San Joaquin County covers approximately 909,000 acres, with approximately 809,000 acres (or nearly 90 percent of the county) used or available for agriculture (i.e., row and field crops, orchards, vineyards, and grazing lands). The remaining lands are dominated by various types of development (approximately 59,000 acres), natural habitats (e.g., woodlands, riparian), and open water (e.g., lakes, rivers, Delta waterways). Most county residents and development are located in incorporated cities (i.e., Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton, and Tracy). The SJMSCP anticipated that 147,000 acres of various categories of open space lands (including agriculture, range lands, and natural) in the county would be converted to non–open space uses between 2001 and 2051, based on full buildout of each of the general plans in the county and construction of all anticipated utility, transportation, and other public projects. In addition, approximately 59,000 acres of infill of urban lands were presumed to occur in this 50-year time frame.

Many development projects near the Phase 3 Repair Project area, including those described above, have been implemented recently or are in various stages of planning and entitlement, including the River Islands project. These current, pending, and potential future projects may affect federally listed species and require a federal action, and therefore would be subject to Section 7 consultation. Or, for those occurring within the SJMSCP permit area within San Joaquin County, the project applicants are expected to seek incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Repair Project because they would undergo federal review and permitting as necessary—either through Section 7 consultation or SJMSCP compliance.

ANALYSIS OF CUMULATIVE EFFECTS

GROWTH INDUCEMENT

Direct growth inducement would result if a project would include construction of new housing. Indirect growth inducement would occur, for instance, if implementing a project were to result in any of the following:

- substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises);
- substantial short-term employment opportunities (e.g., construction employment) that indirectly would stimulate the need for additional housing and services to support the new temporary employment demand; and/or
- removal of an obstacle to additional growth and development, such as removing a constraint on a required public utility or service (e.g., construction of a major sewer line with excess capacity through an undeveloped area).

Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density, or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Local land use decisions are within the jurisdiction of the cities and county in the Phase 3 Repair Project area: the City of Stockton, the City of Lathrop, the City of Manteca, and San Joaquin County. Each of these entities has adopted a General Plan consistent with State law. These General Plans provide an overall framework for growth and development within the jurisdiction of each agency, including the Phase 3 Repair Project area. Within the RD 17 boundaries, as elsewhere, population growth and urban development also are influenced by national, regional, and local economic conditions.

Because the Phase 3 Repair Project would not include construction of housing, it would not directly induce growth. Construction activities would generate short-term employment, but project-related construction jobs are expected to be filled from the existing local employment pool and not to indirectly induce growth or result in a population increase, nor would implementation of the project indirectly induce growth by creating permanent new jobs.

The Phase 3 Repair Project would accommodate growth currently approved or planned for undeveloped lands within the RD 17boundaries. These lands have been identified as the places most suitable for urban growth in the General Plans and additional planning policy documents of the cities of Lathrop, Manteca, and Stockton, and San Joaquin County. The Phase 3 Repair Project would allow development to proceed when economic and market conditions are favorable.

Development within the RD 17 boundaries is directed by the Central Lathrop Specific Plan and the West Lathrop Specific Plan in the City of Lathrop, the City of Stockton General Plan, the City of Manteca General Plan, and the San Joaquin County General Plan. The cities of Lathrop and Manteca are where the majority of planned or proposed development projects would be located. Environmental documents have been prepared to address the General Plans in these areas.

This information provides substantial evidence that the Phase 3 Repair Project would accommodate anticipated growth in a manner that would be consistent with adopted local growth management plans and with the State Plan of Flood Control. Thus, the Phase 3 Repair Project, despite accommodating buildout of adopted Specific Plans and General Plans in the cities of Lathrop, Manteca, and Stockton, would not be growth inducing itself.

Cumulative Effects on Listed Species

Implementing the plans and projects described above would permanently disturb undeveloped land that currently is or has recently been in agricultural use. These projects would have cumulative effects on agricultural resources (by converting agricultural land to nonagricultural uses) and remnant native habitats (such as woodlands and marshes), which would have the potential to cause permanent adverse cumulative effects on the species, including federally listed species, for which these lands provide habitat.

Large areas of native riparian and wetland vegetation in the Phase 3 Repair Project area and Central Valley region have been lost or degraded over the past 150 years. USFWS estimates that more than 90 percent of wetland and riparian habitat has been lost in the Central Valley, compared to historic levels (USFWS 1989). Most losses have occurred because of CVP and SWP facility construction and alteration of flow patterns below dams, particularly channelization, and then clearing or filling behind levees for the conversion to agriculture and urban land uses. Alterations to the San Joaquin River channel have resulted over time in homogenous, trapezoidal channels with little instream structure; narrow and sparse bands of riparian vegetation that provide only limited SRA habitat functions; limited recruitment of large woody debris; and limited habitat conditions for native fish species and other aquatic organisms. This habitat conversion has affected many plant and wildlife species substantially, resulting in various species being listed as threatened or endangered under the ESA as well as under the California Endangered Species Act.

Present and future conversions of open space lands in San Joaquin County and the region consist primarily of converting agricultural lands to residential and urban development. Several flood risk management projects are

being implemented across the Central Valley, including San Joaquin County, to improve the integrity of levees. However, some of these flood risk management projects would implement compensatory mitigation in the form of habitat creation and preserves, designed to actually increase these habitats and their values related to ecosystem functions and special-status species. Upstream from the Phase 3 Repair Project area, the SJRRP would result in future structural and channel improvements to benefit special-status fish and wildlife species (Reclamation and DWR 2011). Nevertheless, even with these benefits, the overall losses of sensitive habitats in the Phase 3 Repair Project region, the numerous threatened and endangered species that are present, the ongoing declines of other species, and the continuing conversions of habitats and open space lands to various developments are evidence that past, present, and reasonably foreseeable future projects would combine to result in significant cumulative effects on biological resources.

Development projects (i.e., residential, commercial, industrial), infrastructure projects, and flood facilities improvement projects include or would include grading and other earthmoving activities that could result in temporary and short-term localized soil erosion that could affect hydrology and would have the potential to release materials (e.g., runoff of soils or contaminants) into the San Joaquin River. Potential increases in sedimentation, turbidity, and contaminants could expose and adversely affect fish and aquatic habitats. However, these site-specific effects are not expected to combine with the effects of other activities, because compliance with the NPDES regulations, including construction site BMPs, would help control erosion at each construction site. The effects from development projects, infrastructure projects, and flood facilities improvement projects would be temporary and short-term, and soil erosion would be localized.

CONCLUSIONS AND DETERMINATION

In conclusion, based on the biology and ecology of the federally listed species that have the potential to occur in the Phase 3 Repair Project area, the environmental baseline for the action area, and the effects of the proposed action and its cumulative effects, implementing the Phase 3 Repair Project may affect and is likely to adversely affect VELB and riparian brush rabbit, and would result in no adverse effect on delta smelt, Central Valley fall/late fall–run Chinook salmon, Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, and green sturgeon. Designated critical habitat in the action area has been designated for delta smelt, Central Valley steelhead, and green sturgeon; however, none would be adversely modified or destroyed.

- **Valley elderberry longhorn beetle:** The Phase 3 Repair Project may affect and is likely to adversely affect VELB by transplanting eight elderberry shrubs. Although VELB habitat credits comparable to 367 elderberry seedlings and 367 associated native plantings would be purchased from a USFWS-approved VELB habitat conservation bank to compensate for effects on VELB and effects on 268 elderberry stems (greater than 1 inch in diameter at ground level), an adverse effect on the species could occur. Removal of shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected, and a temporary loss of habitat available to the beetle during the establishment of seedlings would occur.

- **Riparian brush rabbit:** The Phase 3 Repair Project may affect and is likely to adversely affect riparian brush rabbit by removing 3.28 acres of landside riparian habitat that is suitable for the species, contributing to the further reduction of available habitat for this species.

However, the Phase 3 Repair Project would include restoring approximately 4.52 acres of compensatory riparian habitat (**Exhibit 12**) to offset project-related habitat losses. After the new setback levee in element IVc is constructed and certified, a small section of the existing levee then would be partially degraded. Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4.52 acres that could be restored as riparian habitat (**Exhibit 12**). The restored riparian habitat would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where this species is documented to occur along the RD 17 levees. Apart from a small notch along the north side, the existing levee would remain in place, thus providing upland refugia for the species during high-water events. The 4.52-acre area would be contiguous with existing waterside riparian habitat along element IVc; this waterside riparian habitat along element IVc extends northward through elements IVa, IIIa, and IIIb, and southward through elements Va and VIa.1. Documented occurrences exist of riparian brush rabbit in the waterside riparian habitat in elements IIIa and IIIb, north of element IIIa and south of element VIa.1; therefore, reestablishing and protecting riparian habitat in element IVc would provide expanded and connected habitat for this species.

RD 17 also is evaluating options for providing off-site compensatory habitat to offset Phase 3 Repair Project effects on riparian brush rabbit. Additional off-site compensatory habitats would include preserving existing waterside riparian habitats and/or restoring natural riparian habitats. These options would be evaluated in coordination with USFWS during the Section 7 consultation.

- **Federally listed fish species:** The Phase 3 Repair Project would result in no adverse effects on federally proposed and federally listed fish species considered in this BA. Effects are not expected to occur because of the avoidance and minimization measures to be implemented by the Phase 3 Repair Project. The Phase 3 Repair Project would include several measures that would avoid potential direct environmental effects during project construction. The potential effects of increased sedimentation or turbidity, and/or release of contaminants on fish and other aquatic organisms, would be avoided and minimized through the use of BMPs (e.g., source control, detention basins, revegetation, and spill containment plan) that would maintain surface water quality conditions in receiving waters and minimize disturbance to fish and other aquatic habitats. No waterside riparian or SRA habitat would be removed.

ESSENTIAL FISH HABITAT ASSESSMENT

The Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801), requires that EFH be identified and described in federal fishery management plans. Federal agencies must consult with NMFS on any activity that they fund, permit, or carry out that may adversely affect EFH. The EFH regulations require that federal agencies obligated to consult on EFH also provide NMFS with a written assessment of the effects of any action on EFH (50 CFR 600.920). NMFS is required to provide EFH conservation and enhancement recommendations to federal agencies. The statute also requires federal agencies receiving NMFS EFH conservation recommendations to provide a detailed written response to NMFS within 30 days of receipt, detailing how they intend to avoid, mitigate, or offset the impact of activity on EFH (Section 305[b][4][B]).

EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. For the purposes of interpreting the definition of EFH, "waters" includes aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include areas historically used by fish where appropriate; "substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities; "necessary" means habitat required to support a sustainable fishery and a healthy ecosystem; and "spawning, breeding, feeding, or growth to maturity" covers all habitat types used by a species throughout its life cycle.

The Pacific Fishery Management Council has identified and described EFH, adverse impacts, and recommended conservation measures for salmon in Amendment 14 to the Pacific Coast Salmon Fishery Management Plan (PFMC 2003). Amendment 18 to the Pacific Coast Salmon Fishery Management Plan revises the description and identification of EFH for Pacific salmon, designates habitat areas of particular concern, modifies the current information on fishing activities and potential measures to minimize their effects on EFH, and updates the list of fishing and non-fishing related activities that may adversely affect EFH and potential conservation and enhancement measures to minimize those effects (NMFS 2014c). Freshwater EFH for Pacific salmon in the Central Valley (i.e., Chinook salmon) includes waters currently or historically accessible to salmon within the Central Valley ecosystem, as described in Myers et al. (1998), and includes the segment of the San Joaquin River in the action area. EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia from high flows during floods as salmon migrate along the mainstem in this area. Although evidence of current or historical Chinook salmon distribution is lacking for the western tributaries (Yoshiyama et al. 2001), the lower reaches of these tributaries could provide juvenile rearing habitat or refugia. Central Valley fall/late fall–run Chinook salmon is a species managed under the Pacific Coast Salmon Plan that occurs in the San Joaquin River.

THE PROPOSED ACTION

The proposed action is described in detail in the "Description of the Proposed Action" section of this BA. The action area, environmental baseline, and species accounts, respectively, are described in the "Action Area," "Environmental Baseline," and "Species Accounts" sections of this BA.

ESSENTIAL FISH HABITAT DESIGNATION IN THE ACTION AREA

EFH has been identified for Chinook salmon, which includes Central Valley fall- and late fall-run Chinook salmon. EFH includes migration, holding, and rearing habitat and opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014a). EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia during floods as salmon migrate along the mainstem in this area (NMFS 2014c).

EFFECTS OF THE PROPOSED ACTION

Effects of the proposed action are described below and in the "Effects" and "Cumulative Effects" sections of this BA.

Available literature indicates that limited Chinook salmon spawning typically occurs well upstream from the Phase 3 Repair Project area. EFH in the San Joaquin River in the vicinity of the Phase 3 Repair Project area consists of adult and juvenile (smolt) Chinook salmon passage between upstream spawning grounds and the Pacific Ocean, and limited in-channel rearing habitat for juveniles (limited because it is situated in a reach of the San Joaquin River that is bound on both banks by levees, resulting in channel incision, and is disconnected from its currently non-functioning floodplain). The river extends onto its floodplain only during high-water events, and if fish are swept into the floodplain during high flow conditions, they likely would become stranded because of the absence of a secondary channel for returning flood flows to the river. The Phase 3 Repair Project would result in improvement of EFH as functioning floodplain-rearing habitat and improvement to existing EFH in the San Joaquin River channel, by reducing and reversing the effects of current channel incision in the immediate vicinity of element IVc. Furthermore, approximately 2.5 acres of SRA habitat would be created and/or enhanced through revegetation actions between the river and the waterside toe of the existing levee in element IVc (see **Appendix E**).

Levee degradation and floodplain grading activities in element IVc would restore connectivity to the historic floodplain and improve habitat conditions in the floodplain. Although both actions would be constructed in dry conditions (above HTL), a potential short-term indirect effect of construction may be a temporary increase in sediment in the San Joaquin River, especially during the first storm or flooding event after construction. The measures (erosion control and revegetation) described in the "Avoidance and Minimization Measures" section of this BA are designed to reduce or capture any mobilized sediment resulting from the year's first rain or flooding event. Therefore, any construction-related sediment load would be temporary and negligible, especially when compared to the existing sediment load of the San Joaquin River and the project would not result in adverse effects on EFH.

The project would increase the amount and improve the quality of EFH in the project area. The new setback levee with floodplain in element IVc would improve EFH by providing refuge habitat for juvenile salmonids during high-water events, as described in Amendment 18 (NMFS 2014c). The newly reconnected floodplain would provide habitat for juvenile Chinook salmon rearing. It would also alter the channel dynamics in the immediate vicinity such that the channel incision process is expected to be reversed, thereby improving juvenile and adult migratory passage habitat.

PROPOSED CONSERVATION MEASURES

Proposed conservation measures are presented in the "Description of the Proposed Action" and "Effects" sections of this BA. The measures include avoidance and minimization measures.

CONCLUSIONS

The proposed action would not affect the spawning, rearing, or migratory EFH functions of Chinook salmon currently or previously managed under the Magnuson-Stevens Fishery Conservation and Management Act in the San Joaquin River.

Consultation Code: 08FBDT00-2016-SLI-0118 April 18, 2016
Event Code: 08FBDT00-2016-E-00075
Project Name: RD 17 Levee Seepage Repair Project - Phase 3

Subject: List of threatened and endangered species that may occur in your proposed project location, and/or may be affected by your proposed project

To Whom It May Concern:

The enclosed species list identifies threatened, endangered, proposed and candidate species, as well as proposed and final designated critical habitat, that may occur within the boundary of your proposed project and/or may be affected by your proposed project. The species list fulfills the requirements of the U.S. Fish and Wildlife Service (Service) under section 7(c) of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 *et seq.*).

New information based on updated surveys, changes in the abundance and distribution of species, changed habitat conditions, or other factors could change this list. Please feel free to contact us if you need more current information or assistance regarding the potential impacts to federally proposed, listed, and candidate species and federally designated and proposed critical habitat. Please note that under 50 CFR 402.12(e) of the regulations implementing section 7 of the Act, the accuracy of this species list should be verified after 90 days. This verification can be completed formally or informally as desired. The Service recommends that verification be completed by visiting the ECOS-IPaC website at regular intervals during project planning and implementation for updates to species lists and information. An updated list may be requested through the ECOS-IPaC system by completing the same process used to receive the enclosed list.

The purpose of the Act is to provide a means whereby threatened and endangered species and the ecosystems upon which they depend may be conserved. Under sections 7(a)(1) and 7(a)(2) of the Act and its implementing regulations (50 CFR 402 *et seq.*), Federal agencies are required to utilize their authorities to carry out programs for the conservation of threatened and endangered species and to determine whether projects may affect threatened and endangered species and/or designated critical habitat.

A Biological Assessment is required for construction projects (or other undertakings having similar physical impacts) that are major Federal actions significantly affecting the quality of the human environment as defined in the National Environmental Policy Act (42 U.S.C. 4332(2) (c)). For projects other than major construction activities, the Service suggests that a biological evaluation similar to a Biological Assessment be prepared to determine whether the project may affect listed or proposed species and/or designated or proposed critical habitat. Recommended contents of a Biological Assessment are described at 50 CFR 402.12.

If a Federal agency determines, based on the Biological Assessment or biological evaluation, that listed species and/or designated critical habitat may be affected by the proposed project, the agency is required to consult with the Service pursuant to 50 CFR 402. In addition, the Service recommends that candidate species, proposed species and proposed critical habitat be addressed within the consultation. More information on the regulations and procedures for section 7 consultation, including the role of permit or license applicants, can be found in the "Endangered Species Consultation Handbook" at:

http://www.fws.gov/endangered/esa-library/pdf/TOC-GLOS.PDF

Please be aware that bald and golden eagles are protected under the Bald and Golden Eagle Protection Act (16 U.S.C. 668 *et seq.*), and projects affecting these species may require development of an eagle conservation plan (http://www.fws.gov/windenergy/eagle_guidance.html). Additionally, wind energy projects should follow the wind energy guidelines (http://www.fws.gov/windenergy/) for minimizing impacts to migratory birds and bats.

Guidance for minimizing impacts to migratory birds for projects including communications towers (e.g., cellular, digital television, radio, and emergency broadcast) can be found at: http://www.fws.gov/migratorybirds/CurrentBirdIssues/Hazards/towers/towers.htm; http://www.towerkill.com; and http://www.fws.gov/migratorybirds/CurrentBirdIssues/Hazards/towers/comtow.html.

We appreciate your concern for threatened and endangered species. The Service encourages Federal agencies to include conservation of threatened and endangered species into their project planning to further the purposes of the Act. Please include the Consultation Tracking Number in the header of this letter with any request for consultation or correspondence about your project that you submit to our office.

Consultation Code: 08FBDT00-2016-SLI-0118
Event Code: 08FBDT00-2016-E-00075

Project Type: STREAM / WATERBODY / CANALS / LEVEES / DIKES

Project Name: RD 17 Levee Seepage Repair Project - Phase 3
Project Description: The overall purpose of the Phase 3 Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.3 miles of the approximately 19-mile RD 17 levee system to improve the existing levee integrity based on the new USACE standards and continue to provide flood risk reduction within RD 17 and surrounding areas. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation.

Please Note: The FWS office may have modified the Project Name and/or Project Description, so it may be different from what was submitted in your previous request. If the Consultation Code matches, the FWS considers this to be the same project. Contact the office in the 'Provided by' section of your previous Official Species list if you have any questions or concerns.

Endangered Species Act Species List

There are a total of 9 threatened or endangered species on your species list. Species on this list should be considered in an effects analysis for your project and could include species that exist in another geographic area. For example, certain fish may appear on the species list because a project could affect downstream species. Critical habitats listed under the **Has Critical Habitat** column may or may not lie within your project area. See the **Critical habitats within your project area** section further below for critical habitat that lies within your project. Please contact the designated FWS office if you have questions.

Amphibians	Status	Has Critical Habitat	Condition(s)
California red-legged frog *(Rana draytonii)* Population: Entire	Threatened	Final designated	
California tiger Salamander *(Ambystoma californiense)* Population: U.S.A. (Central CA DPS)	Threatened	Final designated	
Crustaceans			
Vernal Pool fairy shrimp *(Branchinecta lynchi)* Population: Entire	Threatened	Final designated	
Vernal Pool tadpole shrimp *(Lepidurus packardi)* Population: Entire	Endangered	Final designated	
Fishes			
Delta smelt *(Hypomesus transpacificus)* Population: Entire	Threatened	Final designated	
Flowering Plants			

Large-Flowered fiddleneck *(Amsinckia grandiflora)*	Endangered	Final designated	
Insects			
Valley Elderberry Longhorn beetle *(Desmocerus californicus dimorphus)* Population: Entire	Threatened	Final designated	
Mammals			
Riparian Brnsh rabbit *(Sylvilagus bachmani riparius)* Population: Entire	Endangered		
Reptiles			
Giant Garter snake *(Thamnophis gigas)* Population: Entire	Threatened		

Critical habitats that lie within your project area

The following critical habitats lie fully or partially within your project area.

Fishes	Critical Habitat Type
Delta smelt *(Hypomesus transpacificus)* Population: Entire	Final designated

Subject: Species List for RD 17 Levee Seepage Area Project

Dear: Ms. Holland

We are sending this official species list in response to your February 27, 2014 request for information about endangered and threatened species. The list covers the California counties and/or U.S. Geological Survey 7½ minute quad or quads you requested.

Our database was developed primarily to assist Federal agencies that are consulting with us. Therefore, our lists include all of the sensitive species that have been found in a certain area *and also ones that may be affected by projects in the area*. For example, a fish may be on the list for a quad if it lives somewhere downstream from that quad. Birds are included even if they only migrate through an area. In other words, we include all of the species we want people to consider when they do something that affects the environment.

Please read Important Information About Your Species List (below). It explains how we made the list and describes your responsibilities under the Endangered Species Act.

Our database is constantly updated as species are proposed, listed and delisted. If you address proposed and candidate species in your planning, this should not be a problem. However, we recommend that you get an updated list every 90 days. That would be May 28, 2014.

Please contact us if your project may affect endangered or threatened species or if you have any questions about the attached list or your responsibilities under the Endangered Species Act. A list of Endangered Species Program contacts can be found here.

Quad Lists

Listed Species

Invertebrates

Branchinecta lynchi
- vernal pool fairy shrimp (T)

Desmocerus californicus dimorphus
- valley elderberry longhorn beetle (T)

Lepidurus packardi
- vernal pool tadpole shrimp (E)

Fish

Acipenser medirostris
- green sturgeon (T) (NMFS)

Hypomesus transpacificus
- Critical habitat, delta smelt (X)
- delta smelt (T)

Oncorhynchus mykiss
- Central Valley steelhead (T) (NMFS)
- Critical habitat, Central Valley steelhead (X) (NMFS)

Oncorhynchus tshawytscha
- Central Valley spring-run chinook salmon (T) (NMFS)
- winter-run chinook salmon, Sacramento River (E) (NMFS)

Amphibians

Ambystoma californiense
- California tiger salamander, central population (T)

Rana draytonii
- California red-legged frog (T)

Reptiles

Thamnophis gigas
- giant garter snake (T)

Mammals

Sylvilagus bachmani riparius
- riparian brush rabbit (E)

Plants

Cordylanthus palmatus
- palmate-bracted bird's-beak (E)

Appendix C

Evaluation of Potential for Giant Garter Snake Occurrence in the Phase 3 Repair Project Area

EVALUATION OF POTENTIAL FOR GIANT GARTER SNAKE TO OCCUR IN THE PHASE 3 PROJECT AREA

This appendix describes the evaluation process undertaken to determine whether the giant garter snake *(Thamnophis gigas),*which is federally and state-listed as threatened, could occur in the Phase 3 Project area of Reclamation District 17's (RD 17) Levee Seepage Repair Project (Phase 3 Project or proposed project). This evaluation supports the conclusion stated in Table 1 of the Biological Assessment: the giant garter snake is unlikely to occur in the Phase 3 Project area.

Table 1 in the Biological Assessment summarizes an assessment of the potential for species, which have been termed "threatened" or "endangered" under the jurisdiction of U.S. Fish and Wildlife Service and National Marine Fisheries Service, to occur in the Phase 3 Project Area. A number of resources were consulted to generate the list of species that would be evaluated (CNBBD 2014; CNPS 2014; USFWS 2014). Surveys of the proposed project area were also conducted to evaluate habitat conditions and habitat suitability for listed species. The majority of the federally listed species identified in Table 1of the Biological Assessment were eliminated from further consideration because they are not likely to occur in the Phase 3 Project area due to a lack of suitable habitat, local range restrictions, regional extirpations, or lack of connectivity between areas of suitable or occupied habitat, or because the action area is located outside of the extant range of the species.

The giant garter snake was determined to be unlikely to occur in the Phase 3 Project area because of a lack of suitable habitat, lack of connectivity to areas of suitable or occupied habitat, and local range restrictions. Information supporting this conclusion is detailed below.

LACK OF SUITABLE HABITAT

Giant garter snakes are endemic to wetlands in the Sacramento and San Joaquin valleys, where the species inhabits marshes, sloughs, ponds, small lakes, low gradient streams, and other waterways and agricultural wetlands, such as irrigation and drainage canals, rice fields and the adjacent uplands (USFWS 1999). Essential habitat components consist of: (1) wetlands with adequate water during the snake's active season (early-spring through mid-fall) to provide food and cover; (2) emergent, herbaceous wetland vegetation, such as cattails and bulrushes, for escape cover and foraging habitat during the active season; (3) upland habitat with grassy banks and openings in waterside vegetation for basking; and (4) higher elevation uplands for over-wintering habitat with escape cover (vegetation, burrows) and underground refugia (crevices and small mammal burrows) (Hansen 1988). Snakes are typically absent from larger rivers and other bodies of water that support introduced populations of large, predatory fish, and from wetlands with sand, gravel, or rock substrates (Hansen 1988; Hansen and Brode 1980; Rossman and Stewart 1987). Riparian woodlands do not provide suitable habitat because of excessive shade, lack of basking sites, and absence of prey populations (Hansen 1988). Unlike flood irrigated rice fields, other agricultural cropping systems (i.e., irrigation and drainage canals supporting "dry" row crops) do not hold sufficient water for long enough time periods to create artificial, temporary wetlands and also lack an adequate prey base (USFWS 2012; Wylie and Martin 2005).

According to the USFWS's most recent summary and evaluation report on the giant garter snake (USFWS 2012), the RD 17 project area falls within the Delta Basin "population," which includes portions of Sacramento, Yolo, Solano, Contra Costa, and San Joaquin counties. Although some suitable habitat for the giant garter snake is known to exist in the Delta Basin giant garter snake "population" (USFWS 2012), suitable habitat is not distributed evenly throughout the Lower San Joaquin River portion of the Delta Basin. Specifically, most of the RD 17 area and all of the Phase 3 Project area do not support suitable habitat for giant garter snake, as outlined below. The essential habitat components required by the species are not present in the proposed project area (E. Hansen, pers. comm., 2014). Potential aquatic habitat for the giant garter snake in the Phase 3 Project area is limited to one constructed pond in Element IIab; a small area of freshwater marsh in Element Ib; and a few agricultural ditches. However, these features are not considered suitable for the snake because: (1) these aquatic features are all isolated from one another, separated by overland distances of more than 200 feet, and are disconnected from other areas of potential aquatic habitat for the species and (2) these features capture periodic drainage from surrounding agricultural lands and, thus, are intermittently dry throughout the summer months, having water for limited and non-continuous periods. Wetlands that do not provide water during their active season (April to October) cannot support large populations of the giant garter snake (Wylie *et al*. 1997, 2000, 2002, 2010; USFWS 2012), mainly because these features lack both an adequate prey base and enough emergent vegetation that would provide cover and refuge for the species. Specifically, the aquatic features in the Phase 3 Project area are not suitable habitat for the giant garter snake based on the following reasons:

- Constructed Pond: The pond is a constructed feature that is stocked with predatory fish for recreational fishing. Predatory fish prey on the giant garter snake young as well as the snake's prey, limiting the snake's ability to maintain a population (G. Hansen 1986; CDFG 1992; USFWS 2012). Further, this pond is surrounded by residential landscape, which is not considered suitable upland for this species. Lastly, the pond is an isolated feature, separated from other potentially suitable aquatic habitats (e.g., agricultural ditches) by more than 1,000 feet.

- Freshwater Marsh: The freshwater marsh is fed by adjacent agricultural drainage ditches that are (1) intermittently dry throughout the snake's active season and (2) re-sculpted based on the farming needs each planting season, and therefore, are often filled, relocated, and otherwise subject to a great amount of ground disturbance. Because these ditches are not suitable habitat, the freshwater marsh remains a small, isolated feature surrounded by a landscape that is not suitable habitat for giant garter snake. The small size of this marsh and the high level of isolation render it unsuitable for the species.

- Agricultural Ditches: The agricultural ditches (1) lack emergent vegetation that serves to provide shelter to prey and shelter from predators; (2) are periodically dry throughout the snake's active season as these provide drainage catchment for "dry" agricultural fields (row crops), which are not suitable upland for the snake (Wylie and Martin 2005; USFWS 2012); and (3) are disconnected from each other and other aquatic habitats in the proposed project area and vicinity (Exhibit 1).

No suitable upland habitat is present in the Phase 3 Project area. Uplands consist mainly of urban and developed areas, residential and parks landscaping, and agricultural land, consisting of dry" row crops (e.g., tomatoes, corn), alfalfa, and orchards (RD 17 2009:12–15), which are not suitable as potential giant garter snake upland habitat (USFWS 2012).

Because the proposed project area lacks the essential habitat components required by the species (E. Hansen, pers. comm., 2014), the Phase 3 Project area does not support suitable habitat for giant garter snake.

LACK OF CONNECTIVITY

No occurrences of giant garter snake have been recorded in the RD 17 project area (CNDDB Two CNDDB occurrences of giant garter snake showed up in a California Natural Diversity Database (CNDDB) record search of the nine U.S. Geological Survey quadrangles that surround, and include, the proposed project. Both records are from 1976, including one in the Stockton Diverting Canal at State Route 99 (approximately 8 air miles northwest of the proposed project area; *see* Exhibit 1) and one along Eight Mile Road between Interstate 5 and State Route 99 (approximately 12 air miles north of the proposed project). The distance between these records to the proposed project area is a greater distance than the species is known to disperse across where suitable (and hydrologically connected) habitats are present (Wylie and Martin 2004); however, suitable habitat for the species is absent between these records and proposed project area and the hydrological connection is also not suitable.

The San Joaquin River provides the only hydrological connection between the proposed project site and these two records; as noted above under “Lack of Suitable Habitat,” large rivers, such as the San Joaquin River, are not suitable habitat for giant garter snake because of the absence of emergent vegetation and backwater sloughs, and the presence of predatory fish (Hansen 1988; Hansen and Brode 1980; Rossman and Stewart 1987). Both of the records are separated from the proposed project site by extensive urbanized development (City of Stockton), “dry” upland agricultural crops, and a large river, all of which do not provide suitable habitat for the giant garter snake (USFWS 2012). Although the region surrounding the RD 17 area appears to support abundant wetlands (e.g., west of the San Joaquin River or east of Interstate 5), the waters and wetlands within the RD 17 area are sparse and disconnected from each other and other areas where more extensive wetlands may be located (Exhibit 1). Not only does the RD 17 area not support suitable habitat for the species, this area is disconnected from areas where the species may or is known to occur, making it highly unlikely that the snake would exist, let alone persist, in the Phase 3 Project area (E. Hansen, pers. comm., 2014).

Waters with giant garter snake CNDDB Occurrences within a 10-mile Search Radius

LOCAL RANGE RESTRICTIONS

Apart from the two occurrence records referenced above, no other CNDDB records for this species are in the vicinity of the Phase 3 Project area. There are occurrences of the species documented in White Slough and Little Connection Slough, which are 15.5 and 15 miles due north of the proposed project, respectively, and in Volta Wildlife Area, which is over 50 miles south of the proposed project (USFWS 2012; CNDDB 2014). No occurrences of giant garter snakes are known from the northern portion of the San Joaquin Valley north to the eastern fringe of the Sacramento-San Joaquin River Delta, where the floodplain of the San Joaquin River is limited to a relatively narrow trough (Hansen and Brode 1980; 58 FR 54053). Any observations of the species in the Sacramento-San Joaquin River Delta are associated with backwater areas of the adjacent rivers, emergent marshes, and sloughs (E. Hansen, pers. comm., 2014) – all of which are absent from the waterside and landside of the RD 17 levees. The resulting gap of approximately 60 miles separates the southern and northern populations (Hansen and Brode, 1980; CNDDB 2014). The USFWS recognizes that this large gap (65 miles) between these occurrences of the giant garter snake is due to the presence of urbanized developments and “dry” agricultural crop production that do not provide suitable habitat for the species and limit its ability to disperse (USFWS 2012).

CONCLUSION

In summary, CNDDB records of GGS only indicate distribution of the species across the greater landscape; occurrence of the species within this landscape is limited to suitable and connected habitat (E. Hansen, pers. comm., 2014). There is no suitable habitat in the Phase 3 Project area that would support this species. Table 1 of the Biological Assessment summarizes the evaluation of potential for species occurrence in the proposed project area; this evaluation concluded that the giant garter snake is “unlikely to occur” in the Phase 3 Project area. An “unlikely to occur” determination concludes that potential habitat is present, but the species is unlikely to be present in the area because of current status of the species, a very restricted distribution, and/or essential habitat components are not present. Although some features in the proposed project area could be potential habitat for the species (e.g., annual grassland on the levee, freshwater marsh), these habitats are not suitable for the giant garter snake because they do not provide the components that are considered essential to support the species (e.g., a continuous supply of summer water, adequate prey base). Because of the absence of suitable habitat features and the lack of connectivity of the proposed project area to other areas that may be more suitable for the species, the species is unlikely to occur in the Phase 3 Project area (E. Hansen, pers. comm., 2014).

APPENDIX F-3

"Setback Levee Alternative" Excerpted from March 2, 2009, Reclamation District 17 Early Implementation Project Funding Application for 100-Year Levee Seepage Area Project – 2009 Project Elements

H. Setback Levee Alternative

The potential for setback levees along the San Joaquin River within RD 17 is limited due to the general ‘straightness’ of the channel and the proximity of developed adjacent land uses. However RD 17 has studied levee setback alternatives where the river alignment and adjacent land uses offer the potential for setback solutions. This setback levee analysis was conducted by ENGEO and considered geomorphic and hydraulic impacts that might result in the implementation of the setback levee alternatives. A copy of the analysis in included in Appendix 9.

RD17 identified a reach where channel geomorphology and undeveloped adjacent land might allow for the implementation of a setback levee. In the particular reach where the levee set-backs were considered, the San Joaquin River splits into two watercourses, at a prominent river bifurcation, as it flows towards the Delta area (Figure 11). The northern distributary continues as the eastern branch of the San Joaquin River, while the western distributary is referred to as the Old River. The RD 17 levees are constructed on the east (right) bank of the main and east branches of the San Joaquin River. The lands to the north of the San Joaquin River/Old River bifurcation are used for agriculture. In recent years a significant portion of the lands immediately southeast and southwest of the bifurcation have been converted from agricultural use to residential and commercial development.

<u>Setback Scenario 1</u>
Levee Setback Scenario 1 would remove a portion of the RD 17 levee located at a large bend in the river approximately between stations 685+00 and 610+00 and rebuild the levee so that the inboard area would become unprotected from flood flows. The setback levee would thus begin in the reach of the San Joaquin River upstream of the Old River bifurcation, and end downstream thereof.

<u>Setback Scenario 2</u>
Similar to Scenario 1, Scenario 2 would begin approximately at 685+00 but would continue through two river meanders approximately to station 590+00. Similar to Alternative 1, the set setback levee would thus begin in the reach of the San Joaquin River upstream of the Old River bifurcation, and end downstream thereof.

<u>Geomorphic Analysis:</u>
The geomorphic analysis of the setback levee scenarios included a review of surficial mapping by Atwater (1982), a previous study by William Lettis Associates (WLA, 2007), 1915 USGS topographic map for the Lathrop quadrangle and aerial photography flown between 1979 and 2003.

In the study area and to the north, the San Joaquin River splits into several distributary channels as it enters the Sacramento – San Joaquin Delta. Prior to levee construction in the late 1800’s the distributory channels flowed into and

ORIGINAL FIGURE PRINTED IN COLOR

through tidal marshes. According to Atwater (1982) and WLA (2003), the modern San Joaquin River system flows along the western edge of older alluvial fan deposits. The modern river channels and floodplains are underlain by Holocene alluvium consisting of stream channel deposits (sands and silts) and overbank deposits (sands, silts and clays). The distribution of Holocene alluvium and the morphology of the river channels has been influenced over the last several thousand years by rising sea levels and tidal effects from the adjacent Delta

On the 1915 topographic map, the locations of the main channel of the San Joaquin River and the bifurcation to the Old River appear to be essentially the same as the modern condition. The locations of the levees on the 1915 map also appear to be essentially the same as the modern condition, although the original levees were widened and raised in the 1960's. Review of aerial photographs flown between 1979 and 2003 shows that the channel morphology and levee conditions have remained relatively stable over the last three decades. Modifications to the levee system during that time have included local maintenance of rip rap levee toe protection, repairs of local areas of sloughing and construction of seepage berms on the land side of the RD 17 levees at several locations.

Hydraulic Analysis

The purpose of the hydraulic analysis was to estimate the distribution of peak discharges at the Old River/San Joaquin River bifurcation and document changes that would occur to the river hydraulics downstream of the bifurcation if levee setback alternatives were constructed. To conduct the analysis effectively, two programs were used to model the fluvial hydraulics of the system. The first was the Hydrologic Engineering Center – River Analysis System (HEC-RAS) program developed by the Corps, and the second was the finite element analysis program Flo-2D. A 19 day, 100 year input hydrograph with a peak flow of 48,284 cfs at the upstream boundary of the setback alignment was used as the basis for the hydraulic analysis.

Results

Tables 3 and 4 below contain both the measured flow data and the calculated flow data, respectively. The downstream and upstream indicators refer to the reach location of the San Joaquin River relative to the Old River bifurcation.

Table 3: Empirical Peak Flow Rates (100-year recurrence interval hydrograph)

		Measured 100 Year Peak Flow Rates
Corps Data	Reach 26 (San Joaquin upstream)	48,284
	Reach 31 (Old River)	34,850
	Reach 30 (San Joaquin downstream)	12,051

Table 4: Calculated Peak Flow Rates (100-year recurrence interval hydrograph)

		MODELED PEAK FLOWS (cfs)		
		Existing Levee Conditions	Proposed Levee Conditions	
			SCENARIO 1	SCENARIO 2
Flo2D	Reach 26 (San Joaquin - upstream)	48,284	48,284	48,284
	Reach 31 (Old River)	35,208	31,751	31,857
	Reach 30 (San Joaquin - downstream)	12,969	16,546	16,441
HEC-RAS	Reach 26 (San Joaquin - upstream)	48,284	48,284	48,284
	Reach 31 (Old River)	33,047	30,231	31,280
	Reach 30 (San Joaquin downstream)	15,233	18,033	16,988

Conclusion:
Based on the results of the hydraulic modeling, it Scenarios 1 and 2 increase peak flows in the San Joaquin river channel downstream of the Old River bifurcation by approximately 3000 cubic feet per second. The results are summarized in the table below.

Table 5: Change in 100-year peak discharge per Scenario.

		Flow change (cfs) Implementation of Scenario 1	Flow change (cfs) Implementation of Scenario 2
Flo2D	Reach 31 (Old River)	-3,457	-3,351
	Reach 30 (San Joaquin – downstream)	3,577	3,472
HEC-RAS	Reach 31 (Old River)	-2,816	-1,767
	Reach 30 (San Joaquin downstream)	2,800	1,755

These increased peak flows would overwhelm the levee system downstream of the bifurcation therefore the set back levee alternatives studied are not considered feasible for implementation.

I. Economic Feasibility

EIP Guideline Criterion 5 - Economic Feasibility of Section I.1.c., requires the Applicant to demonstrate, with supporting documentation, that their proposed Projects are economically feasible. A Project is considered economically feasible when the present value of its total benefits exceeds the present value of the total costs over the life of the Project. RD 17 conducted an Economic Feasibility analysis of both the 100-Year Levee Seepage Area Project and also the 200-Year Area Plan. Both analyses concluded that the projects are economically feasible. The following is a summary of the analyses. A copy of the detailed analyses can be found in Appendix 11.

Study Area & Methodology
The area studied was RD 17 as described earlier. Within RD 17, development is located in the northern most portion of the study area and along the Interstate 5

10. Letter from USACE to USFWS, requesting initiation of formal consultation. March 3, 2017.

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS, SACRAMENTO DISTRICT
1325 J STREET
SACRAMENTO, CALIFORNIA 95814-2922

Environmental Resources Branch

Ms. Maria Rae, Assistant Regional Administrator
National Marine Fisheries Service
650 Capitol Mall, Suite 5-100
Sacramento, California 95814-4700

Dear Ms. Rae:

I am writing to continue informal consultation under Section 7 of the Endangered Species Act, for a combined Department of Army permit application and a Section 408 permission request for Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair Project. We are also requesting to consult with your agency under the Magnusson-Stevens Fishery Conservation and Management Act (MSA) for Pacific Coast Salmon (*Oncorhynchus* spp.) essential fish habitat (EFH). The project is proposed by RD 17, and is located along the San Joaquin River in RD 17 in San Joaquin County, California. A copy of the February 2017, "Phase 3 – RD 17 Levee Seepage Repair Project, Final Biological Assessment" (BA), prepared by GEI, is enclosed.

The Sacramento District (Corps) originally requested to informally consult in a letter dated March, 27, 2015. The National Marine Fisheries Service (NMFS) responded in a letter, dated July 7, 2015, and requested additional information (Appendix D-3). Our specific responses to each element of the information request are provided in Appendix D-4 of the enclosed biological assessment (BA). This information has also been incorporated into the main body of the BA, as appropriate. The BA also includes an updated description of the proposed action.

Based on the available information, we have determined that the action may affect, but is not likely to adversely affect, Federally listed Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*), Central Valley spring-run Chinook salmon ESU (*Oncorhynchus tshawytscha*), Sacramento River winter-run Chinook salmon ESU (*Oncorhynchus tshawytscha*) and the Southern DPS of North American green sturgeon (*Acipenser medirostris*). The proposed action will not result in destruction or adverse modification of designated critical habitat for any of these species and will not adversely affect designated Chinook salmon EFH. We request your written concurrence with our determinations. If new information becomes available indicating that other listed species or critical habitat may be affected, we will follow the procedures under 50 CFR 402.16, Reinitiation of Consultation.

The RD 17 Levee Seepage Repair Project is a program of levee repairs and improvements for 19 miles of levee along the San Joaquin River and Walthall Slough. This program is being implemented in three phases. The overall purpose of the program is to repair levee geometry to meet Federal and State levee standards, and to improve levee performance to better address under- and through-seepage. Most improvements are on, or landward of, the existing levee. The Phase 1 Project was completed in 2009. The Phase 2 Project was completed in summer 2010. The Phase 3 Project is the subject of this consultation.

To implement the Phase 3 Project, RD 17, through the Central Valley Flood Protection Board, is requesting permission from the U.S. Army Corps of Engineers pursuant to Section 14 of the Rivers and Harbors Act of 1899 (title 33 of the United States Code [USC], Section 408 [33 USC 408], referred to as Section 408, for alterations of Federal projects. RD 17 is also seeking a permit under Section 404 of the Clean Water Act (33 USC 1344) for placement of fill into jurisdictional waters of the United States.

The following information is provided to your office to initiate consultation:

A description of the action to be considered: The proposed levee modifications would involve: (1) installing approximately 3.3 miles of soil and bentonite cutoff walls; (2) constructing 0.64 miles of seepage berms; (3) constructing a 1,240 foot-long setback levee to restore at least 4.52 acres of floodplain; and (4) filling 0.77 acres of Waters of the United States, including wetlands, and other associated upland fill. A more detailed description of the proposed action is provided in Table 2 ("Summary of Major Activities Proposed for Each Element; Preferred Alternative") of the Enclosed BA. This work would eliminate or reduce levee deficiencies, including through- and under-seepage, slope stability, erosion and encroachments, within the construction footprint.

Details of RD 17's preferred alternative are provided in the enclosed BA and accompanying CD. The CD contains the 65 percent engineering designs plans for the preferred alternative. RD 17 proposes to construct the project over two construction seasons.

A description of the specific area that may be affected by the action: The work proposed as part of the Phase 3 Project would involve modifying approximately 5.3 miles of the Federal levee on the east bank of the San Joaquin River to reduce the potential for flooding, flood damage, and public risk in RD 17. Exhibit 2 of the enclosed BA shows the location of the proposed Phase 3 work. It also depicts levee work completed as part of the earlier Phase 1 and Phase 2 projects. Site specific details are shown in the enclosed BA in Exhibits 4a through 4c, and 13a through 13c.

A description of any listed species or critical habitat that may be affected by the action: We have determined that the proposed action may affect, but is not likely to adversely affect, Central Valley steelhead DPS, Central Valley spring-run Chinook salmon ESU, and the Southern DPS of North American green sturgeon.

A description of the manner in which the action may affect any listed species or critical habitat and analysis of any cumulative impacts: The Phase 3 Project would involve constructing several cutoff walls, which would entail degrading the top one-third to one-half of the levee. The degrade would begin at the waterside edge of the levee crown and would be accomplished without disturbing the waterside levee face. Exhibit 8 in the enclosed BA shows this measure. Implementing cutoff walls as part of the Phase 3 Project would disturb soils along the top of the levee which, through wind and water erosion, could enter the San Joaquin River. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately be pumped into the San

Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff. Through the implementation of water quality best management practices, including a Stormwater Pollution Prevention Plan, the proposed conservation measures (see pages 30 and 31 of the enclosed BA), would avoid direct and indirect take of fish during construction.

A setback levee would be constructed along one segment and the existing project levee would be modified to allow high water to flow onto the floodplain between the existing levee and the new setback levee. Fish and other aquatic organisms would likely flow onto the floodplain. The offset area would be contoured to drain back into the San Joaquin River as the water recedes in a manner that would avoid trapping fish landward of the existing levee. This is described in greater detail on page 23 of the enclosed BA.

Relevant reports including any environmental impact statement, environmental assessment, or biological assessment prepared: A copy of the February 2017, "Phase 3 – RD 17 Levee Seepage Repair Project, Final Biological Assessment" (BA), prepared by GEI, is enclosed.

Any other relevant available information on the action, the listed species, or critical habitat: See the enclosed BA.

This constitutes the best scientific and commercial data available. If you need additional information, or determine that conditioning the permit and letter of permission or modifying the project would preclude the need for formal consultation, please contact us immediately.

A copy of this letter, with the enclosure, will be furnished to Mr. Howard Brown, National Marine Fisheries Service, 650 Capitol Mall, Suite 5-100, Sacramento, California 95814-4700. Copies of the letter will also be furnished: to Dr. Steve Schoenberg, U.S. Fish and Wildlife Service, 2800 Cottage Way, Suite W-2605, Sacramento, CA 95825-1846; Mr. Dante Nomellini, c/o Nomellini, Grilli & McDaniel, P.O. Box 1416, Stockton, CA 95201; Mr. Henry Long, President, Reclamation District No. 17, P.O. Box 1461, Stockton, CA 95201; and Dr. Andrea Shephard, GEI Consulting, Inc. 2868 Prospect Park Drive, Suite 400, Rancho Cordova, CA 95670.

If you have any questions, please contact Ms. Tanis Toland, Environmental Manager, at (916) 557-6717 or by email at Tanis.J.Toland@usace.army.mil.

Sincerely,

Mark T. Ziminske

INTRODUCTION

The purpose of this Biological Assessment (BA) is to review Phase 3 of the Reclamation District No. 17 (RD 17) Levee Seepage Repair Project (LSRP) (Phase 3 Repair Project), including the components of the 2017 Emergency Response Construction Project (collectively "the proposed action"), in sufficient detail to determine the extent to which the proposed action may affect any of the federally listed species described below under "Species Considered." (See "Project Background and History" below for a brief summary of Phase 1 and Phase 2.)

RD 17, which is located in south-central San Joaquin County, California (**Exhibit 1**; see **Appendix A** for all exhibits), is responsible for maintaining 19 miles of levees along Walthall Slough, the San Joaquin River, and French Camp Slough, as well as the dryland levee along the southern boundary of Manteca. For discussion purposes, the RD 17 levees have been divided into 11 distinct "reaches," identified by Roman numerals (i.e., I, II, III…, XI), and subdivided further into 28 "elements," identified by the reach number followed by a lowercase letter and, where needed to further distinguish elements, an Arabic numeral (e.g., Ia, IIa, IIb, …, Va, VIa.1, VIa.2, VIa.4, …, VIe, VIIa, VIIb, …, VIIg…,XIa) (**Exhibit 2**).

This BA does not address the dryland levee (Reaches VIII – XI) because it is not a USACE flood risk management project, and therefore is not subject to Section 408 authorization. The dryland levee is an overland earthen berm, north and east of the San Joaquin River. Under almost all conditions, water does not come in contact with the dryland levee. It only functions as a flood risk management feature if water from the San Joaquin River or Walthall Slough leaves the banks of these waterways and inundates lands north and east, toward Manteca. The dryland levee then acts as an elevated earthen feature that prevents these flood waters from moving farther north. Suitable habitat for federally listed species does not occur along the dryland levee.

This BA has been prepared in accordance with requirements set forth under Section 7 of the federal Endangered Species Act (ESA) (16 United States Code [USC] 1536[c]). It supports formal consultation with the U.S. Fish and Wildlife Service (USFWS) and informal consultation with the National Marine Fisheries Service (NMFS) on the effects of the Phase 3 Repair Project on federally listed species and designated critical habitat. This BA also supports consultation with NMFS for project effects on Pacific Coast Salmon (*Oncorhynchus* spp.) essential fish habitat (EFH), as required by the Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801). (See the "Essential Fish Habitat Assessment" section below.)

Section 7(a)(2) of the ESA directs federal agencies to ensure that their activities are not likely to jeopardize the continued existence of any listed species, or to result in the destruction or adverse modification of critical habitat. This section of the ESA also requires agencies with regulatory authority over listed species to issue biological opinions evaluating the direct and indirect effects of federal actions, and actions that are interrelated or interdependent with the federal action. The biological opinions must determine whether the actions being evaluated may appreciably reduce the listed species' likelihood of surviving or recovering in the wild by reducing their productivity, numbers, or distribution.

To implement the Phase 3 Repair Project, RD 17 is requesting permission from the U.S. Army Corps of Engineers (USACE) for:

- alteration of federal project levees, pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408, referred to in this BA as "Section 408"); and
- placement of fill in jurisdictional waters of the United States, pursuant to Section 404 of the Clean Water Act (33 USC 1344, referred to in this BA as "Section 404").

All Phase 3 Repair Project work occurring on the water side of the levee would be above the high tide line (HTL). Therefore, no additional authorizations under Section 10 of the Rivers and Harbors Act of 1899 are required.

On April 6, 2017, the USACE authorized (SPK-2009-001466) the discharge of fill into waters of the United States at elements Ib, Ie, and IVa, under Regional General Permit No. 8 (Emergency Actions). The 2017 Emergency Response Construction Project was implemented in elements Ia, Ib, Ie, IIIb, IVa, Va, VIa.1, VIcde, and VIIb in February 2017. The majority of the 2017 Emergency Response Construction Project actions were already planned under the Phase 3 Repair Project; however, one component (i.e., a seepage berm) within elements Va and VIa.1 was not part of the actions planned specifically within these elements.

These 2017 Emergency Response Construction Project and the Phase 3 Repair Project activities are described in more detail under "Description of the Proposed Action." This BA analyzes direct, indirect, interrelated/ interdependent, and cumulative effects of the proposed action on federally listed species.

SPECIES CONSIDERED

This document considers species that have been termed “threatened” or “endangered” under the jurisdiction of USFWS and NMFS. On February 27, 2014, biologists consulted the online database maintained by USFWS’s Sacramento Office to conduct a query of the Lathrop (462D) and West Sacramento (462A) 7.5-minute quadrangles (USFWS 2014) (**Appendix B**). Another query of the USFWS database was conducted on April 18, 2016 (USFWS 2016) (**Appendix B**), and the information in this BA was updated, based on those results. Using the California Department of Fish and Wildlife’s (CDFW’s) California Natural Diversity Database (CNDDB) (CDFW 2014) and the California Native Plant Society’s database of rare and endangered plant species (CNPS 2014), biologists also conducted a query of the topographic quadrangles in which the action area occurs (Lathrop and Stockton West) and the surrounding quadrangles; these database queries were conducted on February 27, 2014, and March 3, 2014, respectively (**Appendix B**). This query identified all listed species in the area surrounding the action area, which is defined here in accordance with ESA guidelines as “all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action” (50 Code of Federal Regulations [CFR] 402.02).

Based on these database queries and the biologists’ familiarity with local flora and fauna, 21 plant and wildlife species that are federally listed as endangered or threatened, or are federally proposed for listing were considered as part of this BA (**Table 1**).

The following federally proposed and federally listed species are known to occur or have the potential to occur in the Phase 3 Repair Project area (USFWS 2014, 2016):

- valley elderberry longhorn beetle (VELB) (*Desmocerus californicus dimorphus*),
- riparian brush rabbit (*Sylvilagus bachmani riparius*),
- delta smelt (*Hypomesus transpacificus*),
- Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*),
- longfin smelt (*Spirinchus thaleichthys*),
- Sacramento River winter-run Chinook salmon evolutionarily significant unit (ESU) (*O. tshawytscha*),
- Central Valley spring-run Chinook salmon ESU (*O. tshawytscha*), and
- the Southern DPS of North American green sturgeon (*Acipenser medirostris*).

The other federally listed species shown in Table 1 were eliminated from further consideration; they are not likely to occur in the Phase 3 Repair Project area because of a lack of suitable habitat, local range restrictions, regional extirpations, or lack of connectivity between areas of suitable or occupied habitat, or because the action area is located outside the extant range of the species (see “Action Area” section below). The USFWS and NMFS-regulated species with the potential to occur on-site are discussed in more detail in this BA.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
Plants			
Large-flowered fiddleneck *Amsinckia grandiflora*	Endangered[2] SJMSCP-covered[4]	Annual herb with bright orange, trumpet-shaped flowers that bloom in late spring. Historically found on north-facing slopes in the upper elevations of grasslands near the blue oak belt in Contra Costa, Alameda, and San Joaquin counties.	No potential to occur. No suitable habitat is present in the action area.[3]
Palmate-bracted bird's-beak *Cordylanthus palmatus*	Endangered[2]	Annual herb that blooms from late spring through summer. Grows on seasonally flooded, saline-alkali soils in lowland plains and basins at elevations of less than 500 feet. Known from scattered locations in Sacramento and San Joaquin valleys; however, unlikely to occur in San Joaquin County because of lack of alkali habitat.	No potential to occur. No suitable habitat is present in the action area.[3]
Invertebrates			
Conservancy fairy shrimp *Branchinecta conservatio*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	Threatened SJMSCP-covered[4]	Inhabits elderberry shrubs, primarily in riparian woodland and scrub habitat.	Could occur; elderberry shrubs present occasionally along the San Joaquin River on the waterside and landside of the Phase 3 Repair Project levee; however, no evidence of beetle exit holes was observed in these shrubs.
Vernal pool fairy shrimp *Branchinecta lynchii*	Threatened SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Vernal pool tadpole shrimp *Lepidurus packardi*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Fish			
Central Valley steelhead *Oncorhynchus mykiss*	Threatened	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Designated critical habitat is in the action area.
Central Valley fall/late fall–run Chinook salmon *Oncorhynchus tshawytscha*	Species of Concern[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Essential fish habitat for this species is in the Phase 3 Repair Project area.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
Delta smelt *Hypomesus transpacificus*	Threatened[2] SJMSCP-covered[4, 5]	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears seasonally in inundated floodplains, tidal marsh, and the Delta.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin rivers, tributaries, and Delta. Although no spawning habitat is in the action area, delta smelt has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Longfin smelt *Spirinchus thaleichthys*	Candidate/ Proposed Threatened[2] SJMSCP-covered[4, 5]	Pelagic estuarine. Ranges from the Delta in California northward to the Cook Inlet in Alaska.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin rivers, tributaries, and the Delta. Although no spawning habitat is in the action area, longfin smelt has potential to occur in the San Joaquin River in the action area.[3]
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	Endangered[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. No spawning habitat is in the action area. Unlikely to occur in the San Joaquin River in the action area[3]; however, occasional adult and/or juvenile strays may be present.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	Threatened[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. Currently unlikely to occur in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. However, occasional adult and/or juvenile strays may be present. The SJRPP[6] includes the reintroduction of this species (an experimental population) to the San Joaquin River.
Green sturgeon *Acipenser medirostris*	Threatened SJMSCP-covered[4, 5]	Requires seasonally inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Amphibians and Reptiles			
California red-legged frog *Rana draytonii (=R. aurora draytonii)*	Threatened SJMSCP-covered[4]	Prefers semi-permanent and permanent stream pools, ponds, and creeks with emergent riparian vegetation and typically without predatory fish. Requires adequate hibernacula, such as small-mammal burrows and moist leaf litter.	No potential to occur. Potential aquatic habitat in the Phase 3 Repair Project area is limited to one constructed pond, likely with predatory fish, but the action area is outside the species' extant range.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
California tiger salamander *Ambystoma californiense*	Threatened[2] SJMSCP-covered[4]	In winter, breeds in vernal pools and stock ponds that are fish-free and inundated for a minimum of 12 weeks. In summer, aestivates in rodent borrows in grassland habitat.	Unlikely to occur. Potential aquatic habitat in the Phase 3 Repair Project area is limited to one constructed pond, likely with predatory fish; a small area of freshwater marsh in element Ib[7]; and agricultural ditches. Much of the action area consists of urban and agricultural land that is not suitable as potential upland habitat. A 1996 CNDDB record documents California tiger salamander adjacent to State Route 120 in roadside seasonal wetland; however, it is approximately 2 miles east of the San Joaquin River and geographically isolated.
Giant garter snake *Thamnophis gigas*	Threatened[2] SJMSCP-covered[4]	Streams, sloughs, ponds, and irrigation/drainage ditches; also requires upland refugia not subject to flooding during the snake's inactive season.	Unlikely to occur. Although potential habitat for this species is present in the Phase 3 Repair Project area, none of it is suitable. The only documented occurrences of giant garter snake are separated from the Phase 3 Repair Project area by extensive urbanized development (City of Stockton) and large rivers that do not provide suitable habitat and are a greater distance than the species is known to disperse. For additional information that summarizes the rationale that supports the "unlikely to occur" determination for this species in the Phase 3 Repair Project area, refer to **Appendix C** in this document.
Birds			
Least Bell's vireo *Vireo bellii pusillus*	Endangered[2]	Nests in riparian habitat adjacent to riverine and freshwater marsh.	Unlikely to occur. Although suitable habitat is present, the last recorded observation of this species in the action area was in 1878, with no extant occurrences.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	Threatened SJMSCP-covered[4]	Insect-feeder that forages in dense riparian oak forest canopy along major rivers. Species is considered extirpated from San Joaquin County.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Repair Project area, the action area is outside the species' extant range.
Mammals			
San Joaquin kit fox *Vulpes macrotis mutica*	Endangered SJMSCP-covered[4]	Annual grassland or grassy open stages with scattered shrubby vegetation; needs loose-textured sandy soils for burrowing, and suitable prey base.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Repair Project area, the action area is outside the species' extant range.
Riparian brush rabbit *Sylvilagus bachmani riparius*	Endangered[2] SJMSCP-covered[4, 5]	Inhabits riparian oak forest with dense understory of wild roses, grapes, and blackberries; small home ranges, seldom moving more than a few feet from cover, avoiding large openings in shrub cover and frequenting small clearings.	Known to occur. Occupied riparian habitat is present on the waterside of elements IIIa and IIIb, and suitable habitat is present immediately adjacent to the project area in several elements; the species also is known to occur on an oxbow between elements VIa.1 and VIa.4[7] and in waterside habitat between elements IIab and IIIa.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River**[1]
Riparian (=San Joaquin Valley) woodrat *Neotoma fuscipes riparia*	Endangered SJMSCP-covered[4]	Requires healthy riparian forests, where it nests in cavities in trees, snags, or logs, spaces in talus, or lodges built of downed woody materials. Known to exist in and immediately adjacent to Caswell Memorial State Park, along the Stanislaus River in San Joaquin County.	No potential to occur. The action area is outside the species' extant range.

Notes: CNDDB = California Natural Diversity Database; Delta = Sacramento–San Joaquin Delta; Phase 3 Repair Project = Phase 3 of the proposed Reclamation District No. 17 Levee Seepage Repair Project; SJMSCP = San Joaquin Multi-Species Habitat Conservation and Open Space Plan; SJRRP = San Joaquin River Restoration Program

1 **Potential for Occurrence Definitions:**

No potential to occur; Suitable habitat is not present in the Phase 3 Repair Project area and/or the Phase 3 Repair Project area is not within the historical or current range of the species.

Unlikely to occur: Potential habitat present, but species unlikely to be present in the Phase 3 Repair Project area because of current status of the species, a very restricted distribution, and/or essential habitat components are not present.

Could occur: Suitable habitat is available in the Phase 3 Repair Project area; however, few or no other indicators show that the species may be present.

Likely to occur: Habitat conditions, behavior of the species, known occurrences in the Phase 3 Repair Project area, or other factors indicate a relatively high likelihood that the species would occur in the Phase 3 Repair Project area.

Known to occur: The species, or evidence of its presence, was observed in the Phase 3 Repair Project area during reconnaissance-level surveys or was reported by others.

2 These species have a similar status listing under the California Endangered Species Act, except for delta smelt and western yellow-billed cuckoo, which are both State-listed as endangered, and longfin smelt and San Joaquin kit fox, which are both State-listed as threatened.

3 Action Area: The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project. Areas downstream from the Phase 3 Repair Project area may also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions.

4 SJMSCP-covered: These species are covered under the SJMSCP (San Joaquin County 2000).

5 SJMSCP-covered with limitations: The SJMSCP does not cover the conversion of occupied riparian brush rabbit habitat, limits the amount of delta smelt habitat, and does not authorize take of green sturgeon.

6 See "San Joaquin River" subsection under "Environmental Baseline" section below, for more information.

7 Elements: The RD 17 levees have been divided into seven distinct "reaches" identified by Roman numerals (i.e., I, II, III), and subdivided further into 19 "elements," identified by the reach number followed by a lowercase letter and, in some cases, an Arabic numeral (e.g., Ia, IIa, Va, VIa.1…); see **Exhibit 2**.

Sources: CDFW 2014; CNPS 2014; USFWS 2014, 2016; data compiled by AECOM in 2014 and updated by GEI Consultants in 2016

SPECIES HABITAT AND POTENTIAL FOR OCCURRENCE IN THE AREA

The following is a summary of relevant habitat conditions in the action area for species that could occur, are likely to occur, or are known to occur in the Phase 3 Repair Project area. Full species accounts for federally listed species addressed in this BA are presented in the "Species Accounts" section.

- **Valley elderberry longhorn beetle:** Elderberry shrubs provide habitat for VELB. Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Repair Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Repair Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

- **Riparian brush rabbit:** Trapping conducted in February 2003 and February 2004 detected occurrences of riparian brush rabbit near the Phase 3 Repair Project area in waterside riparian habitat adjacent to elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1 and VIa.4 (CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004). The waterside habitat along elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The trapping locations between elements IIab and IIIa are dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The trapping locations between elements VIa.1 and VIa.4 are on an oxbow with dense riparian vegetation. Similar riparian habitat is present adjacent to the waterside of elements IIab, IVc, and Va. North of element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, or isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species.

- **Delta smelt:** Delta smelt are found from Suisun Bay upstream through the Sacramento–San Joaquin Delta (Delta). Delta smelt disperse widely into freshwater in late fall and winter as the spawning period approaches, and may move as far upstream as Mossdale on the San Joaquin River (Bennett 2005). Therefore, this species has the potential to occur in the Phase 3 Repair Project area.

- **Longfin smelt:** Longfin smelt occur in the Delta and tidally influenced segments of the Sacramento and San Joaquin rivers. The occurrence of longfin smelt in the San Joaquin River is rare, but it does occur on occasion when river salinity extends farther upstream, either because of Delta pumping or because of drought. Therefore, this species has the potential to occur in the Phase 3 Repair Project area.

- **Anadromous salmonids:** The action area (see "Action Area" section below) does not provide suitable spawning habitat for salmonids because it lacks the cold freshwater and gravel substrate characteristic of salmonid spawning areas in upper river basins. However, adult and juvenile Central Valley fall-run Chinook salmon and Central Valley steelhead could occur in the action area during migrations along the San Joaquin River and its tributaries. Winter-run and spring-run Chinook salmon are known to occur only in the Sacramento River and its tributaries (Moyle 2002). Because the action area is along the San Joaquin River, several miles upstream from its confluence with the Sacramento River, adult migrants along the Sacramento River are not expected to move into the action area. However, with implementation of the San Joaquin River Restoration Project (SJRRP) (see "San Joaquin River" subsection under "Environmental Baseline" below), an experimental population of spring-run Chinook salmon are being reintroduced to the San Joaquin River, initiated in 2014, to achieve one of the goals of the SJRRP, which is "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River…including naturally reproducing and self-sustaining populations of salmon and other fish" (NMFS 2013).

- **Green sturgeon:** Green sturgeon is known to occur in the San Joaquin River and Delta, and therefore, has the potential to occur in the lower San Joaquin River in the Phase 3 Repair Project area (Moyle 2002). Currently, green sturgeon spawning in the San Joaquin River is not documented.

CRITICAL HABITAT

"Critical habitat" is defined in Section 3(5)A of the ESA as the specific areas in the geographical area occupied by the species where physical or biological features are found that are essential to the conservation of the species and that may require special management considerations or protection. Specific areas outside the geographical area occupied by the species also may be included in critical-habitat designations, based on a determination that such areas are essential for conservation of the species.

The proposed action addressed in this BA would fall within designated critical habitat for delta smelt, which was designated on December 19, 1994 (59 Federal Register [FR] 65256). Critical habitat is designated to include most tidally influenced areas of the Delta.

The proposed action addressed in this BA would fall within designated critical habitat for the Central Valley steelhead DPS. Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin river basins, including the segment of the San Joaquin River in the action area (see "Action Area" section below).

The proposed action addressed in this BA would fall within designated critical habitat for the Southern DPS of North American green sturgeon. Critical habitat for green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

The action area is not within designated critical habitat for the remaining species listed in **Table 1,** for which such a designation has been made: large-flowered fiddleneck, Conservancy fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, VELB, Sacramento River winter-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, California red-legged frog, California tiger salamander, and least Bell's vireo. Critical habitat has not been designated for palmate-bracted bird's-beak, longfin smelt, Central Valley fall/late fall–run Chinook salmon ESU, giant garter snake, western yellow-billed cuckoo, San Joaquin kit fox, riparian brush rabbit, or riparian woodrat.

SAN JOAQUIN MULTI-SPECIES CONSERVATION PLAN

All of the above species, except the anadromous salmonid fish species, are covered on some level under the San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) (San Joaquin County 2000). The SJMSCP was developed to avoid, minimize, and mitigate impacts on plant and wildlife habitat projected to occur in San Joaquin County between 2001 and 2051, resulting from the anticipated conversion of open space land to non–open space uses. Ninety-seven species are covered by the SJMSCP. The plan is intended to provide comprehensive mitigation, in accordance with local, State, and federal regulations, for impacts of SJMSCP-permitted activities on these species. USFWS and CDFW participated in development of the SJMSCP, approved the mitigation, and agreed to issue incidental take permits for species and activities covered by the SJMSCP.

The geographic area covered in the SJMSCP extends up to the landside levee crown of the San Joaquin River levee and includes the Phase 3 Repair Project area. However, the SJMSCP does not cover federal flood risk management projects or activities that involve tidally jurisdictional wetlands or other waters of the United States, and thus the Phase 3 Repair Project would not be a covered activity under the SJMSCP. The SJMSCP outlines a mechanism by which a federal flood risk management project, such as the Phase 3 Repair Project, could obtain take coverage under the SJMSCP (see Section 8.2.3 of the SJMSCP). However, because the SJMSCP does not cover special-status fish, the conversion of riparian brush rabbit habitat, or impacts on other species on the waterside of the levee, RD 17 and USACE would not rely on the SJMSCP to assess and offset Phase 3 Repair Project effects on federally listed and State-listed species. Rather, through this BA and the associated Section 7 consultations with USFWS and NMFS, RD 17 and USACE would seek take authorization for Phase 3 Repair Project activities. Species listed under the California Endangered Species Act that also are covered species under the SJMSCP would be evaluated through coordination with CDFW.

CONSULTATION TO DATE

The list below summarizes correspondence, meetings, and discussions between regulatory agencies, RD 17, and consultants that relate to potential effects of the Phase 3 Repair Project on species addressed in this document. The most recent consultation is listed first.

4/6/2017 Authorization from USACE issued to RD 17 for discharge of fill into waters of the United States for the 2017 Emergency Response Construction Project (SPK-2009-001466) under Regional General Permit No. 8 (Emergency Actions).

4/18/2016 Letter from USFWS to GEI Consultants regarding the Species List for Phase 3–RD 17 Levee Seepage Repair Project (**Appendix B**)

10/2/2015 Letter from USFWS to USACE requesting additional information on the RD 17 Phase 3 Repair Project BA (**Appendix D-5**). A letter response to comments was completed by GEI Consultants and AECOM, on behalf of RD 17 (**Appendix D-6**).

7/7/2015 Letter from NMFS to USACE requesting additional information on the RD 17 Phase 3 Repair Project BA (**Appendix D-3**). A letter response to comments was completed by GEI Consultants and AECOM, on behalf of RD 17 (**Appendix D-4**).

2/27/15 Letter from USACE to NMFS transmitting the BA and requesting informal consultation.

2/27/15 Letter from USACE to USFWS transmitting the BA and requesting to initiate formal Section 7 consultation.

2/27/14 Letter from USFWS to AECOM regarding the Species List for RD 17 100-Year Levee Seepage Area Project[1] (**Appendix B**)

3/1/11 Tour of proposed action area with representatives from AECOM, USACE, USFWS, NMFS, and CDFW.

1/24/11 Meeting with representatives of USFWS and AECOM to discuss project permitting coordination, potential effects of the project on federally listed species, and development of a conservation strategy.

12/9/10 Meeting with representatives of CDFW and AECOM to discuss project permitting coordination, the potential effects of the project on State-listed species, use of the SJMSCP, and development of a conservation strategy.

8/24/10 Meeting with representatives of USACE, USFWS, NMFS, and AECOM to discuss the potential effects of the project on listed species and development of a conservation strategy.

6/11/10 Letter from NMFS to AECOM, responding to May 14, 2010, letter requesting technical assistance (**Appendix D-2**).

5/14/10 Letter from AECOM, prepared on behalf of RD 17, to USFWS and NMFS requesting informal technical assistance in evaluating the potential effects on listed species that could result from implementing USACE vegetation management standards, and in developing a conservation strategy to adequately offset the potential loss of habitat. Copies of the wetland delineation report and maps were provided with the letter (**Appendix D-1**).

---

1 "RD 17 100-Year Levee Seepage Area Project" is a reference to the RD 17 Levee Seepage Repair Project. This former name was used in documents published before preparation of the Final Environmental Impact Statement for Phase 3 of the RD 17 Levee Seepage Repair Project.

DESCRIPTION OF THE PROPOSED ACTION

U.S. ARMY CORPS OF ENGINEERS ACTION

RD 17, in cooperation with the California Department of Water Resources (DWR) and the Central Valley Flood Protection Board (CVFPB), is the local project sponsor for the Phase 3 Repair Project. RD 17 has requested permission from the CVFPB and USACE to alter segments of the San Joaquin River Levee System, which is a federal project levee. The proposed action for USACE is to make a permit decision on the Phase 3 Repair Project under the authority of Clean Water Act Section 404 and a permission decision under Section 408 of Title 33 USC. Under Section 408, USACE may allow the permanent use or occupancy of a USACE flood risk management project with approval by the Secretary of the Army on recommendation of the Chief of Engineers, provided that such use or occupancy would not be injurious to the public interest. USACE has determined that a Section 408 decision would be required for repair of seepage deficiencies to federal project levees. The activities requiring Section 408 and/or 404 authorizations, described in more detail below, include proposed alterations/repairs to USACE flood risk management facilities and fill of jurisdictional waters during earth-moving activities for levee construction. Activities for the Phase 3 Repair Project would be processed through an encroachment permit with the CVFPB. USACE would conduct a technical engineering review as part of the evaluation of the CVFPB's request to modify the Federal flood risk management project, in accordance with USACE regulations under 33 CFR 408.

PROJECT LOCATION

RD 17 is located in south-central San Joaquin County, California, in the center of the California Central Valley, at the north end of the San Joaquin River Basin, and within the far southeast limit of the Delta (see **Exhibit 1**). The boundaries of RD 17 are marked by French Camp Slough on the north, approximately 3 miles southwest of the central business district of the city of Stockton; the San Joaquin River on the west; Walthall Slough on the south (just below State Route 120); and Airport Way/McKinley Avenue on the east, just outside the city of Manteca. RD 17 is responsible for maintaining the levees along the east bank of the San Joaquin River from just south of Mathews Road to Walthall Slough, the levees along the north bank of Walthall Slough, and the dryland levee out to approximately South Airport Way (see **Exhibit 2**).

The proposed action is located along specific reaches of the RD 17 levees, as depicted in **Exhibit 2**. The Phase 3 Repair Project's landside levee improvements would include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system.

PROJECT BACKGROUND AND PURPOSE

PROJECT BACKGROUND AND HISTORY

The RD 17 system for reducing the risk of flood damage, like other flood protection systems in the San Joaquin Valley, initially was designed to facilitate agricultural development on the extensive valley floodplains and to support river navigation. Levees set closely along the rivers were designed to contain flows generated by common floods, and bypasses were constructed to carry overflows generated by large floods. The close-set levees ensured that water velocities would help scour the river bottom and move sediment through the system, reducing dredging costs for sustaining navigation. Starting in about 1863, RD 17 undertook the maintenance and reconstruction of the levee system.

Some of the levees in the Delta are considered "federal project levees." These levees were constructed or reconstructed (e.g., existing or damaged farm levees were improved) by USACE and are intended to meet federal standards. Construction of the federal levee system that encompasses the current RD 17 levees along Walthall

Slough, the San Joaquin River, and French Camp Slough began in 1944 and was completed in 1963. The levee system has since been upgraded substantially to meet Federal Emergency Management Agency (FEMA) requirements for flood protection during a 100-year flood event (flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability) [AEP]). In 1990, after extensive analysis, the RD 17 levees were accredited by FEMA as meeting the 100-year requirements for urban development.

During a high-water event on the San Joaquin River in January 1997, seepage and boils occurred at several locations along the RD 17 levees. USACE, DWR, and RD 17 successfully contained the seepage and boils, and the levees did not break. After the 1997 event, USACE, the CVFPB, and RD 17 funded a project, the Reconstruction of the California Central Valley Levees San Joaquin Basin #4, Reclamation District #17 Project, to repair the seepage and boil areas. The project was designed and constructed by USACE, and work was completed in 2003.

After reviewing the data supporting the 1990 accreditation and subsequent information, FEMA notified RD 17 of its intention to confirm full accreditation of the RD 17 levees as meeting FEMA's requirements for 100-year flood protection. On June 19, 2007, DWR wrote a letter to the City of Lathrop, with a copy to FEMA, stating that it could not support recertification of the RD 17 levees or the granting of provisional accreditation because of concerns about seepage exit gradients.[2] The basis of DWR's concern was analysis showing seepage exit gradients greater than 0.5, which indicated a higher likelihood of seepage or boils occurring during a high-water event Because of DWR's concern, FEMA then denied full accreditation and instead granted provisional accredited levee (PAL) status to the RD 17 levees. A PAL is a levee that FEMA has previously credited with providing a 100-year flood event level of flood risk reduction (i.e., flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability). In fall 2007, in response to the PAL status, RD 17 initiated a levee seepage repair program and requested funding through DWR's Early Implementation Program.

RD 17 subsequently implemented Phases 1 and 2 of the LSRP. After completion of the Phase 1 and 2 levee repairs, RD 17 submitted a recertification application to FEMA. In September 2010, RD 17 received a response letter declaring that FEMA had accredited the area protected by the RD 17 levee system, including the dryland levee, thereby removing the PAL status.

The Phase 1 Project included construction of two seepage berms, located in elements III and VI of the LSRP (**Exhibit 2**). The project reconstructed and extended the landside levee toe berms with earth and gravel fill, both landward and along the levee toe, to reduce seepage exit gradients. Work areas were designed to avoid any environmental resources of possible significance, including sensitive habitats and listed species. The project was determined to be categorically exempt from the California Environmental Quality Act (CEQA), and no federal authorizations or funding was required for the Phase 1 work; therefore, no National Environmental Policy Act (NEPA) analysis was triggered. The Phase 1 Project work was completed in January 2009.

The Phase 2 Project addressed work needed at nine levee reaches in the LSRP area. At eight of the nine reaches, the project involved constructing drained seepage berms along the landside levee toe. At one site that did not include seepage berm construction, RD 17 acquired an easement on land along the levee toe and performed various maintenance and site cleanup activities. A CEQA initial study/mitigated negative declaration that was completed for the Phase 2 Project concluded that no significant effects would occur on environmental resources after mitigation measures were implemented (RD 17 2009). Potential impacts on biological resources that resulted from Phase 2 Project implementation were mitigated through participation in the SJMSCP. No federal

---

2 "Seepage exit gradient" is an expression in numeric form of the potential for under seepage to exit on the landside of a levee as seepage or a boil. The lower the number used to express seepage exit gradient, the more resistant the system is to seepage or boils; the higher the number, the more likely seepage or boils may occur during a high water event. In formulas for seepage exit gradients, the numerator (top number in a fraction) typically addresses forces that cause or enhance seepage (e.g., water pressure), and the denominator typically addresses forces that resist seepage (e.g., soil resistance to water pressure, depth and weight of soil over the potential seepage area, distance from the levee toe). A lower seepage exit gradient (i.e., more resistance to seepage) is achieved when the numerator (positive seepage forces) is reduced and/or the denominator (resistance to seepage) is increased.

authorizations or funding was required for the Phase 2 work; therefore, no NEPA analysis was triggered. All Phase 2 Project work was completed in summer 2010.

Project Purpose and Objectives

The overall purpose of the Phase 3 Repair Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.3 miles of the approximately 19-mile RD 17 levee system, to reduce the risk of flooding in the RD 17 service area during a 100-year flood event. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation. USACE and RD 17 each view the project purpose from the purview of their respective responsibilities, defined as follows:

USACE's objectives for the Phase 3 Repair Project are to:

- decide whether or not to grant permission for the RD 17 Phase 3 Repair Project to alter the federal project levees within its levee system under Section 408, and
- decide whether or not to issue permits under Section 404.

RD 17's objectives for the proposed Phase 3 Repair Project are to:

- repair seepage deficiencies where needed to meet current USACE seepage criteria standards,
- increase the levee's resistance to under seepage and/or through seepage,
- provide under seepage exit gradients equal to or less than 0.5 at the landside levee toe, and equal to or less than 0.8 at the landside drainage seepage berm at the water surface elevation associated with the design water surface, and
- meet levee geometry requirements of the permitting agencies in the specific areas of repair work.

All Phase 3 Repair Project work would occur on the landside of the existing levee system, or above the HTL on the water side of the levee, therefore, authorization under Section 10 of the Rivers and Harbors Act of 1899 would not be required. Section 404 authorization would be required for some work on the land side of the levee that would affect wetlands or waters of the U.S. USACE verified a wetland delineation that was submitted for the Phase 3 Repair Project on November 3, 2009 (a preliminary jurisdictional determination form was issued by USACE on November 10, 2009; USACE 2009b), and three supplemental wetland delineations were prepared. The first supplemental delineation was submitted on January 22, 2010 (a preliminary jurisdictional determination form was issued by USACE on April 9, 2010; USACE 2010a). The second supplemental wetland delineation was submitted on September 16, 2010 (a preliminary jurisdictional determination form was issued by USACE on October 7, 2010; USACE 2010b). The third supplemental wetland delineation was submitted on April 4, 2014 (a preliminary jurisdictional determination form was issued by USACE on April 7, 2014; USACE 2014a).

Compliance with USACE Vegetation Management Standards

With issuance of Engineering Technical Letter (ETL) 1110-2-571 in 2009,[3] USACE updated its vegetation management standards for levees, requiring the removal of all vegetation, with the exception of perennial grasses, on levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2009a). In September 2011, USACE issued a Draft Environmental Impact Statement/Draft Environmental Impact Report (DEIS/DEIR) for the Phase 3 Repair Project (USACE and RD 17 2011). The September 2011 DEIS/DEIR considered two options for complying with ETL 1110-2-571, as follows:

[3] USACE ETL 1110-2-571 subsequently was replaced by ETL 1110-2-583 on April 30, 2014 (USACE 2014b).

- Full Implementation of USACE ETL 1110-2-571: All vegetation, other than perennial grasses, would be removed from the levee slopes and out 15 feet from the waterside and landside levee toes, or

- Acquisition of a Variance from Full Compliance with USACE ETL 1110-2-571: Permission would be obtained from USACE to retain all vegetation on the lower two-thirds of the waterside levee slope and out 15 feet from the waterside levee toe; all other levee vegetation still would be removed in accordance with USACE policy.

RD17 is no longer considering full compliance with the ETL as an alternative. RD 17 will continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which includes trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). In the Phase 3 Repair Project area, landside vegetation would be removed as previously evaluated in the September 2011 DEIS/DEIR (USACE and RD 17 2011) and as described under the “Additional Project Components” subsection below as well as in the “Direct and Indirect Effects on Species in the Action Area” section of this BA. Long-term vegetation management practices, for both landside and waterside vegetation, would be managed in accordance with the USACE O&M Manual which includes RD 17’s existing practices, as described under the “Additional Project Components” subsection below as well as in the “Direct and Indirect Effects on Species in the Action Area” section of this BA .

DESCRIPTION OF THE PROPOSED PHASE 3 REPAIR PROJECT

This section describes the elements of RD 17’s overall Phase 3 Repair Project; the Emergency Response Construction Project actions, which were authorized under Clean Water Act Section 404 Regional General Permit No. 8, are described under “Description of the 2017 Emergency Response Construction Project Actions” section that follows this section. This includes a description of the levee repair activities and additional project components that are proposed under the Phase 3 Repair Project, as well as the proposed construction schedule and sequencing.

The Phase 3 Repair Project would address the under seepage and/or through seepage concerns raised by DWR and repair and/or remediate levee geometry to USACE design standards along approximately 5.2 miles of the RD 17 levee system, including portions of the San Joaquin River east levee and portions of the levee along the northerly bank of Walthall Slough. Under seepage occurs below the aboveground levee prism and is caused by the buildup of water pressure in the subsurface foundation soils when high-river stages are present on the waterside of the levees. This pressure head causes water to flow through the earthen foundation layers under the levee and exit onto the ground surface on the landside of the levee prism (**Exhibit 3**). Such seepage is not uncommon and does not inherently imply that the levee is failing; however, excessive and uncontrolled under seepage can carry fine-grained material with the water flow that can undermine the levee and lead to levee failure. Through seepage is the movement of water through the levee prism when high-river stage conditions exist on the waterside of the levee (**Exhibit 3**). Depending on the duration of high water and the permeability of the levee embankment soil, seepage may exit onto the landside slope of the levee, thereby negatively affecting the stability of the landside levee slope.

Levee improvements along the USACE project levees would consist primarily of in-place repair/remediation, but would include a single setback levee at element IVc. As summarized in **Table 2** and shown in **Exhibits 4a** through **4c**, the Phase 3 Repair Project’s landside levee improvements would include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system. These levee repair components, as well as additional project components (such as levee geometry corrections and stormwater management), are described in more detail following **Table 2**. The proposed action does not include any work that would raise the existing levee. Limited work would be performed along the waterside of the levee above the HTL in element IVc, where the setback levee would be constructed.

LEVEE REPAIR ACTIVITIES

The Phase 3 Repair Project would include seepage berms, chimney drains, cutoff walls, a setback levee, and a raised landside grade. **Table 2** summarizes the activities proposed for each project element.

Table 2
Summary of Major Activities Proposed for Each Element of the Phase 3 Repair Project

Element	Type of Remediation	Proposed Activities
Ia	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and install a 590-foot-long seepage berm (minimum 65 feet wide) with chimney drain to meet required exit gradients.
Ib	under seepage and through seepage	Fill existing depression to 300 feet from toe of existing levee; place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width; and install a 125-foot-long seepage berm (minimum 60 feet wide) with chimney drain on top of fill to meet required exit gradients.
Ie, IIIb, IVa, and VIIb	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and construct seepage berms with lengths of 500 feet (Ie), 650 feet (IIIb), 450 feet (IVa), and 250 feet (VIIb), and chimney drains to meet required exit gradients. Minimum seepage berm widths would vary (65–105 feet) depending on the element.
IIab	under seepage and through seepage	Install cutoff wall with a length of 2,550 feet to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.
IVc	under seepage and through seepage	Construct 1,100-foot-long setback levee with seepage berm and cutoff wall to meet required exit gradients. Depth of the cutoff wall will be 60 feet. Cutoff wall will involve degrading the top 1/3 to 1/2 of the levee crown and will begin with a 1:1 cut at the waterside crown. Seepage berm would be a minimum of 65 feet wide. Install riprap on waterside of existing levee above the high tide line where it would intersect setback levee. After setback levee is completed, remove 400 linear feet of the existing levee above the high tide line on the downstream side of oxbow. Grade approximately 8 acres of setback area, to drain to the river through the downstream opening in the remnant levee, and restore at least 9.9 acres, and up to 11.5 acres, of riparian scrub and Great Valley oak woodland in the area between the landside toe of the setback levee and the river. For more information about habitat restoration in element IVc, see the Conceptual Mitigation and Monitoring Plan for the Riparian Brush Rabbit in **Appendix E** of this document.
Va and VIa.1	under seepage and through seepage	Where feasible, place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width and install cutoff walls with a length of 9,520 feet to meet required exit gradients. Depth of cutoff walls would vary from 60–85 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Open-cut method would be used for all cutoff walls.
IIIa	through seepage	Place levee fill material along landside of existing levee slopes where feasible to provide minimum 3:1 slopes and 20-foot levee crown widths and install chimney drain in existing 4,750-feet-long seepage berm to meet required exit gradients.
VIa.4	under seepage and through seepage	Install cutoff wall with length of 70 feet to meet required exit gradients. Depth of cutoff wall would vary from 90–100 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside

Table 2 Summary of Major Activities Proposed for Each Element of the Phase 3 Repair Project		
Element	**Type of Remediation**	**Proposed Activities**
		of existing levee slope where feasible to provide minimum 3:1 slope and 26-foot levee crown width.
VIbcde	under seepage and through seepage	Install cutoff wall with length of 2,050 feet of cutoff wall at element VIb, and approximately 650' of chimney drain at elements VIcde, to meet required exit gradients. Depth of cutoff wall would vary from 70–80 feet. Cutoff wall in levee prism would involve both deep slurry mix construction as well as degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Construct new earthen railroad embankment to replace the existing wooden trestle bridge at element VIc.
VIIe	under seepage and through seepage	Install cutoff wall with a length of 2,500 feet to meet required exit gradients. Depth of cutoff wall would vary from 60–120 feet. Deep slurry mixing method would be used. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width. Soil removed during levee degradation would be stockpiled on adjacent RD 17 property and used for rebuilding the levee at these locations or used for fill at other locations in the Phase 3 Repair Project.
VIIg	under seepage and through seepage	Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width, and construct approximately 395' of seepage berm to meet required exit gradients. Minimum seepage berm width would be 65 feet.
Source: Data provided by Kjeldsen, Sinnock & Neudeck, Inc. in 2014, updated 2017		

The respective levee improvement components are described next in more detail.

SEEPAGE BERMS

Reducing the risk of levee failure caused by under seepage and through seepage may be achieved by constructing a drained seepage berm. A drained seepage berm collects and conveys seepage, thereby reducing the flood risk associated with a high-water event. A drained seepage berm is built on the landside of a levee, and consists of layers of sand filter material, drain rock, geosynthetic filter fabric, and a seepage berm soil fill (**Exhibit 5**).

The drained seepage berm reduces flood risk during sustained high-river events by collecting seepage that otherwise would flow onto the landside ground surface at and beyond the levee's landside toe of slope, and then by conveying the seepage away from the levee. The layer of sand filter material placed on the natural ground surface serves to reduce the transmission of fine-grained soils into the drain rock, thereby maintaining the drain rock's ability to be a conductive soil unit that conveys collected seepage. Similarly, the filter fabric that separates the drain rock from the seepage berm fill soil prevents finer soils from migrating into the drain rock unit. The weight of the berm acts as ballast, reducing the potential for detrimental boils and piping.

The design width and height of a seepage berm are dependent on the relative permeability of the underlying soil layers and the amount of pressure head that push water under the levee and through these soils during sustained high-river events. The higher the water pressure head and the more dissimilar the porosity of the underlying soil layers, the wider and/or taller the seepage berm must be to prevent boils and reduce flood risk.

For the Phase 3 Repair Project, drained seepage berm widths of 65–120 feet are expected to be adequate to meet the design criteria in most cases (**Exhibit 5**). However, these types of berms may extend up to 300–400 feet inland from the landside toe of the levee. Seepage berms typically are constructed using select materials excavated from borrow sites or obtained from commercial sources. For the Phase 3 Repair Project, soil material for seepage berms would be purchased from commercial sources. A compacted-surface patrol road would be constructed near the outside edge of the seepage berm (see "Additional Project Components" below).

In urban areas, some seepage berms also would include a toe drain system (element VIIg) to safely collect and discharge the seepage water into an urban storm drainage system. A toe drain pipe is a below-grade, perforated pipe surrounded by a layer of sand and drain rock (**Exhibit 6**). The toe drain pipe is a mechanism to safely collect and convey seepage water away from the levee and seepage berm. If the toe drain pipe is unable to convey the seepage water, the water exits the drained seepage berm through the drain rock at the face of the berm, similar to a nonurban berm.

CHIMNEY DRAINS

A chimney drain is a drainage system that collects seepage waters that are flowing through the aboveground portion of the levee structure. This type of drain is used to collect and convey through seepage. A chimney drain consists of a 1 to 3-foot-thick layer of sand and drain rock. Filter fabric is placed between the soil and rock layer to avoid migration of the soil into the rock, which can clog the rock layer and reduce its ability to carry seepage flows. The chimney drain is placed directly on the landside slope of the levee and tied into an existing or new drained seepage berm at the landside base of the levee (**Exhibit 7**). The chimney drain conveys the through seepage flows to a drained seepage berm, which is located at the landside base of the levee.

Installing a chimney drain in an existing drained seepage berm would include adding the through seepage material on top of the existing seepage berm and tying this material into the existing seepage berm material by removing the seepage berm fill material and physically tying the two drainage rock layers together. When the remediation includes construction of a new drained seepage berm with a chimney drain, the chimney drain would be installed during construction of the drained seepage berm.

CUTOFF WALLS

In selected locations of the Phase 3 Repair Project, cutoff walls would be placed through the levee prism (parallel to the river). Cutoff walls use specialized earthen materials (often bentonite clay, which has low permeability, or a mixture of bentonite and cement). Cutoff walls would be constructed vertically through the levee prism, extending into or through deeper foundational soils that have low-permeability (a layer through which seepage does not flow readily). Thus, cutoff walls would substantially reduce the potential for under and through seepage flow during high-river events. Two methods for installing cutoff walls would be used along portions of the RD 17 levees: the conventional open-trench method and the deep soil mixing method.

The conventional open-trench method would be used to install shallow cutoff walls to a maximum depth of approximately 80 feet. This method involves excavating material in an open trench (the trench is filled with a bentonite slurry to maintain the side slopes of the excavation) and then replacing it with the select materials, typically a bentonite or cement-bentonite slurry (**Exhibit 8**). In this case, the top one-third to one-half of the levee height is “degraded,” meaning that it is excavated so that any weakness in the narrow upper portion of the levee does not result in failure of the levee during construction.

For the deep slurry mixing method, specialized equipment (such as augers) is used to excavate deep into the subsurface, allowing the cutoff walls to reach depths up to 120 feet (**Exhibit 9**). The deep slurry mixing method involves mixing the soil in place with cement and / or bentonite, thereby reducing the risk of failure during construction. This method does not require levee crown degradation.

For the Phase 3 Repair Project, the cutoff walls would be extended approximately 300 feet beyond the element boundary to provide the required overlap when drained seepage berms have been or are being installed along the landside of adjacent levee elements. Levee slopes (where cutoff walls would be installed) also would be modified as needed to achieve the required 20-feet width and landside 3:1 slope.

SETBACK LEVEE WITH SEEPAGE BERM AND UNDERLYING CUTOFF WALL

General Description of Setback Levees

A setback levee is a levee constructed some distance behind an existing levee. The setback is tied into the existing levee at the upstream and downstream ends of the setback area. After certification of the setback levee, all or a portion of the existing levee between these two points typically is removed to allow high-water events to inundate the newly expanded floodway. Soil from the old levee may be used as a source of fill for other levee improvement projects, depending on the quality and quantity of material generated from demolition of the old levee. In some cases, it may be necessary to continue maintaining the existing levee after a setback levee is constructed (e.g., to protect existing development in the setback area) and to use the newly constructed levee as a backup levee.

General Description of Proposed Setback Levee and Associated Floodplain Restoration

Project Element IVc involves construction of a 1,100-foot-long setback levee with an underlying cutoff wall and a seepage berm, on a major oxbow of the San Joaquin River (see Table 2). A *Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project* (Conceptual MMP) (RD 17 2016) has been prepared to describe the expansion and restoration of riparian habitat in Element IVc; this document is included as an attachment to this BA (Appendix E).

In the Phase 3 Repair Project area, soil materials beneath a setback levee are anticipated to have properties similar to those of materials below the existing levees. Therefore, a setback levee would have no seepage-related benefit in the RD 17 area relative to other seepage control methods; like the existing levees, a setback levee would require either a cutoff wall or drained seepage berm to sufficiently reduce the potential adverse effects associated with under seepage flows (**Exhibits 10** and **11**). Nevertheless, implementation of a setback levee could provide some additional capacity in the river for floodwaters and also would have the potential to provide habitat in the area between the new and old levee locations. In the Phase 3 Repair Project area, any newly expanded floodway created by a proposed setback levee would be designed to drain surface water after a high-water event, to prevent fish stranding.

Setback Levee Considerations

As described in greater detail under Section 2.1.4 in the DEIS/DEIR (USACE and RD 17 2011), and consistent with Section 2.5.1 of the forthcoming Final Environmental Impact Statement (FEIS) (USACE *in prep.)* for the proposed project, setback levees were considered but eliminated from further consideration in several project reaches for the following reasons:

- Construction of a setback levee along certain stretches of the river would be hydraulically constrained and would greatly increase the project scope to the point of being cost prohibitive (elements VIa.4 and VIb).
- Because of the proximity to the bifurcation at Old River, the change in hydraulic conditions that would result from constructing a setback levee at these locations would increase flows down the San Joaquin River during flood events, which could lead to increased flooding downstream (elements Va and VIa.1).
- Construction of a setback levee relative to other levee improvement alternatives and/or land acquisition to accommodate construction of a setback levee would be cost prohibitive (elements Ia, Ie, IIIb, IVa, VIcde, and VIIb).
- Existing landside development would constrain the option of constructing a setback levee (elements IIab, VIIe, and VIIg).

The complete hydraulic analyses that evaluated the setback levee alternatives are included as **Appendix F**.

Tie-in to Existing Levee

Where the new setback levee would intersect the existing levee, the top one-third to one-half of the crown of the existing levee would be degraded beginning with a 1:1 cut at the existing waterside crown to facilitate tying the cutoff wall and setback levee into the existing levee.

Riprap

Approximately 0.64 acres (740 linear feet) of riprap would be installed only on the waterside of the existing levee and above the HTL in element IVc where it would intersect the setback levee. No trees/shrubs would be removed to place the riprap and any riprap around trees/shrubs would be hand-placed. The riprap would not be installed to act as launchable rock.

Remnant Levee Breach

After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 8 acres of floodplain to the river.

Floodplain Offset Area

The reconnected floodplain area would be graded to allow complete drainage of the floodplain to the river. The floodplain would be graded to drain to a central swale, approximately 2-feet deep. As flood flows recede, the swale would drain completely through the breach in the remnant levee. This would minimize the possibility of fish stranding. The periodic reactivation of floodplain rearing habitat for juvenile salmonids, in particular, and other native fishes as well would be a benefit to fish resources. The seasonal nature of inundation, along with complete drainage, would preclude establishment in the floodplain of predatory, non-native fishes.

The Conceptual MMP evaluates three breach invert elevations (8 feet [NAVD88], 10 feet [NAVD88] and 14 feet [NAVD88]) for the proposed levee breach on the downstream end of the oxbow. Hydraulic modeling, based on San Joaquin River flows as reported at the Vernalis USGS stream gage (Vernalis gage), about 17.5 miles upstream of the project area, was used to estimate the flow in the San Joaquin River at which water would enter the setback area through the remnant levee breach for the three breach invert elevations. The results are shown in Table 3.

To evaluate how often and how long the levee setback area would be expected to inundate, a review was made of the historical Vernalis gage daily flow records since the completion of New Melones Dam in 1979 (this represents a period where the San Joaquin River basin operating regime has been relatively unchanged). The evaluation used the mean daily flows for the period October 1, 1978 through September 30, 2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. Table 4 summarizes the estimated number and percent of days in the evaluation study period in which the levee setback area would flood based on the three invert elevations. Based on the historical data, the periods during which water would flow into the project breach at the three invert elevations are displayed in the figures below.

The appropriate breach elevation is under consideration and will be defined in the Final MMP. It is anticipated that the breach elevation would be set at approximately 9 or 10 feet (NAVD88). Approximately 1-2 acres of the floodplain would be set to an elevation of 14 feet (NAVD 88) or below and would inundate approximately every 6 years.

RAISED LANDSIDE GRADE

Directly adjacent to the landside toe of the levee in element Ib, an approximately 5-foot-deep depression was used as a borrow site to facilitate construction of the Howard Road Bridge. RD 17 would place fill within this depression to raise the landside grade.

Table 3 Estimated Flows for Inundation of the Element IVc Mitigation Site			
Breach Invert Elevation (feet, NAVD88)	Flow in San Joaquin River near Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Estimated Return Interval	Flow in San Joaquin River at Breach Location (cfs)
8	9,500	2 year	4,200
10	13,200	3 to 4 year	5,700
14	24,000	6 year	8,800
Note: cfs = cubic feet per second Source: MBK Engineers 2016			

Table 4 Estimated Total Duration of Mitigation Site Flooding for Evaluation Period of Record			
Breach Invert Elevation (feet, NAVD88)	San Joaquin River Flow at Vernalis above which Mitigation Site Breach Flow Occurs (cfs)	Number of Days Flow Equaled or Exceeded Since 10/1/1978	Percent of Days Flow Equaled or Exceeded Since 10/1/1978
8	9,500	1,619	12%
10	13,200	1,126	8.3%
14	24,000	423	3.1%
Note: cfs = cubic feet per second Source: MBK Engineers 2016			

ADDITIONAL PROJECT COMPONENTS

The following additional activities would occur as part of the Phase 3 Repair Project:

- **Levee geometry corrections:** Phase 3 Repair Project elements currently do not meet requirements for levee geometry (i.e., slopes, crown width). To correct levee geometry, levee fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot-wide levee crown. All elements would undergo some level of levee geometry corrections.

- **Operations and Maintenance (O&M) access and utility corridors:** A 20-foot-wide permanent O&M access corridor[4] would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.

- **Temporary construction easements:** Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the site(s) would be returned to pre-project conditions following completion of construction.

- **Stormwater /irrigation controls:** Drainage/irrigation swales would be constructed around the outside boundaries of levee repairs, where needed, and other stormwater best management practices (BMPs) would be implemented to manage stormwater runoff and/or irrigation during and after construction. These swales would be located so that they would not drain to/from wetlands or other waters of the U.S.

4 The CVFPB would require that a 20-foot-wide access corridor be established. However, on a case-by-case basis, effects on woody vegetation within this corridor may be avoided in place. However, for the purposes of the analysis in this FEIS, it was assumed that any vegetation within the 20-foot-wide corridor would be removed.

- **Right-of-way acquisition:** Lands within the Phase 3 Repair Project footprint would be acquired as needed, to accommodate levee repairs (e.g., seepage berms, setback levees) and establish the minimum 20-foot-wide O&M access corridor at the landside toes of all the improved levees, to prevent encroachment. Privately owned lands would be acquired in fee preferably, but may be taken as easements if needed. Where the project footprint overlies land owned and managed by other agencies (i.e., the City of Lathrop, San Joaquin County, Union Pacific Railroad [UPRR]), either the land would have to be acquired in fee or easements would have to be obtained and secured. Real property acquisition and any relocation services, if needed (although no relocations are anticipated), would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 USC 4601 et seq.) and implementing regulation, Title 49 of CFR Part 24, and California Government Code Section 7267 et seq.

- **Haul roads:** An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and cement) would be required to construct these levee improvements. These materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Phase 3 Repair Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would be public roadways, on and within 300 feet of the levees, existing unpaved roads used for access to work areas, and levee patrol roads atop the levee crown.

- **Landside vegetation removal:** Landside vegetation within the footprint of the proposed levee work, including maintenance roadway corridors and temporary access easements, would be cleared to prepare for levee repair work. The proposed action would involve performing limited work on the waterside of the levee above the HTL (e.g., installing riprap and degrading a portion of the levee in element IVc); however, no waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Encroachment management:** Several features, including power poles, vegetation, and a variety of agricultural-related facilities (e.g., irrigation infrastructure, fences), are within the Phase 3 Repair Project footprint. Utility infrastructure would be relocated as needed to accommodate the levee repairs, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Phase 3 Repair Project area would be removed or relocated as required to meet the criteria of USACE, the CVFPB, and FEMA. No waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Long-Term Vegetation Management:** Vegetation on the levees and within the access easements would be managed in accordance with current O&M practices to maintain access and visibility. These practices include: mechanical trimming of existing trees and removal of large dead and downed trees annually, as described under "Compliance with USACE Vegetation Management Standards"; regular summer and winter application of herbicides for weed control; and summer application of herbicides to control woody plants and berries.

Proposed Schedule and Sequence of Project Construction

Construction of the Phase 3 Repair Project is scheduled to begin in 2018, and is expected to be completed by December 2019, assuming receipt of all required environmental clearances, permits, and approvals for implementation. Some related activities, such as relocating power poles, may be conducted before levee work is begun, and site restoration and demobilization could extend through spring 2020. The general levee construction window is seasonal (July 1–November 1), avoiding the period when high-water levels have the potential to occur within the San Joaquin River system. However, depending on hydrologic conditions and subject to compliance with species work windows, a work window variance that allows an extension outside the July 1–November 1 work period may be granted by the CVFPB. The CVFPB may stipulate that RD 17 has to comply with additional conditions and commitments as a component of any work window variance.

The proposed construction sequence, which would include concurrent work in several different elements to meet the project schedule, is as follows:

- **Relocation of power poles:** Power poles currently situated on the landside of the levee toe of some elements would need to be relocated to accommodate proposed drained seepage berms. To the extent feasible, power poles would be relocated beyond the toe of the new berm, outside the maintenance access easement. If placing poles on top of the seepage berms is required, either raised foundations or steel-reinforced concrete piers would be constructed to prevent the poles from affecting the seepage berms. RD 17 would oversee relocation of the power poles, in coordination with the appropriate utility and construction companies.

- **Site preparation at existing levee sites and in levee setback area:** Site preparation (i.e., clearing, grubbing, and stripping) of the levee elements would begin by clearing structures (see discussion in next bullet) and woody vegetation from the footprint of the proposed levee work and the permanent O&M access and utility corridors. Vegetation would be retained in areas adjacent to but outside the project footprint. This operation would require removal of some trees and relocation or removal of some elderberry shrubs. Large trees would be felled approximately 3 feet above ground level, with stumps temporarily left in place. Where feasible, small trees and elderberry shrubs would be relocated. Elderberry shrubs would be relocated, in accordance with the avoidance and minimization measures outlined (see "Avoidance and Minimization Measures – Valley Elderberry Longhorn Beetle" subsection of this BA). A minimal amount of belowground disturbance would occur. The clearing operation would be followed by grubbing operations to remove stumps, root balls, and any below-ground infrastructure. The area then would be disked to chop surface vegetation and mix it with near-surface organic soils. The disking operation would be followed by stripping the top 12 inches of earthen material from the landside slope of the existing levee and the footprint of the proposed seepage berms. Excess earthen materials (i.e., organic soils, and excavated material that does not meet levee embankment criteria) would be temporarily stockpiled and then would be re-spread on the surface of the new levee slopes and seepage berms, provided this material is not contaminated with vegetation. Any stripped material contaminated with vegetation and other debris generated during the clearing and grubbing operations would be hauled off-site to a suitable landfill.

- **Removal or modification of landside structures and other facilities:** In a few levee elements, agricultural facilities (e.g., fences, drainage infrastructure) or parking lots are located within the footprint of the proposed levee work. These facilities would be removed from or relocated outside the project footprint before levee construction begins in those areas. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Demolished concrete could be sent to a concrete recycling facility. If any wells or septic systems would be affected, they would be abandoned in accordance with the applicable State and County requirements.

- **Construction of the setback levee with drained seepage berm and underlying cutoff wall:** Construction of the setback levee embankment in element IVc would begin as soon as sufficient lengths of levee foundation are prepared and weather conditions are suitable. Foundation preparation would include constructing a levee keyway that would be excavated 3–5 feet deep across the entire footprint of the proposed setback levee. A smaller but deeper excavated inspection trench, centered beneath the new waterside hinge point of the setback levee, then would be constructed beneath a small portion of the keyway to meet DWR standards. After the foundation layers are backfilled with engineered soil, a geotechnical geogrid fabric would be installed at ground level across the entire setback levee footprint. A second layer of geogrid fabric would be placed at mid-height of the new levee fill section to further reduce the potential for post-construction settlement of the new levee. The embankment would be constructed of engineered fill, with the fill placed in 3-foot-maximum lifts by motor graders. Each lift would be moisture-conditioned using water trucks and would be compacted to the specified density using a suitable compactor, such as a sheep's foot, tamping foot, or rubber-tired roller. Next, quarry stone riprap would be applied in three segments, to armor the newly completed setback levee's waterside slope and protect against erosion. Riprap would be placed on the waterside levee above the HTL in areas that are characterized by ruderal land cover (**Exhibit 12**). All waterside woodland would be avoided; all waterside trees would be avoided as well as any tree canopy that

overlaps riprap. Riprap placement would be done either by barge or by long-arm excavator from the top of the levee crown. Riprap dimensions for the three segments are: 340 feet long by 50 feet wide (0.39 acre), 140 feet long by 30 feet wide (0.096 acre), and 230 feet long by 50 feet wide (0.26 acre). A drained seepage berm then would be constructed on the landside of the setback levee. Fill material for setback levee and drained seepage berm construction would be obtained from commercial sources and would be delivered to levee construction sites using haul trucks.

- **Setback levee site restoration and demobilization:** After completion of construction, the previously stripped topsoil material would be placed on top of the completed setback levee and associated seepage berms in element IVc, and levee slopes and the tops of the seepage berms would be hydroseeded. An aggregate-base patrol road would be constructed at the landside edge of the seepage berm and setback levees and on the new setback levee crown. The existing levee would be fully restored at the tie-in points to the new setback levee. The existing levee crown patrol road would be redressed with aggregate base, to restore it to preconstruction levels. Any disturbed riprap also would be supplemented to provide a uniform layer across the connection point with the new setback levee. Immediately after final construction, the setback levee's fill slopes would be covered with erosion control material until application of the hydroseed. Any construction debris would be hauled to an appropriate off-site waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization would be likely to occur in various locations as construction proceeds along various elements.

- **Removal of existing levee at setback levee elements, site restoration, and demobilization:** After certification of the new setback levee and seepage berm in element IVc, a 400-linear-foot-long section of the existing outboard levee (which is approximately 2,400 linear feet long in element IVc) on the downstream side of the existing oxbow would be partially degraded. The area where the levee would be degraded is characterized by ruderal land cover (**Exhibit 13b**); some landside vegetation would be removed (as accounted in the "Direct and Indirect Effects on Species in the Action Area" section of this BA, but all waterside trees and overlapping tree canopy would be avoided. At least 9.9 acres (and up to 11.5 acres) of riparian vegetation would be established in the area between the new setback levee and the river (**Exhibit 12**) (see the "Compensation Measures" subsection of the "Avoidance and Minimization Measures" section below for additional information). This acreage would be made up of approximately 0.5 acre of floodplain swale and approximately 4.5 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee; approximately 2.5 acres of enhanced riparian scrub habitat between the river and the waterside toe of the existing levee; and approximately 4 acres of restored Great Valley oak woodland/upland refugia habitat along the existing levee. These acreages would include approximately 1.6 acres of contingency, with the goal of restoring a minimum of 9.9 acres of riparian habitat. This work would be completed after flood season (from July 1 through November 1) and above the HTL, primarily using scrapers, excavators, and bulldozers to remove the levee section and all present levee encroachments.

- **Construction of drained seepage berms, drained seepage berms with chimney drains, and chimney drains within existing drained seepage berms:** Fill material for levee improvements would be obtained from commercial sources and delivered to the levee construction sites by haul trucks. The material then would be spread by motor graders and compacted by sheep's foot rollers to build new seepage berms and seepage berms with chimney drains. A water truck would be used to properly moisture-condition the soils for compaction. Installing the chimney drains in existing drained seepage berms also would require use of an excavator or scraper to remove the existing drained seepage berm fill material so that the chimney drain fill material can be tied into the drainage rock layer of the existing drained seepage berm.

- **Construction of cutoff walls:** Cutoff wall construction is anticipated to occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance, when necessary. Lights and possibly power generators would be used during nighttime construction hours. Additional equipment would include slurry batch plants to prepare bentonite or bentonite cement mix, pumps, and support vehicles. Four to five batch plants or slurry ponds would be required for the project; these would be located near the site of cutoff wall construction. Each batch plant or slurry pond with associated pumps and support equipment would occupy an area of approximately 100 square feet that would be restored to pre-project conditions following completion of cutoff wall construction. Cutoff walls may be installed concurrently in two or more different directions within an element. RD 17 proposes to use the deep slurry mix method for installing deep cutoff walls, which would avoid the need to degrade the top of the levee, and conventional slurry trench walls (open-cut method) for shallow cutoff walls. RD 17 also would consider driving sheet piles, using a drop impact hammer or other pile-driving technology in lieu of cutoff wall installation at element VIIe. The number of cutoff wall rig setups would depend on the project schedule and contractor preference. Each deep slurry mix cutoff wall rig would move continuously along the proposed alignment, to attain an uninterrupted cutoff wall and reduce prolonged disturbance to residences near some cutoff wall segments. Each cutoff wall rig could move 50 to 100 feet horizontally during a 12-hour work shift, while each conventional slurry trench rig could move 75 to 200 feet horizontally during a 12-hour work shift. Disturbances to nearby residences are expected to be minor because of the limited number of residences near the cutoff wall installation areas. However, where lights, noise, and/or vibration would exceed allowable nighttime standards for the applicable local jurisdiction, work hours would be restricted to daytime work hours.

- **Traffic control during construction:** Traffic control and detours could be required in the immediate vicinity of some levee improvements. Traffic control measures would include flaggers for one-way traffic control, advance construction signs and other public notices to alert drivers to activity in the area, and “positive guidance” detour signage on alternate access roads to reduce inconvenience to the driving public. Detours for through traffic are not likely to be required.

- **Site restoration and demobilization:** On completion of construction, previously stripped topsoil material not contaminated with vegetation would be placed on top of the completed seepage berms and any disturbed levee slopes. Any previously nonagricultural, vegetated areas disturbed during construction would be hydroseeded with a standard erosion control mix. An aggregate-base patrol road would be constructed at the landside edge of any seepage berms. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization likely would occur in various locations as construction proceeds along various elements.

DESCRIPTION OF THE 2017 EMERGENCY RESPONSE CONSTRUCTION PROJECT ACTIONS

The 2017 Emergency Response Construction Project that was implemented in February 2017 included the construction of seepage berms and raised landside grades in several elements (see **Appendix G** for as-builts). Most of these activities were already planned under the Phase 3 Repair Project. All the seepage berms and raised landside grades that were installed for the emergency response, even those where cutoff walls will be done in the future as proposed under the Phase 3 Repair Project, would remain in place. **Table 5** summarizes, for each project element, the emergency construction actions that were implemented in 2017, as well as the remaining actions that would occur under the Phase 3 Repair Project.

Table 5
Summary of 2017 Emergency Response Construction Project Actions

Element	Emergency Response Construction Project Actions	Remaining Phase 3 Repair Project Actions
Ia	Constructed approximately 350’ of seepage berm, as proposed.	Construct PG&E High Voltage Tower footing raisings, approximately 240’ of additional seepage berm, and approximately 590’ of chimney drain.
Ib	Constructed approximately 130’ of seepage berm and grade raising, as proposed.	Construct approximately 130’ of chimney drain.
Ie	Constructed approximately 500’ of seepage berm, as proposed.	Construct approximately 500’ of chimney drain.

Table 5 Summary of 2017 Emergency Response Construction Project Actions		
Element	**Emergency Response Construction Project Actions**	**Remaining Phase 3 Repair Project Actions**
IIab	*None.*	Construct approximately 2,600’ of cutoff wall and levee widening.
IIIa	*None*	Construct approximately 4,750’ of chimney drain in existing seepage berm and widen levee slope.
IIIb	Constructed approximately 650’ of seepage berm, as proposed.	Construct approximately 650’ of chimney drain.
IVa	Constructed approximately 450’ of seepage berm, as proposed.	Construct approximately 450’ of chimney drain.
IVc	*None.*	Construct approximately 1,100’ long setback levee containing 300’ of seepage berm and 300’ of cutoff wall. A new waterside habitat area will also be developed on the remnant ground outside the new setback levee (see **Appendix E** of this document).
Va and VIa.1	Constructed approximately 5,800’ of seepage berm. ***This was not previously proposed but would remain in place.***	Construct approximately 9,500’ of continuous cutoff wall. The existing levee will be widened where necessary as part of cutoff wall construction.
VIa.4	*None.*	Install 70’ of cutoff wall to meet required exit gradients.
VIb	*None.*	Construct approximately 2,050’ of cutoff wall.
VIcde	Constructed approximately 300’ of seepage berm at element VIc (as proposed), constructed approximately 150’ of seepage berm and grade raising at element VId (as proposed), and constructed approximately 200’ of parking lot grade raising at element VIe (as proposed). Constructed approximately 200’ of subgrade seepage collection drain system and parking lot improvements.	Construct approximately 300’ of chimney drain and a new earthen railroad embankment to replace the existing wooden trestle bridge at element VIc, construct approximately 150’ of chimney drain at element VId, and construct approximately 200’ of chimney drain and levee widening.
VIIb	Constructed approximately 250’ of seepage berm, as proposed.	Construct approximately 250’ of chimney drain.
VIIe	*None.*	Construct approximately 2,500’ of cutoff wall.
VIIg	*None.*	Construct approximately 400’ of seepage berm and grade raising.
Source: Data provided by Kjeldsen, Sinnock & Neudeck, Inc. in 2017		

All of the emergency response construction project components were included within the Phase 3 Repair Project, except for the new seepage berm that was constructed in elements Va and VIa.1. This seepage berm was evaluated in the FEIS ((USACE *in prep.)* under Alternative 2 – Maximum Footprint, but not carried over into the Preferred Alternative, which is the Phase 3 Repair Project. However, this seepage berm overlaps with the footprint for the Phase 3 Repair Project (compare Exhibit 13b, in Appendix A, to Sheets 9 and 11 of Appendix G).

AVOIDANCE AND MINIMIZATION MEASURES

The following avoidance and minimization measures would be implemented as a component of the Phase 3 Repair Project. The measures, where applicable, were implemented during the 2017 Emergency Response Construction Project (see “Effects Related to the 2017 Emergency Response Construction Project Actions” subsection under the “Direct and Indirect Effects on Species in the Action Area” section of this document).

GENERAL

A qualified biologist, retained by RD 17, will be on-site to ensure compliance with the avoidance and minimization measures described below, particularly where construction activities occur adjacent to sensitive habitats to be avoided.

A worker awareness training program will be conducted for construction crews before the start of construction. The program will include a brief overview of special-status species and sensitive resources (including riparian habitats) in the Phase 3 Repair Project area, measures to avoid and minimize effects on those resources, and conditions of relevant regulatory permits.

Furthermore, traffic speeds on unpaved roads will be limited to 15 miles per hour, to reduce dust emissions and minimize potential effects on listed species, such as the riparian brush rabbit.

VALLEY ELDERBERRY LONGHORN BEETLE

For elderberry shrubs that are located in the Phase 3 Repair Project area, RD 17 will implement the following avoidance and minimization measures that are described in the Conservation Guidelines for the Valley Elderberry Longhorn Beetle (VELB Guidelines; USFWS 1999), to avoid and minimize effects on VELB:

- All elderberry shrubs that are located adjacent to construction areas but can be avoided will be protected by establishing a fenced avoidance area. The fencing will be placed at least 20 feet from the dripline of the shrubs. All elderberry shrubs to be protected during construction will be identified and marked by a qualified biologist. Orange construction barrier fencing will be placed at the edge of the respective buffer areas, and no construction activities will be permitted within the buffer zone other than those activities necessary to erect the fencing. In cases where the elderberry dripline is less than 20 feet from the work area, k-rails will be placed at the shrub's dripline to provide additional protection to the shrubs from construction equipment and activities. Temporary fences around the elderberry shrubs and, where appropriate, k-rails at shrub drip lines will be installed as the first order of work. Buffer area fences around elderberry shrubs will be inspected weekly by a qualified biologist during ground-disturbing activities, until adjacent project construction is complete or the fences are removed on approval by a qualified biologist and the resident engineer.
- No insecticides, herbicides, or other chemicals that may harm the beetle or its host plant will be used within 100 feet of elderberry shrubs.
- Elderberry shrubs that require removal will be transplanted to a USFWS-approved site during the dormant period for elderberry shrubs (i.e., November 1 to February 15) and in accordance with the VELB Guidelines (USFWS 1999).
- Each elderberry stem measuring 1 inch or greater in diameter at ground level that may be adversely affected (i.e., transplanted) will be replaced with elderberry seedlings and seedlings of associated species, in accordance with the VELB Guidelines (USFWS 1999).

Regarding provision for off-site compensatory mitigation for habitat losses, see the "Compensation Measures" subsection below.

RIPARIAN BRUSH RABBIT

The following measures will be implemented to avoid and minimize potential adverse effects on riparian brush rabbit in potential habitat within and adjacent to the Phase 3 Repair Project footprint (i.e., Great Valley cottonwood and Great Valley oak riparian forest communities):

- Potential riparian brush rabbit habitat will be identified and avoided wherever possible. The primary engineering and construction contractors will ensure, through coordination with a qualified biologist who is pre-approved by USFWS and retained by RD 17, that construction will be implemented in a manner that minimizes disturbance of such areas to the extent feasible.
- Temporary fencing will be used during construction to prevent disturbance of potential habitat adjacent to construction areas. Construction personnel, vehicles, and equipment will remain within the identified construction area. In addition, a silt fence or other suitable temporary barrier will be installed around the construction area where it borders suitable habitat for brush rabbits, to exclude brush rabbits from the construction site; this silt fence or temporary barrier either will be incorporated into the temporary fencing or will be installed as a separate fence. Temporary signage will be placed along the rabbit exclusion fence at 150-foot intervals, warning contractors to stay within the construction area. The temporary rabbit exclusion fence and associated signage will be inspected by a qualified biologist and the construction contractor each morning before the beginning of construction activities, and will be repaired and maintained as necessary. A biological monitor will inspect the fence at least once a week. The temporary rabbit exclusion fence and signage will be removed after construction activities are no longer occurring adjacent to the exclusion area.
- Where suitable habitat for riparian brush rabbit has to be removed, vegetation will be removed by hand 2 weeks before the start of construction so that no riparian brush rabbits are present in the construction area at the time of construction. A qualified biologist, retained by RD 17, will be on-site during vegetation removal. Areas of temporary habitat disturbance in the Phase 3 Repair Project area will be revegetated with native plant species and restored to pre-project conditions.

Regarding provision for on-site compensatory mitigation for habitat losses, see the “Compensation Measures” subsection below.

FEDERALLY LISTED FISH—DELTA SMELT, LONGFIN SMELT, ANADROMOUS SALMONIDS, AND GREEN STURGEON (WATER QUALITY)

The following measures will be implemented to avoid and minimize potential adverse effects on water quality:

- Any work within the existing floodway (i.e., placing riprap on the waterside levee above the HTL at element IVc) of the San Joaquin River will not take place during the designated flood season (i.e., November 1 to July 1) and will not begin until evaluation of upstream conditions (e.g., reservoir storage and snowpack) indicate that inundation of these areas will be unlikely to occur during construction.
- RD 17 will comply with all local, State, and federal regulations and environmental requirements regarding turbidity-reduction measures, including the following:
    - obtaining and complying with relevant agency permits (e.g., CDFW streambed alteration agreement, Central Valley Regional Water Quality Control Board [RWQCB] Clean Water Act Section 401 certification, and Section 404 permit);
    - developing and implementing a storm water pollution prevention plan (SWPPP) that identifies specific BMPs to avoid and minimize effects on water quality during construction activities; and
    - complying with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity.
- RD 17 will file a notice of intent with the Central Valley RWQCB to discharge stormwater associated with construction activity. Final design and construction specifications will require implementation of standard erosion, siltation, and good housekeeping BMPs. Construction contractors will be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for

construction activity (Order No. 2009-0009-DWQ or the current permit in place at the time of construction). The SWPPP will describe the construction activities to be conducted, BMPs that will be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that will be conducted.

At a minimum, the following specific BMPs will be implemented:

- All work will be conducted according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized.
- Silt fences and/or straw wattles will be installed near riparian areas or existing drainages to control erosion and trap sediment and reseed cleared areas with native vegetation.
- Maintenance will be conducted on a regular basis to ensure proper installation and function of BMPs, and during storm events, maintenance will be conducted daily.
- BMPs that have failed (within 48 hours of an event) will be repaired and replaced immediately with sufficient devices and materials (e.g., silt fence, coir rolls, and erosion blankets), provided throughout project construction to enable immediate corrective action for failed BMPs.
- Stockpiling of construction materials (e.g., portable equipment, vehicles, and supplies, including chemicals) will be restricted to designated construction staging areas, exclusive of any riparian, wetland, or other areas supporting waters.
- Disturbed soils at construction areas will be stabilized before the onset of rainfall.
- Stockpiles will be stabilized and protected from exposure to rain and potential erosion.

The SWPPP also will specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of effects from use or accidental spills or releases of contaminants. Specific measures applicable to the project will include the following:

- Compliance will be required by RD 17 contractors with all applicable State Water Resources Control Board (SWRCB) and Central Valley RWQCB standards and other applicable water quality standards.
- Strict on-site handling rules will be developed and implemented, to keep potentially contaminating construction and maintenance materials out of drainages and other waterways.
- When refueling and servicing equipment, absorbent material or drip pans will be used underneath such equipment to contain spilled fuel, oil, and other fluids; and any fluid drained from machinery will be collected in leak-proof containers and deliver to an appropriate disposal or recycling facility.
- Controlled construction staging and fueling areas will be maintained at least 100 feet away from channels or wetlands, to minimize accidental spills and runoff of contaminants in stormwater.
- Substances that can be hazardous to aquatic life will be prevented from contaminating the soil or entering watercourses.
- Spill cleanup equipment will be maintained in proper working condition. All spills will be cleaned up immediately according to the spill prevention and response plan, which will be prepared by RD 17 or its contractor or representative and will be approved by the RWQCB before the start of project ground-breaking.

- NMFS, USFWS, CDFW, and the Central Valley RWQCB will be notified immediately (within 24 hours) of any reportable spills and cleanup occurrences. All such spills, and the success of the efforts to clean them, will be recorded in post-construction compliance reports.
- A slurry spill contingency plan will be developed, which will be prepared by RD 17 or its contractor or representative before the start of project groundbreaking, to respond to a potential for bentonite slurry spill and prevent slurry from entering watercourses.
- Construction materials handled by RD 17 or its contractors will be stored and transported in a manner that minimizes potential water quality effects. Storage areas will be located away from drainages and waterways, outside the floodplain, and away from sensitive resources, and containment facilities will be used.

BMPs will be applied to meet the “maximum extent practicable” and “best conventional technology/best available technology” requirements and address compliance with water quality standards. RD 17 will implement a monitoring program during and after construction so that the Phase 3 Repair Project complies with all applicable standards and BMPs implementation is effective.

COMPENSATION MEASURES

VALLEY ELDERBERRY LONGHORN BEETLE

As described above under “Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle,” compensation for effects on VELB will be provided in accordance with the VELB Guidelines (USFWS 1999). Elderberry shrubs that cannot be avoided will be transplanted to the levee setback area in element IVc (**Exhibit 12**). The restoration design, as outlined in the Conceptual Mitigation and Monitoring Plan for the Riparian Brush Rabbit (Conceptual MMP; **Appendix E**), will include elderberry seedlings and associated species plantings to compensate for the effects on VELB habitat in the Phase 3 Repair Project site. Transplanting unavoidable elderberry shrubs and planting elderberry seedlings and associated species (in an amount determined through compliance with the VELB Guidelines) will fully compensate for the loss of VELB habitat resulting from construction activities associated with the Phase 3 Repair Project.

RIPARIAN BRUSH RABBIT

Compensation for effects on riparian brush rabbit habitat will consist of restoring natural habitats in the Phase 3 Repair Project area.

As described in more detail in the Conceptual MMP (**Appendix E)**, on-site compensation for adverse effects on riparian brush rabbit habitat will include restoration of at least 9.9 acres of riparian habitat in the proposed levee setback area in element IVc. This acreage will be made up of approximately 0.5 acre of floodplain swale and approximately 4.5 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee; approximately 2.5 acres of enhanced riparian scrub habitat between the river and the waterside toe of the existing levee; and approximately 4 acres of restored Great Valley oak woodland/upland refugia habitat along the existing levee. The total of amount of potential compensatory mitigation acreage is approximately 11.5 acres, which will allow approximately 1.6 acres of contingency to achieve the compensation for riparian brush rabbit habitat.

After the new setback levee is constructed and certified in element IVc, a small 400-foot section of the existing levee will be partially degraded. Native riparian scrub vegetation will be established within the entire setback area floodplain. Species in the plant palette will be those preferred by the riparian brush rabbit for providing cover, including: California blackberry (*Rubus ursinus*), California wild rose (*Rosa californica*), sandbar willow (*Salix exigua*), coyote brush (*Baccharis pilularis*), and golden currant (*Ribes aureum*), among others. Understory vegetation will include herbaceous species that have been identified as preferred forage by the riparian brush rabbit, such as mugwort (*Artemisia douglasiana*) and gumplant (*Grindelia camporum*). To provide refugia during flood events, the old levee footprint also will be vegetated with riparian scrub and riparian woodland tree species. The upland refugia will include elderberry seedlings and associated species plantings to compensate the effects on VELB habitat in the Phase 3 Repair Project area. In addition to plantings within the setback area, waterside riparian vegetation will be enhanced with plantings in open areas.

Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4.5 acres of ruderal grassland that can be restored as riparian scrub habitat (**Exhibit 12**). Approximately 2.5 additional acres of riparian scrub habitat will be restored and/or enhanced between the waterside toe of the existing levee and the river. The restored riparian scrub habitat will consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee will remain in place and approximately 4 acres of Great Valley oak woodland will be established on it, thus providing upland refugia for the riparian brush rabbit during high-water events.

Approximately a 3:1 restoration to impact mitigation ratio (for effects on potential riparian brush rabbit habitat) will be accomplished in the restoration area, with approximately 9.9 acres (and up to 11.5 acres) of riparian brush rabbit habitat restored. The expansion and restoration of riparian habitat in element IVc will augment the waterside riparian corridor along the San Joaquin River and will provide additional riparian habitat for the riparian brush rabbit between two known occurrences of this species (i.e., between elements IIIa/IIIb and elements VIa.1/VIa.4 [CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). The restoration area will be contiguous with existing waterside riparian habitat along element IVc; this waterside riparian habitat along element IVc extends northward through elements IVa, IIIa, and IIIb, and southward through elements Va and VIa.1. Documented occurrences exist of riparian brush rabbit in the waterside riparian habitat in elements IIIa and IIIb, and north of element IIIa and south of element VIa.1; therefore, reestablishing and protecting riparian habitat in element IVc will provide expanded and connected habitat for this species. This habitat creation and enhancement will fully compensate for the loss of habitat for riparian brush rabbit resulting from construction activities associated with the Phase 3 Repair Project.

Mitigation and Monitoring Plan

A Conceptual MMP has been prepared to describe the expansion and restoration of riparian habitat in element IVc (**Appendix E**). Specifically, this plan:

- describes specifications for the restoration of habitat components, including details about the restoration of riparian habitats, with a list of the plant species and drawings/designs to show the location of the plant species and planting density;
- establishes specific success criteria for the habitat components, including:
    - performance standards to determine whether the habitat improvement was trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions);
    - monitoring and maintenance protocols; and
    - measurable goals to ensure vegetation survival to provide and replace riparian habitats;
- specifies remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring); and
- describes short and long-term management and maintenance of the habitat lands.

The Conceptual MMP is intended to be developed into a Final MMP, in coordination with USFWS, NMFS, and USACE, and would be reviewed and approved by USFWS and NMFS before ground-breaking in the portions of the Phase 3 Repair Project area that could affect the species addressed in this BA. RD 17 would provide conservation of the restored riparian habitat in the levee setback area in element IVc. The compensation habitat ultimately would be transferred to a suitable land management organization, for long-term management and monitoring. This habitat creation and enhancement would fully compensate for the loss of habitat for VELB and riparian brush rabbit resulting from construction activities associated with the Phase 3 Repair Project.

ACTION AREA

The action area is defined in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project and the 2017 Emergency Response Construction Project.

Areas downstream from the Phase 3 Repair Project area also may be indirectly affected by the flood risk management component of the project, through improved water quality and flood risk management conditions. The extent of this potential effect is difficult to quantify, however, for element IVc; construction of a setback levee and breaching a small downstream portion of the existing levee would be expected to create a backwater effect and would not result in a substantial widening of the flood plain. An analysis also was conducted to evaluate the hydraulic effects of the setback levee at element IVc. This hydraulic analysis showed that the proposed action would essentially have no effect on the maximum water surface elevation, with a computed maximum increase in the water surface elevation of 0.0007 feet, and maximum flow rate changes would be negligible during extreme events (100-year flood recurrence interval). Because far afield project-related hydrologic effects are not likely to occur, the action area is concluded to be in the immediate vicinity of the actual project boundaries.

ENVIRONMENTAL BASELINE

HYDROLOGY

SACRAMENTO–SAN JOAQUIN DELTA

The Delta extends inland from the confluence of the Sacramento and San Joaquin rivers west of Antioch to Sacramento on the Sacramento River and to near Mossdale on the San Joaquin River. The Phase 3 Repair Project area is in the southeastern portion of the Delta, within the legal boundary of the Delta as defined by Section 12220 of the California Water Code.

The legal Delta encompasses an area of approximately 851,000 acres (of which approximately 135,000 acres consist of waterway, marshland, or other water surfaces). The Delta is divided into a Primary Zone and a Secondary Zone, as defined by the Delta Protection Act of 1992. Land uses in the Primary Zone are regulated to protect the area for agriculture, wildlife habitat, and recreational uses. The Secondary Zone is the area outside the Primary Zone and within the legal Delta. Where urban development activities occur in the Secondary Zone, efforts should be taken to ensure that these activities do not adversely affect Delta waters, Primary Zone habitat, or recreational uses. The San Joaquin River delineates the boundary between the Primary Zone to the west and the Secondary Zone to the east. The Phase 3 Repair Project is located in the Secondary Zone.

The Sacramento River contributes roughly 75 to 80 percent of the Delta inflow in most years, and the San Joaquin River contributes about 10 to 15 percent; the Mokelumne, Cosumnes, and Calaveras rivers, which flow into the eastern side of the Delta, contribute the remainder. The rivers flow through the Delta and into Suisun Bay, San Pablo Bay, San Francisco Bay, and the Pacific Ocean. Historical annual Delta inflow averaged approximately 23 million acre-feet (MAF) between 1945 and 1995, with a minimum inflow of approximately 6 MAF in 1977 and a maximum of approximately 70 MAF in 1983. Water flowing into the Delta is used for urban and agricultural use, recreation, navigation, and wildlife and fisheries. The Delta provides drinking water for about 23 million Californians.

Freshwater inflows to the Delta vary greatly, depending on precipitation, snowmelt, and Central Valley Project (CVP) and State Water Project (SWP) water operations. During the summer months, most inflow to the Delta comes from regulated releases from SWP and CVP reservoirs. Both projects also withdraw large volumes of water from the Delta for agricultural and urban use. Precipitation in the project region occurs primarily from November through March, with the average annual precipitation ranging from about 8 inches near Tracy to approximately 17 inches near Lodi. Near Lathrop, the annual precipitation is approximately 12 inches.

Water movement in the Delta responds to four primary forcing mechanisms:

- freshwater inflows to the ocean;
- Delta exports and upstream diversions;
- operation of water control facilities such as dams, export pumps, and flow barriers; and
- the regular tidal movement of seawater into and out of the Delta.

In addition, winds and salinity behavior in the Delta can generate secondary currents that, despite being of low velocity, can be of considerable significance with respect to transporting contaminants and mixing different sources of water. Changes in flow patterns in the Delta, whether caused by export pumping, winds, atmospheric pressure, flow barriers, tidal variations, inflows, or local diversions, can influence water quality at drinking water intakes.

The Delta is a hydrologically complex region of interlacing channels, marshland, and islands. The Delta has been reclaimed into more than 60 islands and tracts, interlaced with about 700 miles of waterways. Some channels are edged with aquatic and riparian vegetation, but most are bordered by steep banks of earth or riprapped levees. Vegetation generally is removed from channel margins to increase flood flow capacity and facilitate levee maintenance. About 520,000 acres are devoted to farming. An approximately 1,100-mile network of levees protects the reclaimed land, most of which lies near or below sea level, from flooding. Some of the island interiors are as much as 25 feet below sea level.

Nearly 16.5 miles of the 19 miles of levees protecting RD 17 are considered federal project levees; the 2.6-mile dryland levee is not a federal levee. Federal project levees either were constructed by the federal government (typically through USACE) or were built by others and later brought under federal jurisdiction.

San Joaquin River

The San Joaquin River originates in the Sierra Nevada and enters the San Joaquin Valley at Friant Dam. Most of the flow in the lower San Joaquin River is derived from inflow from the Merced, Tuolumne, and Stanislaus rivers (Northeastern San Joaquin County Groundwater Banking Authority 2004). The 330-mile-long San Joaquin River, which drains a watershed area of 13,540 square miles from the Sierra Nevada to the Delta, contributes approximately 15 percent of the inflow to the Delta (Delta Protection Commission 2000). Flowing through portions of Fresno, Madera, Merced, Stanislaus, San Joaquin, Sacramento, and Contra Costa counties, the river has flows ranging from 1,500 cfs in dry years to more than 40,000 cfs in wet years (Friant Water Users Authority and Natural Resources Defense Council 2002).

Hydrologic conditions in the San Joaquin River basin are dominated by snowmelt from the Sierra Nevada. Before major water storage projects were completed on the San Joaquin River and its major tributaries, lower San Joaquin River flows generally peaked in late spring/early summer and dropped to low levels in the fall. Since completion of Friant Dam (1944), McClure Reservoir (1967 on the Merced River), Don Pedro Reservoir (1971 on the Tuolumne River), and New Melones Reservoir (1979 on the Stanislaus River), the lower San Joaquin River's seasonal flow pattern has changed substantially. Before 1944, based on 1923–1944 records, flow in the lower San Joaquin River tended to peak in May and June, with an average monthly flow of almost 11,000 cfs, and declined rapidly to an average monthly flow of approximately 1,200–1,300 cfs in August and September. Since 1979, the average monthly flow has peaked in March at just over 10,000 cfs, with a more gradual decline to approximately 2,400 cfs in August. In addition, the San Joaquin River is tidally influenced by the Delta and the San Francisco Bay. Tidal fluctuation in the San Joaquin River has been modeled to approximately the Vernalis tide gauge and the Airport Way crossing of the San Joaquin River, which is approximately 13 river miles upstream from the project site.

The SJRRP was established in late 2006, to implement the Stipulation of Settlement in *NRDC et al. v. Kirk Rodgers et al*. (Settlement). Authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act, included in PL 111-11. The goal of the SJRRP is to re-operate and increase the release of water from Friant Dam in accordance with the Settlement, and in a manner consistent with federal, State, and local laws, and future agreements with downstream agencies, entities, and landowners (Reclamation and DWR 2011). The Settlement establishes two primary goals:

- *Restoration Goal*—To restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish. To achieve the Restoration Goal, the Settlement calls for releases of water from Friant Dam to the confluence of the Merced River (referred to as Interim and Restoration Flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon.

- *Water Management Goal*—To reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim and Restoration Flows provided for in the Settlement. To achieve the Water Management Goal, the Settlement calls for recirculation, recapture, reuse, exchange, or transfer of the Interim and Restoration Flows to reduce or avoid impacts on water deliveries to all of the Friant Division long-term contractors caused by the Interim and Restoration Flows.

The SJRRP is to release Interim and Restoration Flows to the San Joaquin River from Friant Dam in accordance with the flow schedule presented in Exhibit B of the Settlement. The Settlement establishes the Recovered Water Account and recovered-water program, which make water available to all Friant Division long-term contractors who provide water to meet Interim or Restoration Flows so that the impacts of Interim and Restoration Flows on such contractors can be reduced or avoided.

LOCAL DRAINAGE

Stormwater runoff in the RD 17 area commonly is collected in agricultural ditches, channels, municipal stormwater sewers, or human-made ponds before being pumped to the San Joaquin River. Runoff from the area east of the San Joaquin River, along levee elements Ie and VIIb, is directed west through agricultural swales and ditches, and then is pumped into the river by means of private agricultural pumps. Runoff from developed lands adjacent to elements IVa, IVc, and VIa.4 is directed to the City of Lathrop's storm drainage system, held in detention basins, and ultimately pumped into the San Joaquin River through a municipal stormwater outfall. Runoff in the area around element VIIe, which encompasses the Oakwood Lake development, first flows into the artificial lake in the center of the development, and then is pumped into the river if lake levels become too high.

WATER QUALITY

Water quality in the Delta and portions of the San Joaquin River are heavily influenced by CVP and SWP operations. Generally, Delta water quality is best during the winter and spring months and poorer during the irrigation season and early fall. Water quality in the San Joaquin River is influenced by factors such as rain and snowmelt runoff, reservoir operations, and irrigation return flows in the San Joaquin river basin. Agricultural return flows commonly discharge elevated salt loads into the San Joaquin River. The SWRCB has set flow and water quality objectives at Vernalis, located just upstream from the Phase 3 Repair Project area. To meet the Vernalis objective, the U.S. Bureau of Reclamation supplements flows on the San Joaquin River with releases from New Melones Reservoir on the Stanislaus River (Northeastern San Joaquin County Groundwater Banking Authority 2004).

The latest version of the Section 303(d) list for California issued by the SWRCB (approved October 26, 2006) identifies an impaired status for waterways in the eastern Delta, including the lower San Joaquin River. Potential sources of pollution for all of the listed constituents in the basin include agriculture, urban runoff/storm sewers, resource extraction, and unknown sources. The eastern Delta, including the lower San Joaquin River, is on the Section 303(d) list for impairment from boron, chlorpyrifos, diazinon, dichlorodiphenyltrichloroethane, electrical conductivity, unknown toxicity, Group A pesticides, exotic species, and mercury. Downstream from the Phase 3 Repair Project area, the Stockton Deep Water Ship Channel is being addressed by a total maximum daily load (TMDL) plan for dissolved oxygen and is no longer on the Section 303(d) list. TMDLs have been initiated for organophosphorus pesticides (i.e., diazinon and chlorpyrifos), salinity and boron, and selenium in the lower San Joaquin River watershed and for total dissolved solids and mercury in Delta channels. TMDLs for the other listed pollutants are scheduled to be developed at various times over the next 10 years, in accordance with the priorities contained in the Section 303(d) list.

Major monitoring programs for the San Joaquin River include DWR's Municipal Water Quality Investigations Program and Water Rights Decision 1485 Water Quality Monitoring Program. The City of Stockton also monitors ambient water quality to assess potential effects of discharges from the Stockton Regional Wastewater Control Facility. Data are collected at five water quality monitoring sites along the San Joaquin River near the Phase 3

Repair Project area. The Mossdale Bridge sampling site at the Interstate 5 crossing over the San Joaquin River is near elements VIcde and VIIb. The Vernalis sampling site is located near the town of Vernalis, just upstream from the Phase 3 Repair Project area. Some of the broad categories that are monitored are discussed briefly below.

HABITAT

Dense riparian forests once flanked the San Joaquin River in this area. In contrast, the habitat today consists of linear areas and occasional remnant patches of riparian forests and related riparian scrub that grow on or adjacent to the levee, primarily on the waterside. A few larger areas of these riparian forests are present where the river turns away from the levee and creates a point bar and an upland floodplain area. Riprap or large boulders cover the lower half of most of the waterside of the San Joaquin River east levee in the Phase 3 Repair Project area, and ruderal vegetation grows in open areas, especially upslope from the riprap and on large open areas on the landside of the levee. Other areas of levee on the waterside are barren and/or covered with stumps and dead vegetation, likely because of levee maintenance that has included cutting scrub and low vegetation, burning, and applying herbicide. Some of the lands on the waterside of the levee are privately held and are affected by grazing and other landowner activities.

The landside reaches of the Phase 3 Repair Project area levees primarily are barren or covered with ruderal vegetation. Beyond the base of the levees, riparian vegetation is rare but occasionally is present in small, isolated patches. Other trees include occasional single or isolated stands of native oaks and nonnative trees that have been planted around farms, agricultural fields, and residential or other types of development. Habitat and land cover types present in the Phase 3 Repair Project area include riparian forests, nonnative woodlands, agricultural lands, ruderal and developed areas, and aquatic features (including marsh, wetlands, and ponds) (**Exhibits 13a** through **13c**).

VEGETATION AND LAND COVER

As described below, terrestrial vegetation and land cover types in the Phase 3 Repair Project area and vicinity include Great Valley cottonwood riparian forest (remnant), Great Valley oak riparian forest (remnant), nonnative woodland, agricultural (row crops, orchards, dirt roads, and irrigation ditches), and ruderal and developed (residential housing, parks, boat launch facilities, and roads).

- **Great Valley cottonwood riparian forest:** Remnant patches of Great Valley cottonwood riparian forest in the Phase 3 Repair Project area are dominated by large Fremont cottonwood (*Populus fremontii*) trees and Goodding's willow (*Salix gooddingii*). Most of the otherwise linear or smaller patchy areas of this community lack Fremont cottonwood and are represented by Goodding's willow, red willow (*S. laevigata*), arroyo willow (*S. lasiolepis*), narrow leaved-willow (*S. exigua*), scattered valley oak (*Quercus lobata*), Oregon ash (*Fraxinus* latifolia), and buttonbush (*Cephalanthus occidentalis*). Native ground cover species, found mainly in the larger remnant patches of riparian forest, include California blackberry (*Rubus ursinus*) and wild rose (*Rosa californica*). Common nonnative understory species found in most elements include Himalayan blackberry (*Rubus discolor*) and tree tobacco (*Nicotina glauca*). Most of the Great Valley cottonwood riparian forest community also could be characterized as Great Valley riparian scrub, which does not include Fremont cottonwood and is characterized by a shorter canopy and more uniform structure. This habitat, however, is part of the Great Valley cottonwood riparian forest that was extensive and connected along this entire reach of the San Joaquin River. Therefore, this BA describes all riparian habitat as such. The largest stands of Fremont cottonwood trees in the Phase 3 Repair Project area are present in elements IIIb, IVc, Va, and VIa.1.
- **Great Valley oak riparian forest:** Great Valley oak riparian forest is located in the Phase 3 Repair Project area, occurring only on the landside of the levees. This is a medium to tall (rarely to 100 feet), broadleaved, winter deciduous, closed-canopy riparian forest dominated by valley oak. Understories include scattered Northern California black walnut (*Juglans nigra*) and western sycamore (*Platanus racemosa*) as well as young valley oaks. Understory plants include California rose (*Rosa californica*), blackberry (*Rubus* spp.), and

western poison oak (*Toxicodendron diversilobum*) (Hickman 1993; Holland 1986). Two substantial oak groves of very large, healthy valley oak trees are present on the landside of elements IIIb and IVa and account for most of the Great Valley oak riparian forest. Several groups of smaller valley oak trees and individual valley oaks, scattered along the landside of other Phase 3 Repair Project elements, also contribute to this community.

- **Nonnative woodland:** Along the landside of elements Ie, VIa.1, VIde, and VIIg, nonnative trees have been planted around farms, agricultural fields, and residential or other types of development. These woodlands lack understory vegetation, other than grasses and ruderal vegetation.

- **Agricultural cropland:** Cropland in the Phase 3 Repair Project area is dominated by alfalfa fields, orchards, and row crops, such as tomatoes. Ruderal species grow along the edges of fields and irrigation ditches, some of which contain water and associated aquatic plants. The largest areas of agricultural lands are present in elements Va, VIa.1, and VIcde.

- **Ruderal vegetation:** Ruderal vegetation is characterized by nonnative weedy and sometimes invasive vegetation and nonnative annual grasses. Common weed species include yellow star-thistle (*Centaurea solstitialis*), black mustard (*Brassica nigra*), shortpod mustard (*Hirschfeldia incana*), Italian thistle (*Carduus pycnocephalus*), milk thistle (*Silybum marianum*), and Himalayan blackberry. Common grass species include ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum* ssp. *leporinum*), Bermuda grass (*Cynodon dactylon*), and Johnsongrass (*Sorghum halepense*). The levee slopes are dominated by ruderal vegetation. Large open areas in elements IIIa and IVc also are composed primarily of ruderal vegetation, as are smaller open areas in elements VIcde and VIIe that border roads, parking lots, and agricultural land.

- **Developed areas:** Developed areas in the Phase 3 Repair Project area consist of residential areas bordering elements IVa, IVc, Va and VIa.1, and VIIe; parks located in elements IVc and VIa.2, the latter of which is also a boat launching facility; and ranch houses and related facilities located in or adjacent to elements Ie, IIab, Va, VIa.1, and dryland levee element XI. Vegetation in residential areas and parks consists of turf grasses, landscape trees, and occasional valley oak trees. Ranch lands often contain English walnut trees (*Juglans regia*), a variety of landscaped trees, and occasional native valley oak trees.

AQUATIC HABITATS

The principal surface water bodies associated with the Phase 3 Repair Project area are the San Joaquin River and Walthall Slough. Project elements Ia through IVc are located downstream from the confluence of the San Joaquin River and Old River. Reach V is located directly adjacent to this confluence. Elements VIa.1 through VIIe are upstream from the confluence of the San Joaquin River and Old River. Small portions of elements VIIe and VIIg are located along Walthall Slough. An approximately 3.5-acre constructed pond is located adjacent to elements IIab, but outside the project footprint (**Exhibit 13a**).

In the Phase 3 Repair Project area, the San Joaquin River is characterized as a wide channel (approximately 300 feet) with little riparian canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. Altered flow regimes, flood risk management, and bank protection efforts along much of the San Joaquin River have reduced riparian vegetation and associated shaded riverine aquatic (SRA) habitat, sediment transport, channel migration and avulsion, and large woody debris recruitment, and have isolated the channel from its floodplain. This has resulted in a decline in habitat quality for fish species using the San Joaquin River near the Phase 3 Repair Project area. However, fish use this segment of the river, even if only as a migratory pathway to and from upstream spawning and rearing areas.

Wetland vegetation in the Phase 3 Repair Project area is limited to coastal and valley freshwater marshes, several agricultural ditches, and the edges of one constructed pond. Freshwater marsh is isolated in a depression on the landside of the levee in element Ib between Howard Road to the north and a dirt farm road on the south. A limited

amount of freshwater marsh also is present around the edges of a constructed pond, located on a large private estate and equestrian center, east of the Phase 3 Repair Project area levee in element IIab. A second area of freshwater marsh is located just outside the Phase 3 Repair Project area in element Va, and in an area of backwater on the San Joaquin River. Agricultural ditches are located along the edges of fields and orchards.

FISH POPULATIONS

The lower San Joaquin River and Delta serve as a migration corridor and/or provide other types of habitat (e.g., rearing, spawning) for steelhead, delta smelt, white sturgeon (*Acipenser transmontanus*), and green sturgeon. Numerous other resident native and nonnative species also are found in the San Joaquin River. Among the native species present in the river are blackfish (*Orthodon microlepidotus*), threespine stickleback (*Gasterosteus aculeatus*), and San Joaquin roach (*Lavinia symmetricus* sp.); while nonnative species include striped bass (*Morone saxatilis*), white catfish (*Ameiurus catus*), and bluegill (*Lepomis macrochirus*). In late 2014, experimental populations of spring-run Chinook salmon began to be reintroduced to the San Joaquin River, as a component of the SJRRP (see “San Joaquin River” subsection above).

The small, unnamed pond in elements IIab (**Exhibit 13a**) may contain fish and other aquatic species. Because of its isolated nature and size, this pond likely supports only nonnative warm-water fish that probably have been introduced. Typical fish that are found in similar ponds include bluegill, western mosquitofish (*Gambusia affinis*), and catfish (*Ameiurus* or *Ictalurus* spp.), among other nonnative warm-water species.

WILDLIFE

Common wildlife species expected in the Phase 3 Repair Project area are those typically associated with agriculture (e.g., alfalfa, row crops, and orchards) and ruderal habitat, which account for 57 percent of the Phase 3 Repair Project area’s footprint. Species include California ground squirrel (*Spermophilus beecheyi*), Botta’s pocket gopher (*Thomomys bottae*), western harvest mouse (*Reithrodontomys megalotis*), and California meadow vole (*Microtus californicus*). These small mammals are prey for a variety of raptor species known to occur in the area, including Swainson’s hawk (*Buteo swainsoni*). Riparian habitats in the Phase 3 Repair Project area provide nesting habitat for a wide variety of bird species.

SPECIES ACCOUNTS

This section presents species accounts for the federally listed species considered in this BA, including relevant life history and habitat use, as well as the species' potential for occurrence in the action area. The action area (see the "Action Area" section above) encompasses the entire area that may be affected by the Phase 3 Repair Project, including more distant locations where indirect effects may occur. However, the species accounts below focus on the habitat present in the Phase 3 Repair Project area itself and describe the potential for federally listed species to occur in the general vicinity. Only when the habitat quality or species distribution is specifically known for the action area is it described.

VALLEY ELDERBERRY LONGHORN BEETLE

VELB has four life stages: egg, larva, pupa, and adult. This species, which is federally listed as threatened, is nearly always found on or close to its host plant, the elderberry (*Sambucus* sp.). Females lay their eggs on the bark, and larvae hatch and burrow into the stems. The larval stage can last 2 years, after which the larvae enter the pupal stage and transform into adults. Adults are active (feeding and mating) from March to June (USFWS 2006). It appears that to function as VELB habitat, host elderberry shrubs must have stems that are 1.0 inch or greater in diameter at ground level. Use of the plants by the beetle rarely is apparent. Frequently, the only exterior evidence of the shrub's use by the beetle is an oval exit hole, created by the larva just before the pupal stage. Field studies conducted along the Cosumnes River and in the Folsom Lake area suggest that larval galleries can be found in elderberry stems with no evidence of exit holes, because the larvae either succumb before constructing an exit hole or are not far enough along in the developmental process to construct an exit hole (USFWS 1996a).

VELB is patchily distributed throughout the remaining riparian forests of the Central Valley, from Redding to Bakersfield, and appears to be only locally common (i.e., found in population clusters that are not evenly distributed across the Central Valley). Extensive loss of Central Valley riparian forests has occurred since 1900, with riparian forests declining by 80 to 96 percent, depending on the region (USFWS 2006). Although it is wide-ranging, VELB is thought to have suffered a long-term decline because of human activities that have caused widespread alteration and fragmentation of riparian habitats and, to a lesser extent, upland habitats that support the beetle. Low density and limited dispersal capability may cause the beetle to be particularly vulnerable to population isolation because of habitat fragmentation. Insecticide and herbicide use in agricultural areas and along road rights-of-way may be factors limiting the beetle's distribution. The age and quality of individual elderberry shrubs/trees and stands as a food plant for beetle may be a factor in its limited distribution.

Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Repair Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Repair Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat. See **Exhibit 14** for locations of the elderberry shrubs that were observed within 100 feet of the Phase 3 Repair Project area during field surveys in 2014.

CRITICAL HABITAT

Critical habitat for VELB was designated at the time of listing. Two areas along the American River in the Sacramento metropolitan area were designated as critical habitat for this species. The Phase 3 Repair Project area is not located within designated critical habitat for VELB.

RECOVERY PLAN FOR VALLEY ELDERBERRY LONGHORN BEETLE

The Recovery Plan for Valley Elderberry Longhorn Beetle (USFWS 1984) lacks specific goals and does not include objective, measurable recovery criteria (USFWS 2006). The recovery plan identified additional essential habitat for this species in an area along Putah Creek, Solano County, and an area along the American River Parkway, Sacramento County. USFWS released a 5-year status review for VELB on October 2, 2006 (USFWS 2006). This review reported an increase in known beetle locations, from 10 at the time of listing in 1980 to 190 in 2006. Because of the presumed increase in the estimated population and the concurrent protection and restoration of several thousand acres of riparian habitat suitable for VELB, USFWS's status review determined that this species is no longer in danger of extinction and recommended that the species no longer be listed under the ESA. On October 2, 2012, the USFWS issued a proposed rule to delist VELB (78 FR 66058); however, on September 17, 2014, the USFWS withdrew this proposal, stating that the scientific information and analysis reflected in the October 2012 proposal was not strong enough to support a decision to delist the species (79 FR 55874).

RIPARIAN BRUSH RABBIT

Riparian brush rabbit, which is federally listed as endangered, inhabits riparian communities in the northern San Joaquin Valley that are dominated by thickets of willows and large clumps of shrubs and vines, such as wild rose, blackberries, coyote bush, and wild grape. Historically, riparian brush rabbit inhabited dense, brushy areas of valley riparian forests, marked by extensive thickets of wild rose, blackberries, and willows (Sandoval et al. 2006).

Suitable habitat for riparian brush rabbit is characterized by an abundance of woody ground litter, mats of low-growing vines and shrubs, and areas of higher ground not subject to regular or heavy flooding (Sandoval et al. 2006). On a seasonal basis, it also may use dense, tall stands of herbaceous plants adjacent to patches of riparian shrubs (Williams and Hamilton 2002). It tends to avoid large openings in the understory cover, frequenting only small clearings in the vegetation while foraging (USFWS 1998). An essential component of habitat for riparian brush rabbit is high-ground refugia from flooding, which provides protection from predators and dry habitat during prolonged rainstorms (USFWS 1998).

The only known populations of riparian brush rabbit are confined to Caswell Memorial State Park on the Stanislaus River in Stanislaus County, approximately 10 miles southeast of the Phase 3 Repair Project area, and in the South Delta along the San Joaquin River and overflow channels (Williams and Hamilton 2002; Williams et al. 2002; Lloyd and Williams 2003; Vincent-Williams et al. 2004; CDFW 2014) (**Exhibit 15**). The population in the South Delta is found in Paradise Cut along the rights-of-way of the two railroads that cross Paradise Cut and Tom Paine Slough, and in an oxbow on the San Joaquin River near Mossdale Landing (CDFW 2014). Riparian brush rabbits also have been found along the San Joaquin River north of the oxbow population, in waterside riparian habitat near the Phase 3 Repair Project area adjacent to elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1, and VIa.4 (CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004) (**Exhibit 15**). Other historical habitats along the San Joaquin River and tributaries are believed to no longer be suitable for riparian brush rabbits because of irrigated agriculture, livestock grazing, and impoundment and channelization of streams. High-ground refugia also may be lacking in these areas (Williams and Hamilton 2002).

In Paradise Cut, existing habitat for riparian brush rabbits is confined to levee bases, the channel banks of Paradise Cut, and pockets of low ground along the bottom of Paradise Cut. Generally, areas of suitable habitat in these locations are very narrow (15 to 100 feet wide). Most of the channels in Paradise Cut are in effect dead-end sloughs fed by Old River, with large portions containing water year-round, which results in the isolation of some upland areas (i.e., islands). The existing habitat for rabbits is covered in water on average once every 4 years, when flood flows in the San Joaquin River are sufficient to overtop Paradise Weir. Brush rabbits probably use the UPRR right-of-way as high-ground refugia during flooding events (Williams and Hamilton 2002).

Occupied habitat for riparian brush rabbit is documented adjacent to the Phase 3 Repair Project area along the waterside levee in elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1, and VIa.4. The waterside habitat along elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The waterside habitat between elements IIab and IIIa is dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The waterside habitat between elements VIa.1 and VIa.4 is on an oxbow with dense riparian vegetation. Other patches of riparian vegetation along the San Joaquin River and adjacent to Phase 3 Repair Project area levees, such as the Great Valley cottonwood forest and Great Valley oak riparian forest communities shown in **Exhibits 13a** through **13c**, provide potentially suitable habitat for riparian brush rabbit, including the small areas of riparian habitat that are present on the waterside of Phase 3 Repair Project area elements IIab, IVc, and Va.

Riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover rather than in large openings. It feeds on herbaceous vegetation, such as grasses, sedges, clover, forbs, and buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). This species has a small home range and mainly remains hidden under protective shrub cover, seldom venturing more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.

CRITICAL HABITAT

Critical habitat has not been designated for riparian brush rabbit.

RECOVERY PLAN FOR RIPARIAN BRUSH RABBIT

The Recovery Plan for Upland Species of the San Joaquin Valley, California addresses the riparian brush rabbit (USFWS 1998). At the time the recovery plan was prepared, only the Caswell Memorial State Park population was known to exist. One of the most important conservation actions identified in the plan was establishment of other viable populations within the park's range. The recovery plan recommended the following actions (USFWS 1998):

- Initiate a reintroduction program that includes researching genetic diversity among remaining individuals.
- Implement a captive breeding program to translocate individuals to new populations.
- Establish at least three additional wild populations in the San Joaquin Valley in restored and expanded suitable habitat within the rabbit's historical range.

In 1999, the Endangered Species Recovery Program began implementing the Controlled Propagation and Reintroduction Plan for the Riparian Brush Rabbit (Williams et al. 2002), which was recommended in the Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998). The primary goal of the program is to prevent extinction by providing animals for reintroduction to establish new populations or augment existing populations. In July 2002, captive-bred rabbits were released at the San Luis National Wildlife Refuge, near Los Banos in the central San Joaquin Valley, and in 2005, a population of captive-bred rabbits was introduced to a private ranch along the San Joaquin River in Stanislaus County, adjacent to the San Joaquin River National Wildlife Refuge (USFWS 2007). This effort is ongoing.

DELTA SMELT

Delta smelt was formally listed as threatened under the ESA on March 5, 1993 (59 FR 440). On December 19, 1994 (59 FR 65256), USWFS designated critical habitat. Delta smelt is found only from Suisun Bay upstream through the Sacramento–San Joaquin estuary in Contra Costa, Sacramento, San Joaquin, Solano, and Yolo counties.

Delta smelt is endemic to the upper Sacramento–San Joaquin River estuary and occurs primarily in open surface waters of Suisun Bay, in the Sacramento River downstream from Isleton, and in the San Joaquin River downstream from Mossdale (Bennett 2005), including the project area. Its historic range is thought to have extended from Suisun Bay upstream to at least the city of Sacramento on the Sacramento River and Mossdale on the San Joaquin River. Delta smelt historically was one of the most common pelagic fish (fish living in open water away from the bottom) in the upper Sacramento–San Joaquin estuary (USFWS 2004). The delta smelt population generally is concentrated in the estuary west of the confluence of the Sacramento and San Joaquin rivers in high-outflow years and in the north Delta in low-outflow years (Sweetnam 1997, 1998; Bennett 2005). Delta outflow determines the location of the salinity gradient and may strongly influence delta smelt distribution. USFWS data indicate that delta smelt is found in the San Francisco Bay/Sacramento–San Joaquin Delta (Bay-Delta) estuary where salinity generally is less than two parts per thousand. Except when spawning in freshwater, delta smelt most frequently is caught in or is slightly upstream from the entrapment zone (Bennett 2005). In the CDFW Delta-wide 20mm delta smelt survey, delta smelt larvae were observed only occasionally and in very low abundance in the vicinity of the project area (less than four larvae in 10,000 cubic meters as sampled on April 4, 2014). The species was not observed in the project vicinity in 2015 or 2016, during the delta smelt monitoring program that occurs from January through March.

CRITICAL HABITAT

Although the Phase 3 Repair Project area is near the upper limit of the known distribution of delta smelt, it is included in the area designated as critical habitat for the species (Critical Habitat Determination for the Delta Smelt, 59 FR 65256, December 19, 1994). In the critical-habitat designation, USFWS identified the following primary constituent elements essential to conservation of delta smelt: physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration (59 FR 65256). The primary constituent elements are organized by habitat conditions required for each life stage. USFWS has identified specific areas in the Delta for spawning habitat, larval and juvenile transport, and adult migration for delta smelt. The Phase 3 Repair Project area and larger action area include places identified for larval and juvenile transport and adult migration, but do not include specific areas important for delta smelt spawning habitat (59 FR 65256).

RECOVERY PLAN FOR DELTA SMELT

The Sacramento–San Joaquin Delta Native Fishes Recovery Plan includes restoration of abundance and distribution of delta smelt (USFWS 1996b). Action items in the recovery plan for delta smelt refer to four zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of delta smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Repair Project area or action area.

LONGFIN SMELT

On April 2, 2012, the USFWS issued its finding that the longfin smelt warranted protection under the ESA, and added it as a candidate species for protection under the ESA (77 FR 19755). Longfin smelt is found in bay, estuarine, and nearshore coastal environments from San Francisco Bay north to Lake Earl near the Oregon border. The southernmost detection of the species was a single fish from Monterey Bay (Eschmeyer et al. 1983), although

spawning has not been documented south of San Francisco Bay. The San Francisco estuary and the Delta support the largest longfin smelt population in California. Longfin smelt is more broadly distributed throughout the Bay-Delta estuary and is found in water with higher salinities than delta smelt. Longfin smelt most often is concentrated in Suisun Bay, San Pablo Bay, and northern San Francisco Bay during nonspawning periods (Moyle 2002). No fish surveys have been conducted by RD 17 within the river stretch adjacent to the Phase 3 Repair Project area; however, CDFW's Delta-wide sampling program, including the 20mm delta smelt survey, longfin smelt larva survey, summer tow net survey, and spring Kodiak Trawl sampling, occurs in the vicinity of this area. Longfin smelt has a short life span, generally reaching maturity at 2 years of age, when it spawns and then dies. During the second year of life, adults tend to inhabit the higher salinity western portion of the estuary system; they occasionally have been found in nearshore ocean surveys (Rosenfield and Baxter 2007). Adults spend their lives in bays, estuaries, and nearshore coastal areas, and migrate into low-salinity or freshwater reaches of coastal rivers and tributary streams to spawn. Spawning occurs in the lower portions of the Sacramento and San Joaquin rivers and adjacent sloughs, typically between November and June, with peak spawning occurring from February through April (Baxter 1999; DWR 2009; Moyle 2002; Wang 1986). On the San Joaquin River, spawning occurs downstream from Medford Island, approximately 20 miles downstream from the project site (Moyle 2002). Locations and movements of all life stages of longfin smelt are influenced by a wide range of hydrologic and environmental variables (Rosenfield 2010), all of which show high variation among and within years; accordingly, temporal and spatial distributions of longfin smelt show high variation among and within years.

Critical Habitat

Because the longfin smelt has not been listed, no critical habitat has been designated.

Recovery Plan for Longfin Smelt

The Sacramento–San Joaquin Delta Native Fishes Recovery Plan includes restoration of abundance and distribution of longfin smelt (USFWS 1996b). Action items in the recovery plan for longfin smelt refer to five zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of longfin smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Repair Project area or action area.

CENTRAL VALLEY STEELHEAD DISTINCT POPULATION SEGMENT

On March 19, 1998, NMFS listed the Central Valley steelhead DPS as threatened (63 FR 13347). Central Valley steelhead DPS is considered to be winter-run steelhead (McEwan and Jackson 1996). In the most recent 5-year review of the listing of this species, NMFS recommended that the Central Valley steelhead DPS should remain classified as a threatened species (NMFS 2011a). Findings of the next 5-year status review for all federally listed anadromous salmonids in the Central Valley are anticipated to be published in 2016. Like other anadromous salmonid species, this one matures in the ocean before entering freshwater on its spawning migrations. The major factor influencing steelhead populations in the San Joaquin River system is loss of habitat caused by construction of impassable dams on the mainstem and major tributaries.

Historically, Central Valley steelhead was found throughout the Sacramento and San Joaquin drainages, where waterways were accessible to migrating fish. Steelhead historically was present in the upper San Joaquin River basin, upstream from the current location of Friant Dam. Steelhead commonly migrated far up tributaries and into headwater streams where cool, well-oxygenated waters were present year-round.

Currently, in the Central Valley, viable populations of naturally produced steelhead are found only in the Sacramento River and its tributaries. Wild steelhead populations appear to be restricted to tributaries of the Sacramento River below Keswick Dam, such as Antelope, Deer, and Mill Creeks, and to the Yuba River below Englebright Dam (McEwan and Jackson 1996). No significant populations of steelhead remain in the San Joaquin

River basin; however, small persistent runs still occur on the Stanislaus and Tuolumne rivers, and perhaps the Merced River (McEwan and Jackson 1996).

Juvenile steelhead rear throughout the year and may spend 1 to 3 years in freshwater before emigrating to the ocean. Smoltification, the physiological adaptation that juvenile salmonids undergo to tolerate saline waters, occurs in juveniles as they begin their downstream migration. Smolting steelhead (age class 1+ and older) generally emigrate from March to June (Barnhart 1986; Reynolds et al. 1993).

The San Joaquin River near the Phase 3 Repair Project area is used by adult and juvenile steelhead primarily as a migration corridor between the ocean and cold-water habitat in the upstream tributaries. Juvenile steelhead would be likely to use the edges of rivers and sloughs, and floodplain habitats, if available, for rearing as they emigrate (Moyle 2002).

CRITICAL HABITAT

Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins. The Phase 3 Repair Project area is located within designated critical habitat for the Central Valley steelhead DPS.

RECOVERY PLAN FOR CENTRAL VALLEY STEELHEAD DISTINCT POPULATION SEGMENT

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Although habitat conditions for Central Valley steelhead have improved slightly over the past decade, access to historic habitat generally remains blocked, and the quality of the species' remaining habitat generally remains degraded (Lindley et al. 2009; Cummins et al. 2008).

CENTRAL VALLEY FALL/LATE FALL-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

On September 16, 1999 (64 FR 50393), NMFS determined that listing was not warranted for the Central Valley fall/late fall–run Chinook salmon ESU; however, the ESU was designated as a future candidate for listing because of concerns about specific risk factors. On April 14, 2004 (69 FR 19975), the ESU was reclassified as a species of concern. The ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin River basins and their tributaries, east of the Carquinez Strait. The Central Valley fall/late fall–run Chinook salmon ESU currently is the only run of Chinook salmon in the San Joaquin River system.

Adult Central Valley fall/late fall–run Chinook salmon enter the Sacramento and San Joaquin river systems from September through January and spawn from October through February. In general, San Joaquin River populations tend to mature at an earlier age and spawn later in the year than Sacramento River populations (Baker and Morhardt 2001). These differences may be phenotypic responses to the generally warmer temperature and lower flow conditions found in the San Joaquin River basin, relative to the Sacramento River basin.

Juveniles typically rear in freshwater for 3 to 6 months (fall-run) and up to 12 months (late fall–run) before entering the ocean. Juveniles migrate downstream from January through June. Juvenile Chinook salmon prefer water depths of 0.5 foot to 3.3 feet and velocities of 0.26 foot to 1.64 feet per second (Raleigh et al. 1986). Important winter habitat for juvenile Chinook salmon includes flooded bars, side channels, and overbank areas with relatively low water velocities. Juvenile Chinook salmon have been found to rear successfully in floodplain habitat, which routinely floods but is dry at other times. Growth rates appear to be enhanced by the conditions found in floodplain habitat (Sommer et al. 2001).

Cover structures, space, and food are necessary components for Chinook salmon rearing habitat. Suitable habitat includes areas with instream and overhead cover in the form of undercut banks, downed trees, and large, overhanging tree branches. The organic materials forming fish cover also help provide sources of food, in the form of both aquatic and terrestrial insects.

Fall-run Chinook salmon adults primarily pass through the Phase 3 Repair Project area on their way to spawn in upstream tributaries of the San Joaquin River (Moyle 2002). Juvenile fall-run Chinook salmon emigrate from San Joaquin River tributaries (e.g., the Stanislaus, Merced, and Tuolumne rivers) and other river tributaries through the San Joaquin River during the late winter and spring (February through mid-June) (San Joaquin River Group Authority 2009). Juvenile Chinook salmon use the edges of rivers and sloughs for rearing as they emigrate downstream (Moyle 2002).

CRITICAL HABITAT

No critical habitat has been designated for Central Valley fall/late fall-run Chinook salmon.

ESSENTIAL FISH HABITAT

EFH has been designated for Pacific Salmon. This includes identification of Chinook salmon EFH, which occurs in the project and action areas. Central Valley fall/late fall-run Chinook salmon ESU is in the Phase 3 Repair Project area along the San Joaquin River. EFH includes migration, holding, and rearing habitat and opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014a).

Construction of element IVc would improve EFH, by providing the type of refuge habitat for juvenile salmonids during high-water flows as described in Amendment 18 for the lower San Joaquin River tributaries (NMFS 2014c).

RECOVERY PLAN FOR CENTRAL VALLEY FALL/LATE FALL–RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

Although the Central Valley fall/late fall-run Chinook salmon is not listed as threatened or endangered under the ESA, the Sacramento–San Joaquin Delta Native Fishes Recovery Plan outlines conservation measures and restoration objectives and criteria for the species, including the San Joaquin River run, which CDFW recognizes as a distinct stock (USFWS 1996b). Reasons for decline identified by the plan include habitat loss, suitability of habitat, survival of outmigrants, harvest, hatcheries, and water quality. Conservation measures include:

- testing an electrical fish barrier and a physical barrier upstream from the confluence of the Merced River to prevent adult fish from straying,
- constructing and rehabilitating spawning riffles,
- constructing a temporary barrier at Old River to prevent entrainment of outmigrating smolts, and when possible,
- coordinating water releases to provide attraction or outmigration flows.

These efforts have been funded by a wide range of federal, State, and private agencies (USFWS 1996b).

SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

The Sacramento River winter-run Chinook salmon was formally listed as threatened in November 1990 (55 FR 46515), and was reclassified as endangered under the ESA on January 4, 1994 (59 FR 440).

In the Delta, winter-run adults begin to move through the system in early winter (November–December), with the first upstream adult migrants appearing in the upper Sacramento River during late December (Vogel and Marine 1991, cited in NMFS 2003). Adult winter-run presence in the upper Sacramento River system peaks in March. The timing of migration may vary somewhat because of changes in river flows, dam operations, and water year type. Spawning occurs primarily from mid-April to mid-August, with peak activity occurring in May and June in the river reach between Keswick Dam and the Red Bluff Diversion Dam (Vogel and Marine 1991, cited in NMFS 2003).

Juvenile winter-run Chinook salmon occur in the Delta from October through early May, based on data collected from trawls, beach seines, and salvage records at State and federal water projects (DFG 1998). The peak of juvenile arrivals is between January and March. Juveniles tend to rear in the freshwater upper Delta areas for about the first 2 months (Kjelson et al. 1981, 1982). As they mature, winter-run Chinook fry and fingerlings prefer to rear farther downstream, where ambient salinity is up to 1.5 to 2.5 parts per thousand (Healey 1980, 1982; Levings et al. 1986). Fry remain in the estuary until they reach a fork length of about 118 millimeters (i.e., at 5 to 10 months of age). Emigration from the Delta may begin as early as November and continue through May (Fisher 1994; Myers et al. 1998).

With the exception of occasional strays, adult winter-run Chinook salmon generally do not occur in the San Joaquin River or in this portion of the Delta, and therefore, do not occur in the action area. The same is true for juvenile winter-run Chinook salmon.

CRITICAL HABITAT

Critical habitat for the winter-run Chinook salmon ESU was designated by NMFS on June 16, 1993 (58 FR 33212), with an effective date of July 16, 1993. Critical habitat is designated to include the Sacramento River from Keswick Dam (River Mile 302) to Chipps Island (River Mile 0) and all waters westward, including San Francisco Bay north of the Bay Bridge to the Golden Gate Bridge. The proposed action is not within designated critical habitat.

ESSENTIAL FISH HABITAT

EFH for Chinook salmon, which includes Sacramento River winter-run Chinook salmon ESU (NMFS 2014a), has been identified in the project and action areas. See the "Essential Fish Habitat" section of this BA.

RECOVERY PLAN FOR SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. In essence, improvement in the status of winter-run Chinook salmon ESU depends on re-establishment of an alternate population in a historically used area (e.g., Battle Creek) (Williams et al. 2011). Improvement of spring-run Chinook salmon ESU is dependent on improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects also are of primary importance in improving the status of this ESU (NMFS 2014b).

Recovery goals and restoration actions for Sacramento River winter-run Chinook salmon ESU are described by Williams et al. (2011) for the Sacramento River basin, including re-establishment of a population in a historically used area (e.g., Battle Creek) and fish passage improvement projects. Recovery goals do not, however, apply to the action area, because reintroduction of winter-run Chinook salmon is not planned for the San Joaquin River Basin.

CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

NMFS listed Central Valley spring-run Chinook salmon as threatened on September 16, 1999 (50 FR 50394).

Central Valley spring-run Chinook salmon historically was the most abundant run of Central Valley Chinook salmon (Fisher 1994). It occupied the headwaters of all major river systems in the Central Valley, where no natural barriers existed. Adults returning to spawn ascended the tributaries to the upper Sacramento River, including the Pit, McCloud, and Little Sacramento rivers. They also occupied Cottonwood, Battle, Antelope, Mill, Deer, Stony, Big Chico, and Butte creeks and the Feather, Yuba, American, Mokelumne, Stanislaus, Tuolumne, Merced, San Joaquin, and Kings rivers. Spring-run Chinook salmon migrated farther into headwater streams, where cool, well-oxygenated water was available year-round.

Surveys indicate that populations of remnant, non-sustaining spring-run Chinook salmon may be found in Cottonwood, Battle, Antelope, and Big Chico creeks (DWR 1997); more sizable, consistent runs of naturally produced fish are found only in Mill, Deer, and Butte creeks (Williams et al. 2011). All these creeks are tributaries in the Sacramento River basin. The Feather River Fish Hatchery sustains the spring-run population on the Feather River, but the genetic integrity of that run is questionable (DWR 1997). Although all of these populations are found in the Sacramento River basin, the ESU boundary of Central Valley spring-run Chinook salmon includes populations spawning in the Sacramento River and San Joaquin River basins, as reflected in the current 5-year status review (Williams et al. 2011; NMFS 2011b). The status of Central Valley spring-run Chinook salmon ESU likely has not improved since the 2005 status review (Williams et al. 2011). Improvement of spring-run Chinook salmon ESU is dependent on improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects also are of primary importance in improving the status of this ESU (NMFS 2014a). Current and future efforts to restore production in the San Joaquin River are either being planned or are just beginning, and no results about their current efficacy are available.

Like winter-run Chinook salmon, adult spring-run Chinook salmon (other than occasional strays) generally have not occurred in the San Joaquin River basin, and therefore, do not occur in the action area. The same is true for juvenile spring-run Chinook salmon.

CRITICAL HABITAT

Critical habitat for the Central Valley spring-run Chinook salmon was designated on August 12, 2005; a final designation was published on September 2, 2005, with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include selected waters in the Sacramento River basin from approximately Redding (River Mile 302) to approximately Chipps Island (River Mile 0) at the westward margin of the Delta and includes the Sacramento River. The Phase 3 Repair Project area is located outside the species' designated critical habitat.

ESSENTIAL FISH HABITAT

EFH for Chinook salmon, which includes Central Valley spring-run Chinook salmon ESU (NMFS 2014a), has been identified in the project and action areas. See the " Essential Fish Habitat" section of this BA.

RECOVERY PLAN FOR CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Recovery goals and restoration actions are outlined for the Sacramento River basin and do not apply to the action area.

As discussed above in the "San Joaquin River" subsection of the "Environmental Baseline" section, one of the goals of the SJRRP is "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish" (Reclamation and DWR 2011). The Settlement stipulates reintroduction of spring-run and fall-run Chinook salmon, with a priority given to restoring self-sustaining populations of wild spring-run Chinook salmon.

NORTH AMERICAN GREEN STURGEON DISTINCT POPULATION SEGMENT

On April 7, 2006, NMFS listed the Southern DPS of the North American green sturgeon as threatened under the ESA. In North America, green sturgeon is found from Ensenada, Mexico to southeast Alaska. The Southern DPS includes individual reproductive populations south of the Eel River. The populations north of the Eel River, grouped as the Northern DPS, currently do not warrant listing.

Green sturgeon is found in the lower reaches of large rivers, including the Sacramento–San Joaquin River basin, and in the Eel, Mad, Klamath, and Smith rivers. Green sturgeon adults and juveniles are found throughout the upper Sacramento River, as indicated by observations incidental to winter-run Chinook monitoring at Red Bluff Diversion Dam in Tehama County (Poytress et al. 2013; NMFS 2005). Green sturgeon spawns predominantly in the upper Sacramento River and is found primarily in the mainstem Sacramento River.

The green sturgeon is a primitive, bottom-dwelling fish, characterized by its large size (up to 7 feet long and 350 pounds), with a long, round body and "scutes" or plates along its dorsal and lateral sides. It is known to migrate up to 600 miles between freshwater and salt water environments and commercially is caught in the Columbia River and coastal Washington (PFMC 2003). Like all sturgeon species, it is anadromous, but it also is the most marine-oriented of the sturgeon species (NMFS 2005). It spends most of its life in salt water and returns to spawn in freshwater. Individuals congregate in the bays of these systems in summer, while some may travel upstream to spawn in spring and summer. Adult Southern DPS green sturgeon enter San Francisco Bay in late winter through early spring and spawn from April through early July, depending on water flow and temperature (Heublein et al. 2009).

The Southern DPS of the North American green sturgeon is slow growing and late maturing, reaching sexual maturity at about 15 years, at a length of about 5 feet, and typically spawning every 3 to 4 years (NMFS 2015). Green sturgeon spawning has been documented only in the Klamath, Sacramento, and Rogue rivers during recent times (NMFS 2005), although a spawning event was documented in 2011 in the lower Feather River at the Thermalito Afterbay Outlet (Seesholtz et al. 2014). Green sturgeon spawning in the San Joaquin River is not documented, as reported in the 5-year species status review for the Southern DPS of the North American green sturgeon (NMFS 2015).

Green sturgeon populations in the Southern DPS have relatively small population sizes, potentially have lethal temperature limits, face entrainment by water projects and influences of toxic material and exotic species, and may be susceptible to catastrophic events. Impassable barriers to spawning grounds are an additional threat. Preliminary Southern DPS population size estimates are being provided from Dual Frequency Identification Sonar surveys of aggregating sites in the upper Sacramento River; surveys conducted between 2010 and 2014 indicated an annual range of 164 to 526 spawning adults (personal communication with Ethan Mora, UC Davis, March 30, 2015, reported in NMFS 2015). Based on an estimate of mean spawning periodicity, as many as 1,348 ± 524 adults are estimated in the Southern DPS (personal communication with Ethan Mora, UC Davis, May 6, 2015, reported in NMFS 2015).

Green sturgeon may occur in the San Joaquin River between Stockton and the Highway 140 bridge (IEP 2013), including in the Phase 3 Repair Project area, although no evidence exists of historical use of the San Joaquin River by green sturgeon (BRT 2005; Beamesderfer et al. 2007). No documentation is known for green sturgeon spawning in the San Joaquin River, but spawning may have occurred before construction of large-scale hydropower and irrigation development (Mora et al. 2009). White sturgeon persist in the San Joaquin River at population levels of 10 percent of Sacramento River population levels. Young green sturgeon have been taken occasionally in the Santa Clara Shoal area in the Delta, but these fish likely originated in the Sacramento River (NMFS 2005).

CRITICAL HABITAT

Critical habitat for Southern DPS of North American green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

RECOVERY PLAN FOR NORTH AMERICAN GREEN STURGEON DISTINCT POPULATION SEGMENT

A recovery plan has not been developed for green sturgeon, but the Federal Recovery Outline for the Southern DPS of the North American green sturgeon is available (NMFS 2010).

DIRECT AND INDIRECT EFFECTS ON SPECIES IN THE ACTION AREA

Under the ESA, direct effects are those that are caused by the project and occur at the same time as the action (e.g., construction-related effects). Indirect effects are those that are caused by the proposed action and are later in time but are reasonably certain to occur and there is a causal relationship with the action (e.g., operational effects). In other words, there is a logical, unbroken, traceable, explainable, predictable, chain of effects that results in, or "causes" a given effect on listed species. Avoidance and minimization measures for both direct and indirect effects are presented in the "Avoidance and Minimization Measures" section above. This section includes an evaluation of direct and indirect effects related to both the Phase 3 Repair Project (see "Effects Related to the Phase 3 Repair Project Actions" subsection) and the 2017 Emergency Response Construction Project (see "Effects Related to the 2017 Emergency Response Construction Project Actions" subsection).

EFFECTS RELATED TO THE PHASE 3 REPAIR PROJECT ACTIONS

VALLEY ELDERBERRY LONGHORN BEETLE

No known documented occurrences exist of VELB in the Phase 3 Repair Project area, but the species could use elderberry shrubs in the action area. Elderberry shrubs that could support beetles are sparsely scattered throughout the action area, along both the waterside and landside of the San Joaquin River levee.

Eighteen elderberry shrubs are present in or adjacent to the footprint of the Phase 3 Repair Project. The nine elderberry shrubs located along the waterside of the Phase 3 Repair Project levees would be avoided and protected during construction (see "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle"). The nine elderberry shrubs located along the landside of the levee would require removal to accommodate construction of the Phase 3 Repair Project's seepage berms, cutoff walls, and setback levee (**Table 5**; **Exhibit 14**). However, one of these landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

Table 5
Survey Results for Landside Elderberry Shrubs to be Removed from the Phase 3 Repair Project Area

Shrub Number	Number of Stems per Diameter Category (inches)			Beetle Exit Holes Present?	Riparian?
	≥ 1 and ≤ 3	≥ 3 and ≤ 5	≥ 5		
9	0	0	0	No	No
10	73	6	0	No	No
11	25	17	8	No	No
13	12	4	4	No	No
14	5	4	2	No	No
15	32	11	2	No	No
16	13	4	1	No	No
17	25	4	5	No	No
18	6	5	0	No	No
Total	**191**	**55**	**22**		

Notes:
Riparian = waterside of levee; Nonriparian = landside of levee
Source: Data compiled by AECOM in 2014

The eight elderberry shrubs on the landside have a total of 268 stems that are greater than 1 inch in diameter at ground level. These shrubs would require removal during construction of the Phase 3 Repair Project, resulting in direct effects on VELB. If the stems are occupied by beetles, any early-stage individuals are likely to be killed when the shrub is removed. Complete loss of the shrubs to be removed should be avoided by transplanting during the shrubs' dormant season; however, transplanted elderberry shrubs can experience stress or health problems because of changes in soil, hydrology, microclimate, or associated vegetation, and mortality of transplanted shrubs would preclude their future use by the beetle. Removing shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected; alternately, adverse effects on elderberry shrubs could have an overall effect on the beetle, even if larvae are absent at the time of impact, if the shrubs are relied on for reproduction. In addition, it takes 5 or more years for replacement elderberry plantings to reach a size conducive to use as VELB habitat. Therefore, a temporary loss of habitat available to the beetle would occur. The Phase 3 Repair Project would comply with avoidance and minimization measures described for VELB and would compensate for removal of these stems, in accordance with the VELB Guidelines (USFWS 1999). A net reduction in the number of elderberry shrubs would be avoided by requiring establishment of 367 elderberry seedlings and 367 associated native plantings.

Elderberry shrubs that cannot be avoided would be transplanted to the levee setback area in element IVc (**Exhibit 12**). The restoration design, as outlined in the Conceptual MMP (**Appendix E**), would include 367 elderberry seedlings and 367 associated species plantings to compensate for the effects to VELB habitat in the Phase 3 Repair Project area.

After construction of the Phase 3 Repair Project, RD 17 would continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which would include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). Trees only would be trimmed, not removed, under these practices. Therefore, no change would occur in the number of elderberry shrubs along the RD 17 levees.

RIPARIAN BRUSH RABBIT

As shown in **Table 6**, the Phase 3 Repair Project levee improvements would result in the removal of 3.28 acres of landside riparian habitat—specifically Great Valley cottonwood riparian forest and Great Valley oak riparian forest—that is suitable for riparian brush rabbit. This riparian habitat is located on the landside of the levee, where levee improvements (e.g., chimney drains, seepage berms) would be constructed. In general, most of the landside riparian vegetation is sparse and lacks understory vegetation other than grasses and ruderal vegetation, which would act as cover for riparian brush rabbit and would not be suitable for this species (Hansen, pers. comm., 2011). However, potential exists for some of these landside woody habitats to support suitable habitat for riparian brush rabbit, particularly because they are located adjacent to waterside riparian habitats that either are known to be occupied by this species or are highly suitable habitat. All landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied or highly suitable for riparian brush rabbit (i.e., elements IIab through element VIe). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species. No waterside woody or riparian habitat would be removed because of levee improvement activities.

Nearly 54 acres of ruderal annual grassland also would be affected by Phase 3 Repair Project implementation. All effects on ruderal annual grassland that would result from levee improvements are assumed to be temporary because annual grassland would be reestablished in these areas after project completion. Although riparian brush rabbit may use annual grassland as a source for foraging habitat, the key component of habitat suitability for this species in the Phase 3 Repair Project area is based on the presence of riparian woody vegetation and not the surrounding grasslands. Riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover, rather than in large openings, feeding on herbaceous vegetation, such as grasses, sedges, clover, forbs, buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). Furthermore, because this species is known to have a small home range and seldom ventures more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006), the riparian brush rabbit likely uses only a small component of the grassland, and its use of such habitat is concentrated along the edges of the riparian areas.

Table 6
Effects of Implementing the Phase 3 Repair Project on Suitable Riparian Brush Rabbit Habitats

	Acres of Directly Affected Suitable Habitat
Waterside woodlands[1]	0.00
Landside woodlands[1,2]	3.28
Total	**3.28**[3]

Notes:
1. Suitable riparian brush rabbit habitats are characterized as Great Valley cottonwood riparian forest and Great Valley oak riparian forest.
2. Most of the landside riparian vegetation is sparse and lacks understory and is not suitable for this species (Hansen, pers. comm., 2011). However, any landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied by or highly suitable for riparian brush rabbit (i.e., elements IIab through elements VIe). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.
3. Of this, 1.61 acres were removed in elements IIIb, IVa, Va, VIa.1, and VIbcde during implementation of 2017 Emergency Response Construction Project in April 2017.

Source: Data compiled by AECOM in 2014; Updated by GEI Consultants, Inc. 2017

RD 17's ongoing practice for vegetation encroachment management is limited to trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up 5 feet above the ground or 12 feet above the crown road. Thus, trees and shrubs are only trimmed, not removed, because of this maintenance practice. Thus, RD 17's long-term management of vegetation encroachments on the landside and waterside of the levee is not expected to result in reduction or change to existing riparian habitat. The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed because of Phase 3 Repair Project construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed because of Phase 3 Repair Project construction (3.28 acres; see **Table 6**), but none would be removed because of future vegetation management activities.

The loss of potential riparian brush rabbit habitat in the Phase 3 Repair Project area could restrict the range of this species because the RD 17 area currently contains the northernmost known extent of the population on the San Joaquin River. It also could isolate other populations residing in residual habitats in the project vicinity. However, the proposed conservation measures (see the "Avoidance and Minimization Measures" section above) would minimize direct loss of riparian habitat in conjunction with compensation for adverse effects. Implementing such measures is anticipated to avoid a net reduction in the number of riparian brush rabbit and its associated habitat. The Phase 3 Repair Project would include restoration of at least 9.9 acres of riparian scrub habitat and upland refugia in the setback area at element IVc (**Exhibit 12**). The expansion and restoration of riparian habitat in element IVc would augment the waterside riparian corridor along the San Joaquin River and would provide additional riparian habitat opportunities for the riparian brush rabbit between two known occurrences of this species (i.e., between elements IIIa/IIIb and elements VIa.1/VIa.4 [CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). The restored riparian scrub habitat (up to 7.5 acres) would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee would remain in place, and up to 4 acres of Great Valley oak woodland would be established on it, thus providing upland refugia for the riparian brush rabbit during high-water events. The restoration of approximately 9.9 acres (and up to 11.5 acres) of suitable habitat for riparian brush rabbit would achieve a 3:1 restoration to impact mitigation ratio (for effect on potential riparian brush rabbit habitat).

Federally Listed Fish Species

Fish species/ESUs addressed in this BA would likely use similar habitat in the action area. Therefore, the direct and indirect effects on delta smelt, longfin smelt, Central Valley fall/late fall–run Chinook salmon, Central Valley steelhead, and green sturgeon are discussed together. Effects on Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon, which are unlikely to occur in the action area but may occasionally occur as strays, would be similar.

Temporary Construction-Related Effects

The Phase 3 Repair Project would include constructing several cutoff walls, which would entail degrading the top one-third to one-half of the levee, beginning with a 1:1 cut at the waterside crown. Implementing cutoff walls as part of the Phase 3 Repair Project would disturb soils along the top of the levee, which could enter the San Joaquin River through wind and water erosion. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately could be pumped into the San Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff. Waters (1995) evaluated the effects of turbidity and siltation in waterways at various exposure levels. Prolonged exposure to high levels of suspended sediment could create a loss of visual capability in fish, leading to a reduction in feeding and growth rates, and to a thickening of the gill epithelia, which may cause the loss of respiratory function; clogging and abrasion of gill filaments; and increases in stress levels, reducing the tolerance of fish to disease and toxicants (Waters 1995). Also, high levels of suspended sediments could cause the movement and redistribution of fish populations or other aquatic organisms, and could affect physical habitat (Waters 1995). Sediment loading could interfere with photosynthesis of aquatic flora and displace aquatic fauna. Many fish and other aquatic species are sight feeders, and turbid waters would reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, could become disoriented and leave areas where their main food sources are located, ultimately reducing their growth rates. Increased turbidity and sedimentation cause fish to avoid an area, thus reducing available habitat. Fish will not occupy areas unsuitable for survival unless they have no other option. Therefore, construction-related erosion could result in elevated river turbidity in critical species-specific and life stage-specific habitats, potentially precluding a species from occupying that habitat. In addition, the potential would exist for contaminants (such as bentonite slurry, fuels, oils, and other products used in construction) to be introduced into the waterway directly or through surface runoff. Contaminants may be toxic to fish, or may alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival.

Through implementation of the water quality BMPs, including a SWPPP, and BMPs for slurry management and a slurry spill contingency plan, the proposed conservation measures (see the “Avoidance and Minimization Measures” section in this BA) would avoid direct and indirect take of fish during construction. The Phase 3 Repair Project would not be expected to have an effect on the overall continued existence and survival of these species.

Permanent Construction-Related Effects

Most waterside woodlands in the Phase 3 Repair Project area are assumed to provide SRA habitat functions. Apart from the placement of 0.64 acre of riprap above the HTL along the waterside levee along 740 linear feet at element IVc, the Phase 3 Repair Project would not include performing any work on the waterside of the levee, and no waterside woodlands or SRA habitat would be removed. Therefore, construction-related effects on the habitats of federally listed fish species would be limited to minor disturbance of the waterside levee at three locations that are above the HTL and characterized by ruderal vegetation.

RD 17 would continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which would include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). Because vegetation management would be limited to trimming trees, no trees would be removed; thus, no change would occur in the amount of waterside habitat that would be directly affected and removed because of future vegetation management activities.

The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed because of construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed because of Phase 3 Repair Project construction (3.28 acres; see **Table 6**) but none would be removed because of future vegetation management activities.

Because all Phase 3 Repair Project construction activities would occur above the HTL and no SRA habitat would be removed during Phase 3 Repair Project construction or future vegetation management activities, the Phase 3 Repair Project would not result in adverse effects on Central Valley steelhead, Delta smelt, longfin smelt, Sacramento River winter-run and Central Valley fall- and spring-run Chinook salmon, or green sturgeon.

BENEFITS OF PROJECT ACTIONS TO REARING SALMONIDS

Construction of a 1,240-foot-long setback levee with cutoff wall and seepage berm on a major oxbow of the San Joaquin River (see **Table 2**) would directly benefit fish resources. A Conceptual MMP has been prepared to describe the planned expansion and restoration of riparian habitat that would occur in element IVc (**Appendix E**).

Approximately 0.64 acres (740 linear feet) of riprap would be installed on the waterside of the existing levee (above the HTL), where it would intersect the setback levee. After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 5 acres of floodplain to the river. That floodplain area would be graded to allow complete drainage of the floodplain to the river through the downstream opening in the remnant levee, as river flows recede. This would minimize the possibility of fish stranding. The other major benefit to fish resources would be the creation of approximately 5 acres of floodplain rearing habitat for juvenile salmonids, in particular, but also to other native fishes. The seasonal nature of inundation, along with complete drainage, would preclude establishment in the floodplain of predatory, non-native fishes.

The specific elevation of the levee breach invert elevation is under consideration. The primary purpose of the setback levee would be to provide habitat for the riparian brush rabbit. The invert elevation and the floodplain elevation would be based on site constraints, habitat requirements, and balancing the needs of riparian brush rabbit to provide protection to any individuals during high-water events while providing a level of disturbance that would support riparian scrub habitat in a sustainable way. The levee breach invert is expected to be set at an elevation to inundate approximately every 3 to 4 years, and the lower floodplain would inundate approximately every 6 years. A detailed hydraulic analysis of the surface water hydrology anticipated within the levee setback area, based on three possible levee breach invert elevations, is provided in the Conceptual MMP (**Appendix E,** see “Mitigation Site Baseline, Hydrology,” and **Appendix B**). The floodplain habitat would not be permanently inundated and would not be connected to the San Joaquin River during the dry season.

Jeffries et al. (2008) reared juvenile Chinook salmon in enclosures for two consecutive flood seasons within various habitats of the Cosumnes River and its floodplain, to compare fish growth in river channel and floodplain habitats. Significant differences in growth rates were found; salmon reared in seasonally inundated habitats with annual terrestrial vegetation experienced higher growth rates than those reared in a perennial pond on the floodplain. Furthermore, riverine fish growth upstream from the floodplain varied with flow in the river; with little growth and high mortality during high-water events. When stream flows were low and clear, fish growth was rapid. Growth rates were poor in tidally influenced riverine habitat below the floodplain, where juveniles commonly were displaced during high-water events because of a lack of in-channel complexity. Overall, ephemeral floodplain habitats supported higher growth rates for juvenile Chinook salmon than more permanent habitats in either the floodplain or river. Variable responses in both growth and mortality, however, indicate the importance of providing habitat complexity for juvenile salmon in floodplain reaches of streams, so fish can find optimal places for rearing under different flow conditions. Habitat complexity allows juvenile salmon to find cover, thereby reducing the risk of predation from avian and piscine predators. Floodplain and other off-channel habitat restoration are important for improving production of juvenile salmonids in California's Central Valley. Juvenile salmonid emigration generally is passive during high-water events (Healey 1980; Kjelson et al. 1981); they essentially are entrained in the water column until they encounter slower water velocities, where active swimming becomes possible. The San Joaquin River, like most rivers in the Central Valley, is incised and lacks channel complexity. With the exception of the Yolo Bypass for the Sacramento River (Sommer et al. 2001), juvenile salmonids frequently are displaced downstream to the intertidal Delta, where growth is diminished during high-water events in systems that lack access to floodplains. However, protected floodplain habitat provides protection for juvenile salmonids being swept downstream during high-water events.

High San Joaquin River outflows generally occur during winter and early spring months. Juvenile fall/late fall-run Chinook salmon and steelhead outmigration occurs at least partially during this period, while spring-run Chinook salmon and green sturgeon outmigration occurs later.

- Central Valley fall/late fall-run Chinook salmon juvenile outmigration may begin as early as November and extends through June.
- Central Valley spring-run Chinook salmon juvenile outmigration generally occurs from April through June.
- Central Valley steelhead juvenile outmigration generally occurs from December through March in the San Joaquin River, and continues through June in the Delta.
- North American green sturgeon outmigration of older juveniles generally occurs from June through September.

The presence of the protected floodplain likely would benefit juvenile fall/late fall-run Chinook salmon and steelhead during high-water events. The configuration of the floodplain being protected during high-water events would facilitate protection of juvenile salmonids as they are directed into the floodplain through backflow currents and are not displaced any further downstream.

Sommer et al. (2001) provided evidence that the Yolo Bypass, the primary floodplain of the lower Sacramento River, provides better rearing and migration habitat for juvenile Chinook salmon than adjacent river channels. During 1998 and 1999, salmon increased in size substantially faster in the seasonally inundated agricultural floodplain than in the river, suggesting better growth rates. Similarly, coded-wire-tagged juveniles released in the floodplain were substantially larger at recapture and had higher apparent growth rates than those concurrently released in the river. Improved growth rates in the floodplain were in part because of substantially higher prey consumption, reflecting greater availability of drift invertebrates. Bioenergetic modeling suggested that feeding success was greater in the floodplain than in the river, despite increased metabolic costs of rearing in the substantially warmer floodplain. Growth, survival, feeding success, and prey availability were higher in 1998 than in 1999, a year in which flow was more moderate, indicating that hydrology affects the quality of floodplain rearing habitat. These findings support the predictions of the flood pulse concept and provide new insight into the importance of the floodplain for salmon.

Work by Jeffries et al. (2008) and Sommer et al. (2001) indicate that off-channel floodplain habitats provide substantially improved rearing habitat, supporting higher growth rates than the intertidal river channel. However, their work shows that providing habitat complexity for juvenile salmon in floodplains is of utmost importance, so fish can find optimal places for rearing under varying flow conditions. It is well documented that survivorship to adulthood is increased when young salmonids leave freshwater at a larger size (Unwin 1997; Galat and Zweimuller 2001). Studies by Jeffries et al. (2008), Sommer et al. (2001), and others show that floodplain habitat restoration in Central California has major benefits to Chinook salmon populations, especially relative to growth and production. These studies indicate bioenergetic improvement to salmonids rearing in a flooded terrestrial floodplain because of the abundance of zooplankton (primary production), rather than having to rely on less dense prey items in the riverine channels, such as larval fish and benthic macroinvertebrates, and expending more energy for their capture. Therefore, construction of element IVc would be likely to result in bioenergetic improvement for all listed species.

EFFECTS RELATED TO THE 2017 EMERGENCY RESPONSE CONSTRUCTION PROJECT ACTIONS

Avoidance and minimization measures were implemented during the 2017 Emergency Response Construction Project. A worker environmental awareness program was provided to construction personnel prior to construction activities at element IVa, due to the proximity to potentially suitable riparian brush rabbit habitat. Construction personnel were notified of their responsibilities and provided with information on the life history of Federally listed species with the potential to occur in the construction footprint and vicinity. A biological monitor was onsite during all construction within element IVa. The biological monitor conducted preconstruction surveys for riparian brush rabbit, and was present to observe all construction activities within this area. See **Appendix H** for the construction monitoring report.

The implementation of the 2017 Emergency Response Construction Project did not result in adverse effects to valley elderberry longhorn beetle, because no elderberry shrubs were located within 100 feet of project activities. The implementation of the 2017 Emergency Response Construction Project did not result in adverse effects to special-status fish, because no waterside habitat was affected.

The implementation of the 2017 Emergency Response Construction Project resulted in the removal of 1.61 acres of potentially suitable habitat for riparian brush rabbit at element IIIb, IVa, Va, VIa.1, and VIbcde (see **Table 6**; see also **Appendix G**). No riparian brush rabbit was observed during the construction activities in this element, including during the removal of the vegetation. As described above under "Riparian Brush Rabbit" within this section, proposed conservation measures (see the "Avoidance and Minimization Measures" section above) would minimize direct loss of riparian habitat in conjunction with compensation for adverse effects. The Phase 3 Repair Project would include restoration of at least 9.9 acres of riparian scrub habitat and upland refugia in the setback area at element IVc (**Exhibit 12**). Implementing such measures is anticipated to avoid a net reduction in the number of riparian brush rabbit and its associated habitat.

CUMULATIVE EFFECTS

Cumulative effects include the effects of present, pending, and future State, tribal, local, or private actions that are reasonably certain to occur in the action area under consideration. The effects of projects that require a federal action are not considered in the cumulative effects evaluation during Section 7 consultation evaluation because they are subject to separate consultation (USFWS and NMFS 1998). For example, the Central Lathrop Specific Plan (Phase 1) addresses the development of 1,521 acres of land immediately east of the RD 17 levee elements IIIa and IIIb, south of Dos Reis and north of the housing development adjacent to element IVa. The USFWS issued a Biological Opinion for this project (USFWS File No. 1-1-06-F-0114), which analyzed the effects of the project on riparian brush rabbit and VELB. Therefore, this development is not considered cumulative to the proposed project. Also, the nonfederal action must be located in the action area, or project site, that is evaluated in the Section 7 consultation process (USFWS and NMFS 1998). Several present, pending, and future projects that are located in or near the action area under consideration in this consultation could result in effects similar to those of the proposed action.

SUMMARY OF PRESENT, PENDING, AND FUTURE PROJECTS IN THE PHASE 3 REPAIR PROJECT AREA

FLOOD DAMAGE REDUCTION SYSTEM IMPROVEMENTS

Two other proposed projects related to improvements to flood damage reduction systems are located near RD 17: the Lower San Joaquin River Feasibility Study, which would determine needed improvements for future flood protection systems in an effort to reach or exceed the future 200-year level of flood protection; and the Smith Canal Closure Structure, which would install a flood control gate in the Delta in Stockton, north of the Deep Water Ship Channel, to prevent flood flows from entering the Smith Canal in the event of an imminent or existing levee breach and during 100-year flood events.

These projects may affect federally listed species and require a federal action, and therefore would be subject to Section 7 consultation. Where adverse effects would occur on the landside of the levees, the project proponents may need incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Repair Project because they would undergo federal review and permitting as necessary—either through a Section 7 consultation or through SJMSCP compliance. This would ensure that adverse effects would be fully mitigated.

DEVELOPMENT PROJECTS

Development projects within the RD 17 boundaries include projects in the cities of Manteca, Stockton, and Lathrop, and in unincorporated areas of San Joaquin County. These projects have been described and analyzed in their respective environmental documents, including the following:

- River Islands Project;
- San Joaquin County General Plan 2010, adopted in 1992 and as amended;
- City of Stockton General Plan, adopted in 1990 and as amended through November 3, 1998;
- City of Lathrop General Plan, adopted in 1991 and as amended through January 2003;
- Central Lathrop Specific Plan, adopted in November 2004;

- West Lathrop Specific Plan, adopted in 1995;
- Manteca General Plan, adopted in 1988 and as amended through December 20, 1993;
- City of Lathrop Water, Wastewater, and Recycled Water Master Plan, adopted in 2001 and as amended through November 9, 2004;
- City of Manteca Wastewater Treatment Plant expansion; and
- 2001 Regional Transportation Plan, San Joaquin Council of Governments, 2001.

San Joaquin County covers approximately 909,000 acres, with approximately 809,000 acres (or nearly 90 percent of the county) used or available for agriculture (i.e., row and field crops, orchards, vineyards, and grazing lands). The remaining lands are dominated by various types of development (approximately 59,000 acres), natural habitats (e.g., woodlands, riparian), and open water (e.g., lakes, rivers, Delta waterways). Most county residents and development are located in incorporated cities (i.e., Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton, and Tracy). The SJMSCP anticipated that 147,000 acres of various categories of open space lands (including agriculture, range lands, and natural) in the county would be converted to non–open space uses between 2001 and 2051, based on full buildout of each of the general plans in the county and construction of all anticipated utility, transportation, and other public projects. In addition, approximately 59,000 acres of infill of urban lands were presumed to occur in this 50-year time frame.

Many development projects near the Phase 3 Repair Project area, including those described above, have been implemented recently or are in various stages of planning and entitlement, including the River Islands project. These current, pending, and potential future projects may affect federally listed species and require a federal action, and therefore would be subject to Section 7 consultation. Or, for those occurring within the SJMSCP permit area within San Joaquin County, the project applicants are expected to seek incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Repair Project because they would undergo federal review and permitting as necessary—either through Section 7 consultation or SJMSCP compliance.

ANALYSIS OF CUMULATIVE EFFECTS

GROWTH INDUCEMENT

Direct growth inducement would result if a project would include construction of new housing. Indirect growth inducement would occur, for instance, if implementing a project were to result in any of the following:

- substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises);
- substantial short-term employment opportunities (e.g., construction employment) that indirectly would stimulate the need for additional housing and services to support the new temporary employment demand; and/or
- removal of an obstacle to additional growth and development, such as removing a constraint on a required public utility or service (e.g., construction of a major sewer line with excess capacity through an undeveloped area).

Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density, or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Local land use decisions are within the jurisdiction of the cities and county in the Phase 3 Repair Project area: the City of Stockton, the City of Lathrop, the City of Manteca, and San Joaquin County. Each of these entities has adopted a General Plan consistent with State law. These General Plans provide an overall framework for growth and development within the jurisdiction of each agency, including the Phase 3 Repair Project area. Within the RD 17 boundaries, as elsewhere, population growth and urban development also are influenced by national, regional, and local economic conditions.

Because the Phase 3 Repair Project would not include construction of housing, it would not directly induce growth. Construction activities would generate short-term employment, but project-related construction jobs are expected to be filled from the existing local employment pool and not to indirectly induce growth or result in a population increase, nor would implementation of the project indirectly induce growth by creating permanent new jobs.

The Phase 3 Repair Project would accommodate growth currently approved or planned for undeveloped lands within the RD 17boundaries. These lands have been identified as the places most suitable for urban growth in the General Plans and additional planning policy documents of the cities of Lathrop, Manteca, and Stockton, and San Joaquin County. The Phase 3 Repair Project would allow development to proceed when economic and market conditions are favorable.

Development within the RD 17 boundaries is directed by the Central Lathrop Specific Plan and the West Lathrop Specific Plan in the City of Lathrop, the City of Stockton General Plan, the City of Manteca General Plan, and the San Joaquin County General Plan. The cities of Lathrop and Manteca are where the majority of planned or proposed development projects would be located. Environmental documents have been prepared to address the General Plans in these areas.

This information provides substantial evidence that the Phase 3 Repair Project would accommodate anticipated growth in a manner that would be consistent with adopted local growth management plans and with the State Plan of Flood Control. Thus, the Phase 3 Repair Project, despite accommodating buildout of adopted Specific Plans and General Plans in the cities of Lathrop, Manteca, and Stockton, would not be growth inducing itself.

CUMULATIVE EFFECTS ON LISTED SPECIES

Implementing the plans and projects described above would permanently disturb undeveloped land that currently is or has recently been in agricultural use. These projects would have cumulative effects on agricultural resources (by converting agricultural land to nonagricultural uses) and remnant native habitats (such as woodlands and marshes), which would have the potential to cause permanent adverse cumulative effects on the species, including federally listed species, for which these lands provide habitat.

Large areas of native riparian and wetland vegetation in the Phase 3 Repair Project area and Central Valley region have been lost or degraded over the past 150 years. USFWS estimates that more than 90 percent of wetland and riparian habitat has been lost in the Central Valley, compared to historic levels (USFWS 1989). Most losses have occurred because of CVP and SWP facility construction and alteration of flow patterns below dams, particularly channelization, and then clearing or filling behind levees for the conversion to agriculture and urban land uses. Alterations to the San Joaquin River channel have resulted over time in homogenous, trapezoidal channels with little instream structure; narrow and sparse bands of riparian vegetation that provide only limited SRA habitat functions; limited recruitment of large woody debris; and limited habitat conditions for native fish species and other aquatic organisms. This habitat conversion has affected many plant and wildlife species substantially, resulting in various species being listed as threatened or endangered under the ESA as well as under the California Endangered Species Act.

Present and future conversions of open space lands in San Joaquin County and the region consist primarily of converting agricultural lands to residential and urban development. Several flood risk management projects are

being implemented across the Central Valley, including San Joaquin County, to improve the integrity of levees. However, some of these flood risk management projects would implement compensatory mitigation in the form of habitat creation and preserves, designed to actually increase these habitats and their values related to ecosystem functions and special-status species. Upstream from the Phase 3 Repair Project area, the SJRRP would result in future structural and channel improvements to benefit special-status fish and wildlife species (Reclamation and DWR 2011). Nevertheless, even with these benefits, the overall losses of sensitive habitats in the Phase 3 Repair Project region, the numerous threatened and endangered species that are present, the ongoing declines of other species, and the continuing conversions of habitats and open space lands to various developments are evidence that past, present, and reasonably foreseeable future projects would combine to result in significant cumulative effects on biological resources.

Development projects (i.e., residential, commercial, industrial), infrastructure projects, and flood facilities improvement projects include or would include grading and other earthmoving activities that could result in temporary and short-term localized soil erosion that could affect hydrology and would have the potential to release materials (e.g., runoff of soils or contaminants) into the San Joaquin River. Potential increases in sedimentation, turbidity, and contaminants could expose and adversely affect fish and aquatic habitats. However, these site-specific effects are not expected to combine with the effects of other activities, because compliance with the NPDES regulations, including construction site BMPs, would help control erosion at each construction site. The effects from development projects, infrastructure projects, and flood facilities improvement projects would be temporary and short-term, and soil erosion would be localized.

CONCLUSIONS AND DETERMINATION

In conclusion, based on the biology and ecology of the federally listed species that have the potential to occur in the Phase 3 Repair Project area, the environmental baseline for the action area, and the effects of the proposed action and its cumulative effects, implementing the Phase 3 Repair Project may affect and is likely to adversely affect VELB and riparian brush rabbit, and would result in no adverse effect on delta smelt, Central Valley fall/late fall–run Chinook salmon, Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, and green sturgeon. Designated critical habitat in the action area has been designated for delta smelt, Central Valley steelhead, and green sturgeon; however, none would be adversely modified or destroyed.

- **Valley elderberry longhorn beetle:** The Phase 3 Repair Project may affect and is likely to adversely affect VELB by transplanting eight elderberry shrubs. Although VELB habitat credits comparable to 367 elderberry seedlings and 367 associated native plantings would be purchased from a USFWS-approved VELB habitat conservation bank to compensate for effects on VELB and effects on 268 elderberry stems (greater than 1 inch in diameter at ground level), an adverse effect on the species could occur. Removal of shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected, and a temporary loss of habitat available to the beetle during the establishment of seedlings would occur.

- **Riparian brush rabbit:** The Phase 3 Repair Project, including the 2017 Emergency Response Construction Project, may affect and is likely to adversely affect riparian brush rabbit by removing 3.28 acres of landside riparian habitat that is suitable for the species, contributing to the further reduction of available habitat for this species.

  However, the Phase 3 Repair Project would include restoring approximately 9.9 acres of compensatory riparian habitat (**Exhibit 12**) to offset project-related habitat losses. After the new setback levee in element IVc is constructed and certified, a small section of the existing levee then would be partially degraded. Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 9.9 acres that could be restored as riparian habitat (**Exhibit 12**). The restored riparian habitat would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where this species is documented to occur along the RD 17 levees. Apart from a small notch along the north side, the existing levee would remain in place, thus providing upland refugia for the species during high-water events. The restored habitat in the setback levee area would be contiguous with existing waterside riparian habitat along element IVc; this waterside riparian habitat along element IVc extends northward through elements IVa, IIIa, and IIIb, and southward through elements Va and VIa.1. Documented occurrences exist of riparian brush rabbit in the waterside riparian habitat in elements IIIa and IIIb, north of element IIIa and south of element VIa.1; therefore, reestablishing and protecting riparian habitat in element IVc would provide expanded and connected habitat for this species.

  RD 17 also is evaluating options for providing off-site compensatory habitat to offset Phase 3 Repair Project effects on riparian brush rabbit. Additional off-site compensatory habitats would include preserving existing waterside riparian habitats and/or restoring natural riparian habitats. These options would be evaluated in coordination with USFWS during the Section 7 consultation.

- **Federally listed fish species:** The Phase 3 Repair Project would result in no adverse effects on federally proposed and federally listed fish species considered in this BA. Effects are not expected to occur because of the avoidance and minimization measures to be implemented by the Phase 3 Repair Project. The Phase 3 Repair Project would include several measures that would avoid potential direct environmental effects during project construction. The potential effects of increased sedimentation or turbidity, and/or release of contaminants on fish and other aquatic organisms, would be avoided and minimized through the use of BMPs (e.g., source control, detention basins, revegetation, and spill containment plan) that would maintain surface water quality conditions in receiving waters and minimize disturbance to fish and other aquatic habitats. No waterside riparian or SRA habitat would be removed.

ESSENTIAL FISH HABITAT ASSESSMENT

The Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801), requires that EFH be identified and described in federal fishery management plans. Federal agencies must consult with NMFS on any activity that they fund, permit, or carry out that may adversely affect EFH. The EFH regulations require that federal agencies obligated to consult on EFH also provide NMFS with a written assessment of the effects of any action on EFH (50 CFR 600.920). NMFS is required to provide EFH conservation and enhancement recommendations to federal agencies. The statute also requires federal agencies receiving NMFS EFH conservation recommendations to provide a detailed written response to NMFS within 30 days of receipt, detailing how they intend to avoid, mitigate, or offset the impact of activity on EFH (Section 305[b][4][B]).

EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. For the purposes of interpreting the definition of EFH, "waters" includes aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include areas historically used by fish where appropriate; "substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities; "necessary" means habitat required to support a sustainable fishery and a healthy ecosystem; and "spawning, breeding, feeding, or growth to maturity" covers all habitat types used by a species throughout its life cycle.

The Pacific Fishery Management Council has identified and described EFH, adverse impacts, and recommended conservation measures for salmon in Amendment 14 to the Pacific Coast Salmon Fishery Management Plan (PFMC 2003). Amendment 18 to the Pacific Coast Salmon Fishery Management Plan revises the description and identification of EFH for Pacific salmon, designates habitat areas of particular concern, modifies the current information on fishing activities and potential measures to minimize their effects on EFH, and updates the list of fishing and non-fishing related activities that may adversely affect EFH and potential conservation and enhancement measures to minimize those effects (NMFS 2014c). Freshwater EFH for Pacific salmon in the Central Valley (i.e., Chinook salmon) includes waters currently or historically accessible to salmon within the Central Valley ecosystem, as described in Myers et al. (1998), and includes the segment of the San Joaquin River in the action area. EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia from high flows during floods as salmon migrate along the mainstem in this area. Although evidence of current or historical Chinook salmon distribution is lacking for the western tributaries (Yoshiyama et al. 2001), the lower reaches of these tributaries could provide juvenile rearing habitat or refugia. Central Valley fall/late fall–run Chinook salmon is a species managed under the Pacific Coast Salmon Plan that occurs in the San Joaquin River.

THE PROPOSED ACTION

The proposed action is described in detail in the "Description of the Proposed Action" section of this BA. The action area, environmental baseline, and species accounts, respectively, are described in the "Action Area," "Environmental Baseline," and "Species Accounts" sections of this BA.

ESSENTIAL FISH HABITAT DESIGNATION IN THE ACTION AREA

EFH has been identified for Chinook salmon, which includes Central Valley fall- and late fall-run Chinook salmon. EFH includes migration, holding, and rearing habitat and opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014a). EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia during floods as salmon migrate along the mainstem in this area (NMFS 2014c).

EFFECTS OF THE PROPOSED ACTION

Effects of the proposed action are described below and in the "Direct and Indirect Effects on Species in the Action Area" and "Cumulative Effects" sections of this BA.

Available literature indicates that limited Chinook salmon spawning typically occurs well upstream from the Phase 3 Repair Project area. EFH in the San Joaquin River in the vicinity of the Phase 3 Repair Project area consists of adult and juvenile (smolt) Chinook salmon passage between upstream spawning grounds and the Pacific Ocean, and limited in-channel rearing habitat for juveniles (limited because it is situated in a reach of the San Joaquin River that is bound on both banks by levees, resulting in channel incision, and is disconnected from its currently non-functioning floodplain). The river extends onto its floodplain only during high-water events, and if fish are swept into the floodplain during high flow conditions, they likely would become stranded because of the absence of a secondary channel for returning flood flows to the river. The Phase 3 Repair Project would result in improvement of EFH as functioning floodplain-rearing habitat and improvement to existing EFH in the San Joaquin River channel, by reducing and reversing the effects of current channel incision in the immediate vicinity of element IVc. Furthermore, approximately 2.5 acres of SRA habitat would be created and/or enhanced through revegetation actions between the river and the waterside toe of the existing levee in element IVc (see **Appendix E**).

Levee degradation and floodplain grading activities in element IVc would restore connectivity to the historic floodplain and improve habitat conditions in the floodplain. Although both actions would be constructed in dry conditions (above HTL), a potential short-term indirect effect of construction may be a temporary increase in sediment in the San Joaquin River, especially during the first storm or flooding event after construction. The measures (erosion control and revegetation) described in the "Avoidance and Minimization Measures" section of this BA are designed to reduce or capture any mobilized sediment resulting from the year's first rain or flooding event. Therefore, any construction-related sediment load would be temporary and negligible, especially when compared to the existing sediment load of the San Joaquin River and the project would not result in adverse effects on EFH.

The project would increase the amount and improve the quality of EFH in the project area. The new setback levee with floodplain in element IVc would improve EFH by providing refuge habitat for juvenile salmonids during high-water events, as described in Amendment 18 (NMFS 2014c). The newly reconnected floodplain would provide habitat for juvenile Chinook salmon rearing. It would also alter the channel dynamics in the immediate vicinity such that the channel incision process is expected to be reversed, thereby improving juvenile and adult migratory passage habitat.

PROPOSED CONSERVATION MEASURES

Proposed conservation measures are presented in the "Description of the Proposed Action" and "Direct and Indirect Effects on Species in the Action Area " sections of this BA. The measures include avoidance and minimization measures.

CONCLUSIONS

The proposed action would not affect the spawning, rearing, or migratory EFH functions of Chinook salmon currently or previously managed under the Magnuson-Stevens Fishery Conservation and Management Act in the San Joaquin River.

Andrea Shephard, Ph.D. .... Project Manager

Kelly Fitzgerald-Holland .... Biologist

Thomas Keegan and Steve Pagliughi .... Fisheries Specialists

Beth Duffey .... Technical Editor

Lisa Clement .... GIS Specialist

Brian Perry .... Graphics

Charisse Case .... Publishing Specialist

APPENDIX A

Exhibits

Refer to **Appendix A of Attachment 9 of Appendix J of this FEIS: Exhibits, on page 1363 of this PDF.**

APPENDIX B

Species Lists

Refer to **Appendix B of Attachment 9 of Appendix J of this FEIS: Exhibits, on page 1385 of this PDF.**

APPENDIX C

Evaluation of Potential for Giant Garter Snake Occurrence in the Phase 3 Repair Project Area

Refer to **Appendix C of Attachment 9 of Appendix J of this FEIS: Exhibits, on page 1401 of this PDF.**

Appendix D

Project Correspondence

APPENDIX D-1

Letter to USFWS and NMFS Requesting Technical Assistance, May 14, 2010

Refer to **Attachment 1 of Appendix J of this FEIS:**
Letter from AECOM to USFWS and NMFS Requesting Technical Assistance. May 14, 2010. Includes two attachments (2009 preliminary wetland delineation and 2010 updated wetland delineation), on page 955 of this PDF.

APPENDIX D-2

Letter from NMFS to AECOM Responding to Technical Assistance Request,
June 11, 2010

Refer to **Attachment 2 of Appendix J of this FEIS: Letter Responding to Technical Assistance Request. June 11, 2010, on page 1067 of this PDF.**

APPENDIX D-3

Letter from NMFS to USACE Requesting Additional Information,
July 7, 2015

Refer to **Attachment 4 of Appendix J of this FEIS: Letter from NMFS to USACE, Requesting Additional Information. July 7, 2015, on page 1173 of this PDF.**

APPENDIX D-4

Response to NMFS's July 2015 Request for Additional Information

Refer to Attachment 7 of Appendix J of this FEIS:
Letter from NMFS, Responding to Request for Additional Information. October 7, 2016, on page 1259 of this PDF.

APPENDIX D-5

Letter from USFWS to USACE Requesting Additional Information,
October 2, 2015

Refer to Attachment 5 of Appendix J of this FEIS:
Letter from USFWS to USACE, Responding to Request for Additional Information. October 2, 2015, on page 1183 of this PDF.

APPENDIX D-6

Response to USFWS' October 2015 Request for Additional Information

Refer to **Attachment 8 of Appendix J of this FEIS:**
Letter to USFWS, Responding to Request for Additional Information. October 7, 2016, on page 1275 of this PDF.

APPENDIX E

Conceptual Mitigation and Monitoring Plan for Levee Setback Area
June 2016

Refer to **Attachment 6 of Appendix J of this FEIS: Conceptual Mitigation and Monitoring Plan for Levee Setback Area – June 2016, on page 1191 of this PDF.**

APPENDIX F

Hydraulic Analyses of Setback Levee Alternatives

APPENDIX F-1

January 2010 Hydraulic Analysis of Reach IVc and Reaches IIa and IIb Levee Setback Alternatives

***Refer to* Appendix D.1 of this FEIS:**
January 2010 Hydraulic Analysis of Reach IVc and Reaches IIa and IIb Levee Setback Alternatives, dated January 19, 2010, Revised April 14, 2010, on page 679 of this PDF.

APPENDIX F-2

February 2014 Hydraulic Analysis of Reach IVc Levee Setback for Preferred Alternative

Refer to **Appendix D.2 of this FEIS:**
February 2014 Hydraulic Analysis of Reach IVc Levee Setback for Preferred Alternative, on page 743 of this PDF.

APPENDIX F-3

“Setback Levee Alternative” Excerpted from March 2, 2009, Reclamation District 17 Early Implementation Project Funding Application for 100-Year Levee Seepage Area Project – 2009 Project Elements

Refer to **Appendix F-3 of Attachment 9 of Appendix J of this FEIS: “Setback Levee Alternative” Excerpted from March 2, 2009, Reclamation District 17 Early Implementation Project Funding Application for 100-Year Levee Seepage Area Project – 2009 Project Elements, on page 1453 of this PDF.**

Subject: Construction Monitoring Report for Reclamation District 17's 2017 Emergency Response Construction Project

Dear Mr. Mueller:

GEI Consultants, Inc. (GEI) has prepared this Construction Monitoring Report (Report) for Reclamation District (RD) 17's 2017 Emergency Response Project (Project). The Project is located in south-central San Joaquin County, California, along the east bank of the San Joaquin River. On April 6, 2017, the U.S. Army Corps of Engineers (USACE) authorized (SPK-2009-001466) the discharge of fill into waters of the United States at Elements Ib, Ie, and IVa, which are distinct reaches along the San Joaquin River east levee, under Regional General Permit No. 8 (Emergency Actions). As part of the USACE's authorization, the agency sought input from the U.S. Fish and Wildlife Service (USFWS). Because the USFWS expressed concern over the Federally listed riparian brush rabbit (*Sylvilagus bachmani riparius*), RD 17 agreed to conduct construction monitoring for biological resources at Element IVa where vegetation was removed and a seepage berm was installed. On October 20, 2014, the Regional Water Quality Control Board issued a Technically Conditioned Water Quality Certification (WDID #5B39CR00238) for the larger Phase 3 Levee Seepage Repair Project.

Construction Monitoring – Methodology and Results

Biological monitoring was conducted along Element IVa of the Project on April 11, 13, and 17–20, 2017. During construction, the site had an average high of 69.7 degrees Fahrenheit and low of 49.7 degrees Fahrenheit, as well as 0.2 inch of precipitation on April 13 and 0.3 inch on April 18 (Stockton Metropolitan Airport). GEI biologist, Brook Constantz, was present at the construction site for 9 hours per day. The focus of the monitoring effort was to survey for riparian brush rabbit in the seepage berm construction limits and vicinity, and document the presence of birds, including special-status species and raptors, observed in this area.

Element IVa was surveyed for riparian brush rabbit presence and all areas of potentially suitable habitat within the construction limits and vicinity were investigated prior to the start of ground-disturbing activities. All construction activities were observed by the monitoring biologist to verify that any riparian brush rabbits that could be near the

GEI Consultants, Inc.

916.631.4500 fax 916.634.4501

construction activities in Element IVa were not harmed, harassed, injured, or killed as a result of Project implementation (**Photographs 1-3**). No riparian brush rabbits were observed during the construction of levee improvements in Element IVa.

During construction monitoring, all bird species observed within 500 feet of construction activities and Swainson's hawk within 1,320 feet were documented and observed. **Table 1** provides a list of bird species observed each day. During the preconstruction survey in Element IVa, a nest occupied by a European starling was observed inside a branch of a valley oak tree that was located within 100 feet of the construction limits; the top portion of this branch fell from the tree after the preconstruction survey exposing the nest which remained in the tree, but was abandoned before the first day of monitoring. No other species, including those listed under the Migratory Bird Treaty Act, were observed nesting within the project area or within 500 feet of construction activities. Swainson's hawk were not observed nesting within the project area or within 1,320 feet of construction activities.

Table 1. Bird Species Observed

Species	11-Apr	13-Apr	17-Apr	18-Apr	19-Apr	20-Apr
Red-winged Blackbird (*Agelaius phoeniceus*)	x		x	x		
Western scrub jay (*Aphelocoma californica*)		x	x			
Mallard (*Anas platyrhynchos*)			x			
Great egret (*Ardea alba*)				x		
Canada goose (*Branta canadensis*)			x			
Red-shouldered hawk *(Buteo lineatus)*			x	x	x	x
Swainson's Hawk (*Buteo swainsoni)*		x	x	x		
Anna's hummingbird (*Calypte anna*)			x			x
Northern flicker (*Colaptes auratus*)	x					
Common raven (*Corvus corax*)			x			
Brewer's black bird (*Euphagus cyanocephalus*)	x			x	x	x
House finch (*Haemorhous mexicanus*)						x
Black-necked stilt (*Himantopus mexicanus*)			x			
Dark-eyed junco (*Junco hyemalis*)	x	x	x			

Double-crested Cormorant (*Phalacrocorax auritus*)	x	x	x	x	x	x
White-faced Ibis (*Plegadis chihi*)		x	x	x	x	x
Black Phoebe (*Sayornis nigricans*)			x			
European starling (*Sturnus vulgaris*)			x	x		x
Tree swallow (*Tachycineta bicolor*)			x	x	x	
House wren (*Troglodytes aedon*)						x
Mourning dove (*Zenaida macroura*)					x	x

Photograph 1. Removal of water pipe crossing the levee before construction of the seepage berm.

Photograph 2. Spreading topsoil over fabric, the fabric is intended to prevent mixing between the soil and gravel layers.

Photograph 3. Spreading sand at the base of the seepage berm within the project area to prevent erosion.

Worker Environmental Awareness Program

A Worker Environmental Awareness Program was provided to construction personnel prior to construction activities at Element IVa. Specifically, construction personnel were notified of their responsibilities and provided with information on the life history of the special-status species with potential to occur within the construction footprint and vicinity. Avoidance and minimization measures were discussed and construction personnel were directed to contact the on-site biologist immediately if special-status species were encountered within the construction area.

If you have any questions regarding this Report please don’t hesitate to contact me at (916) 341-9125.

Best Regards,

Kelly Fitzgerald-Holland

12. Letter from USFWS to USACE, providing comments on Conceptual MMP. February 27, 2018.

Holland, Kelly

From: Schoenberg, Steven <steven_schoenberg@fws.gov>
Sent: Tuesday, February 27, 2018 8:33 AM
To: Lee, Kevin C CIV (US)
Cc: J. Stuart - NOAA Federal; Toland, Tanis J CIV CESPK CESPD (US); Shephard, Andrea; Holland, Kelly
Subject: FWS staff review of RD17 Phase 3 Project Conceptual MMP

Kevin/Tanis:

This responds to your request for review of the Conceptual Mitigation Monitoring Plan for RD 17 Phase III.

Background:

2010 - FWS receives technical assistance request from AECOM on behalf of RD17 due to potential effects on RBR (listed rabbit). Assistance from BDFWO and SFWO. Project is fix-in-place approach

2011 - FWS attends site visit; RD 17 revises to include setback in element IVc, considering Mainstone site for other/add'l effects not compensable on site.

Sept 2011 - DEIR, FWS and NOAA comment on general/specific concerns.

2013 - FWS previews/reviews draft COE comment responses (general opinion, many non-responsive to substance).

2014 - WQ certification (mentions VELB, not RBR); AECOM indicates potential seeking of SJMSCP coverage

2015 - COE initiates formal consultation 4/6/15; 30-day letters (insufficiencies) issued by NOAA 7/10/15 (includes additional ino on inundation elevation, frequency, duration, and ponding) and FWS 10/02/15 (includes, comment #3, additional information on management and monitoring - various specifics)

2016 - FEIR - says will retain current vegetation practice (not disturb lower 2/3 and 15' waterside; trim upper 1/3); will seek SWIF. Comment responses similar to those in 2013 preview; also includes conceptual mitigation/monitoring plan

2017 - 3/8/17 - COE reinitiates formal consultation/submits revised BA. Includes various appendices dealing with GGS potential, setback levee analysis, and a conceptual mitigation/monitoring plan (Appendix E)

3/22/17 - COE notifies FWS (SFWO) of emergency construction (letter not seen by BDFWO). SFWO recommends minimization/avoidance measures, and consultation at the conclusion of the project of any effects to listed species. Limited communication with me (BDFWO), of what was done; generally, this was believed to involve landside earth placement to stabilize areas where seepage was observed, and these locations overlapped to some extent the previously proposed work for RD 17 phase III.

1/12/18 - COE (Lee) requests review of the conceptual mitigation/monitoring plan.

Outstanding issues (of conceptual mitigation/monitoring plan, hereafter "CMMP") raised in 10/2/15 30-day letter:

"moderate level of specificity" of measures, responsible parties, funding assurance, protections, planting design, irrigation, measureable objectives, monitoring of such objectives, remedial measures, maintenance such as for non-natives, culling, firebreaks, inspection/patrol of human activities, and monitoring/effects on listed species; state if elderberries are included.

Comments on CMMP:

What is the total area of the site ? (Says it will have 10 acres riparian, p. E16; or is it 11 acres (E15) but expect other cover types also, correct? how much is upland - above moderate flood stage?)

E13-14: argument about value to RBR not being in grassland, however, these grasslands could be used occasionally for dispersal activity

E14: says will mitigate at a conservation bank, but later in plan (E15), says will plant elderberries here. Clarify.

E17: verify there is enough room/space/area to plant 367 elderberries and 367 associates.

General: the 1999 VELB "guidelines" document has been superseded by the FWS' May 2017 VELB "framework", document. Please review for consistency with what you propose.

E28: use of Oxbow Preserve; seems fair on first impression; though not sure about riparian/scrub density there compared to what is proposed here, or compared to ideal/objective for RBR.

E29-33: reasonable description of conceptual measures for starting the mitigation site.

E33: Says resource protection measures are the same as the repair project, but this is a mitigation site...which typically requires more oversight for aspects such as mentioned in the 10/2/15 letter (see also above).

E34-35: mentions that performance standards will be developed; monitoring to be continued until 2 years of independence achieved. No specifics yet. That may be OK for now...although, the site may require some level of perpetual oversight; also note VELB 2017 "framework" revises guidance.

E38: written confirmation of meeting mitigation obligations/responsibilities - seems fair as to establishment period - however - note that long term management/oversight remains a requirement.

E39: includes many of the management aspects as placeholders, as to be developed/submitted to FWS prior to construction; BiOP may require our approval in writing, of this LTMP, however. As placeholder, and at conceptual stage, this section of CMMP seems fair/appropriate.

As to the e-mail remark by Kevin (below) that these comments can be addressed in the later versions of the CMMP rather than in the BA, that too seems to be an acceptable approach.

Conclusion/Way Forward:

Based on my review, the CMMP as written is sufficient to proceed with re-initiation. However, at this time, FWS (at least BDFWO/me) has no information yet on the 2017 emergency work which was done and how it interfaces with the proposed work as described previously in the 2016 FEIR. Additionally, there are other issues raised in FWS' 10/2/15 30-day letter, which I (FWS) have not yet reviewed due and which may not be fully sufficient. Due to the circumstances of this project, namely - the length of time in planning, and the imminent risks as exposed by the need for emergency work, it is my opinion that the Corps should reinitiate consultation at its discretion, and that any further information needs (including insufficient responses to prior needs) identified be addressed wherever possible through prompt coordination between FWS and COE, at their respective staff levels. Hopefully, this will keep the consultation process moving toward a sooner, rather than later, completion.

Please note that these comments/conclusions/recommendations are at my staff-level only, and are subject to change pending internal discussion with FWS management.

If any questions, let me know.

Steve

On Fri, Jan 12, 2018 at 1:34 PM, Lee, Kevin C CIV (US) <Kevin.C.Lee@usace.army.mil> wrote:

Jeff and Steve,

As you know, the Corps suspended the transmittal of the updated BA to the Services due to the emergency levee work RD17 was conducting in response to the early 2017 high water event. We are preparing to send an updated biological assessment for the Phase 3 of the RD 17 Levee Seepage Repair Project that will include the 2017 Emergency Response Construction components.

This BA will include, as Appendix E, a Conceptual Mitigation Monitoring Plan for the proposed setback levee area, where up to 8 acres of floodplain would be restored and at least 9.9 acres of riparian brush rabbit habitat restored.

NMFS raised a number of questions and concerns about the design and function of the setback area. We feel that many of their questions/concerns would be addressed through their review of the Conceptual MMP. We request that NMFS and USFWS both review the Conceptual MMP, so that both agencies' comments on the setback area design and function are addressed jointly. We expect that most comments on the Conceptual MMP would be addressed through the Draft and Final versions of the MMP itself, rather than the BA.

Thanks,

Kevin

14. Letter to USFWS, responding to comments on Conceptual MMP. April 30, 2018.

April 30, 2018

RESPONSE TO U.S. FISH AND WILDLIFE SERVICE'S FEBRUARY 27, 2018, COMMENTS ON THE CONCEPTUAL MITIATION AND MONITORING PLAN FOR THE RD 17 PHASE 3 LEVEE SEEPAGE AREA PROJECT

This is in response to February 27, 2018, electronic mail from U.S. Fish and Wildlife Service (USFWS) to the U.S. Army Corps of Engineers, providing comments on the *Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project,* which is included at Appendix E to the proposed project's Biological Assessment. To respond to the USFWS comments, we have transcribed their comments and our responses into the matrix below.

#	Agency	Document / Page	Agency Comment	Response
1	USFWS	Conceptual Mitigation Monitoring Plan (CMMP) p. E15/E16	What is the total area of the site? (Says it will have 10 acres riparian, p. E16; or is it 11 acres (E15) but expect other cover types also, correct? how much is upland - above moderate flood stage?)	Total acreage is 11.2 acres; this includes 1.2 acres of contingency. Habitat types are: 5.0 acres Great Valley Oak Woodland; 6.1 acres of Great Valley Riparian Scrub; 0.2-acre roadway at the top of the levee prism.
2	USFWS	CMMP p. E13-14	Argument about value to RBR not being in grassland, however, these grasslands could be used occasionally for dispersal activity	Comment noted. Modified sentence as follows: "Although riparian brush rabbit may use annual grassland as foraging or dispersal habitat…."
3	USFWS	CMMP p. E14	Says will mitigate at a conservation bank, but later in plan (E15), says will plant elderberries here. Clarify.	Elderberries will be planted within the Great Valley Oak Woodland.
4	USFWS	CMMP p. E17	Verify there is enough room/space/area to plant 367 elderberries and 367 associates.	Average density of plantings would be approximately 250-330 plants per acre. There is adequate area for these plantings.
5	USFWS	General	The 1999 VELB "guidelines" document has been superseded by the FWS' May 2017 VELB "framework", document. Please review for consistency with what you propose.	Final MMP will update the document to reflect the 2017 framework.

#	Agency	Document / Page	Agency Comment	Response
6	USFWS	CMMP p. E28	Use of Oxbow Preserve; seems fair on first impression; though not sure about riparian/scrub density there compared to what is proposed here, or compared to ideal/objective for RBR.	The Final MMP will clarify the density objectives. A more complete evaluation of Oxbow Preserve as a reference site will be provided.
7	USFWS	CMMP p. E29-33	Reasonable description of conceptual measures for starting the mitigation site.	Comment noted.
8	USFWS	CMMP p. E33	Says resource protection measures are the same as the repair project, but this is a mitigation site...which typically requires more oversight for aspects such as mentioned in the 10/2/15 letter (see also above).	The MMP will be followed up with the development of a long-term management plan, which will be prepared in coordination with USFWS. This plan will describe site oversight requirements, including routine inspections and site maintenance (which is expected to focus on site protection to prevent trespass and vandalism).
9	USFWS	CMMP p. E34-35	Mentions that performance standards will be developed; monitoring to be continued until 2 years of independence achieved. No specifics yet. That may be OK for now...although, the site may require some level of perpetual oversight; also note VELB 2017 "framework" revises guidance.	Comment noted. This will be addressed in the Final MMP.
10	USFWS	CMMP p. E38	Written confirmation of meeting mitigation obligations/responsibilities - seems fair as to establishment period - however - note that long term management/oversight remains a requirement.	See response to comment 9.

#	Agency	Document / Page	Agency Comment	Response
11	USFWS	CMMP p. E39	Includes many of the management aspects as placeholders, as to be developed/submitted to FWS prior to construction; BiOP may require our approval in writing, of this LTMP, however. As placeholder, and at conceptual stage, this section of CMMP seems fair/appropriate.	Comment noted.
12	USFWS	General	Based on my review, the CMMP as written is sufficient to proceed with re-initiation. However, at this time, FWS (at least BDFWO/me) has no information yet on the 2017 emergency work which was done and how it interfaces with the proposed work as described previously in the 2016 FEIR. Additionally, there are other issues raised in FWS' 10/2/15 30-day letter, which I (FWS) have not yet reviewed due and which may not be fully sufficient. Due to the circumstances of this project, namely - the length of time in planning, and the imminent risks as exposed by the need for emergency work, it is my opinion that the Corps should reinitiate consultation at its discretion, and that any further information needs (including insufficient responses to prior needs) identified be addressed wherever possible through prompt coordination between FWS and COE, at their respective staff levels. Hopefully, this will keep the consultation process moving toward a sooner, rather than later, completion.	Comment noted. The BA has been updated to address the 2017 emergency work. Other items outlined in the USFWS' 10/2/2015 letter have been addressed through the revised BA and/or CMMP.

15. Letter to NMFS, responding to comments on Conceptual MMP. April 30, 2018.

April 30, 2018

RESPONSE TO NATIONAL MARINE FISHERIES SERVICE'S MARCH 14, 2018, COMMENTS ON THE CONCEPTUAL MITIATION AND MONITORING PLAN FOR THE RD 17 PHASE 3 LEVEE SEEPAGE AREA PROJECT

This is in response to March 14, 2018, electronic mail from National Marine Fisheries Service (NMFS) to the U.S. Army Corps of Engineers, providing comments on the *Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project,* which is included at Appendix E to the proposed project's Biological Assessment. To respond to the NMFS comments, we have transcribed their comments and our responses into the matrix below.

#	Agency	Document / Page	Agency Comment	Response
1	NMFS	Conceptual Mitigation Monitoring Plan (CMMP) p. E15	The design for the levee setback area is obviously focused on the needs of Riparian Brush Rabbit (RBR) and Valley Elderberry Longhorn Beetle (VELB). Out of 11.3 acres in the setback area, only 0.4 acres would be considered as inundated on a regular basis by design (fish swale). This minimizes potential benefits to native fish species (including salmonids) that a larger area of functional floodplain would provide.	The levee setback area is focused on RBR and VELB habitat. The fish swale has been removed from design to eliminate long term O&M concerns associated with sedimentation, access routes and fish stranding. The designed floodplain elevations will still provide important benefits to native fish species during high flow events. Primary benefits to native fish species would include velocity refugia, predator avoidance, and food web interactions.
2	NMFS	CMMP p. E16	The inundation of the fish swale is designed to occur approximately every 3-4 years and the lower floodplain every 6 years. This is less than a naturally functioning stream channel and associated floodplain. A typical natural floodplain would have an inundation cycle of every 2-3 years (the periodicity of bank full flow levels of a natural stream) where the stream overtops its banks and inundates portions of the surrounding floodplain.	The fish swale has been removed from design. The remaining area has been designed to function as a secondary floodplain to support riparian growth and enhance habitat for RBR and VELB. Inundation of this area on a 2-3year periodicity renders it ineffective as RBR and/or VELB habitat.

#	Agency	Document / Page	Agency Comment	Response
3	NMFS	CMMP p. E16	Use of native vegetation should provide benefits to native fishes during flood events.	The Final MMP will include description of this benefit.
4	NMFS	CMMP p. E17	The CMMP may need to develop a long term maintenance plan to ensure that stranding pools don't develop on the floodplain or within the swale, and that the swale drains correctly back to the river, or that future sedimentation does not raise the elevation of the floodplain to the point where it no longer meets the design inundation frequency.	The swale has been removed from the design. The area will be evenly graded to ensure drainage. The area will be inspected during the vegetation monitoring period to ensure proper drainage following inundation events.
5	NMFS	CMMP p. E20	Is there any potential to set the bench invert elevation to a height that will allow inundation to occur every 2-3 years (~normal bank full elevation)? This would get to a more functional floodplain system that would benefit native fish species.	No, the invert elevation cannot be lowered. Agree that a 2- to 3-year inundation periodicity would provide maximum to native fishes. However, the project is designed to provide habitat for VELB and RBR in a secondary floodplain/riparian habitat.
6	NMFS	CMMP p. E21	For NMFS' purposes, the percentage of days between December 1 and May 31 (i.e. the "wet" season) would be more helpful than days per year. The wet season is when the downstream migration of San Joaquin River salmonids is expected to occur. It also is when native fish species would be expected to use inundated floodplains for spawning.	At the design elevations the project area will only inundate during the "wet" season. It is unlikely that inundation events will provide the duration necessary for spawning and subsequent incubation periods for native species. Inundation events may provide benefit to emigrating and rearing salmonids. Benefits associated with emigrating salmonids is not reliant upon duration however, it is noted that longer duration periods would provide further benefit.

#	Agency	Document / Page	Agency Comment	Response
7	NMFS	CMMP p. E28	Is the Oxbow Preserve at the same elevation as the proposed set back levee area and thus would have the same inundation frequency? How do the proposed vegetation palettes for the setback levee area and the existing vegetation communities at the Oxbow Preserve compare? In order to be used as a baseline comparison, the reference site and the "experimental site" should have very similar physical and environmental characteristics so that a legitimate comparison can be made between the two sites. If the environmental and physical characteristics are too divergent, than direct comparisons become complicated and you are not sure what is driving any differences in the observed/ desired outcome.	A more complete evaluation of Oxbow Preserve as a reference site will be provided in the Final MMP.
8	NMFS	CMMP p. E29	Are there going to be any additional designs to benefit fish other than the fish swale? As stated earlier, it appears that this project is very focused on benefitting RBR and VELB and not as a holistic project that could benefit multiple species that use floodplains.	The fish swale has been removed from design and no further designs are anticipated to benefit native fish species.
9	NMFS	CMMP p. E30	If additional design elements to benefit native fish species are incorporated, earth moving equipment could be used "in the dry" before the levee is breached to achieve floodplain elevations and contours that have more inundation frequency, yet also allowing for escape corridors to high water refugia areas.	No additional design elements to benefit native fish species are anticipated.

#	Agency	Document / Page	Agency Comment	Response
10	NMFS	CMMP p. E34	Maintenance and Management of the site makes no mention of how the floodplain will be maintained at the design elevation in light of potential sediment accumulation during flood events. Will the design elevations be maintained or will the fish swale and floodplain be allowed to silt in?	The swale has been removed from the design. The area will be evenly graded to ensure drainage. The area will be inspected during the vegetation monitoring/establishment period to ensure proper drainage following inundation events.
11	NMFS	CMMP p. E36	Will any performance standards be developed for the functional performance of the floodplain during inundation (i.e., frequency of inundation, water depth, duration of water on the floodplain/ rate of water recession from the floodplain for the germination of riparian vegetation such as cottonwoods, etc.)?	Yes, the Final MMP will include additional information in sections “Performance Standards, Monitoring, and Reporting” and “Long-term Management Plan”.
12	NMFS	CMMP p. E38-39	Long term management plans should include how sedimentation issue will be addressed. Will the plan maintain a design inundation frequency by maintaining design elevations of the levee breach, fish swale, and lower floodplain?	The swale has been removed from the design. The area will be evenly graded to ensure drainage. The area will be inspected during the vegetation monitoring/establishment period to ensure proper drainage following inundation events.

Jeff and Steve,

As you know, the Corps suspended the transmittal of the updated BA to the Services due to the emergency levee work RD17 was conducting in response to the early 2017 high water event. We are preparing to send an updated biological assessment for the Phase 3 of the RD 17 Levee Seepage Repair Project that will include the 2017 Emergency Response Construction components.

This BA will include, as Appendix E, a Conceptual Mitigation Monitoring Plan for the proposed setback levee area, where up to 8 acres of floodplain would be restored and at least 9.9 acres of riparian brush rabbit habitat restored.

NMFS raised a number of questions and concerns about the design and function of the setback area. We feel that many of their questions/concerns would be addressed through their review of the Conceptual MMP. We request that NMFS and USFWS both review the Conceptual MMP, so that both agencies' comments on the setback area design and function are addressed jointly. We expect that most comments on the Conceptual MMP would be addressed through the Draft and Final versions of the MMP itself, rather than the BA.

Thanks,
Kevin

Comments to the RD-17 Conceptual Mitigation and Monitoring Plan (CMMP) for the Levee Setback Area

From: Jeff Stuart, Staff Fishery Biologist, NMFS Central Valley Area Office,

Page-#:

E-15: The design for the levee setback area is obviously focused on the needs of Riparian Brush Rabbit (RBR) and Valley Elderberry Longhorn Beetle (VELB). Out of 11.3 acres in the setback area, only 0.4 acres would be considered as inundated on a regular basis by design (fish swale). This minimizes potential benefits to native fish species (including salmonids) that a larger area of functional floodplain would provide.

E-16: The inundation of the fish swale is designed to occur approximately every 3-4 years and the lower floodplain every 6 years. This is less than a naturally functioning stream channel and associated floodplain. A typical natural floodplain would have an inundation cycle of every 2-3 years (the periodicity of bank full flow levels of a natural stream) where the stream overtops its banks and inundates portions of the surrounding floodplain.

E-16: Use of native vegetation should provide benefits to native fishes during flood events.

E-17: The CMMP may need to develop a long term maintenance plan to ensure that stranding pools don't develop on the floodplain or within the swale, and that the swale drains correctly back to the river, or that future sedimentation does not raise the elevation of the floodplain to the point where it no longer meets the design inundation frequency.

E-20: Is there any potential to set the bench invert elevation to a height that will allow inundation to occur every 2-3 years (~normal bank full elevation)? This would get to a more functional floodplain system that would benefit native fish species.

E-21: For NMFS' purposes, the percentage of days between December 1 and May 31 (i.e. the "wet" season) would be more helpful than days per year. The wet season is when the downstream migration of San Joaquin River salmonids is expected to occur. It also is when native fish species would be expected to use inundated floodplains for spawning.

E-28: Is the Oxbow Preserve at the same elevation as the proposed set back levee area and thus would have the same inundation frequency? How do the proposed vegetation palettes for the setback levee area and the existing vegetation communities at the Oxbow Preserve compare? In order to be used as a baseline comparison, the reference site and the "experimental site" should have very similar physical and environmental characteristics so that a legitimate comparison can be made between the two sites. If the environmental and physical characteristics are too divergent, than direct comparisons become complicated and you are not sure what is driving any differences in the observed/ desired outcome.

E-29: Are there going to be any additional designs to benefit fish other than the fish swale? As stated earlier, it appears that this project is very focused on benefitting RBR and VELB and not as a holistic project that could benefit multiple species that use floodplains.

E-30: If additional design elements to benefit native fish species are incorporated, earth moving equipment could be used "in the dry" before the levee is breached to achieve floodplain elevations and contours that have more inundation frequency, yet also allowing for escape corridors to high water refugia areas.

E-34: Maintenance and Management of the site makes no mention of how the floodplain will be maintained at the design elevation in light of potential sediment accumulation during flood events. Will the design elevations be maintained or will the fish swale and floodplain be allowed to silt in?

E-36: Will any performance standards be developed for the functional performance of the floodplain during inundation (i.e., frequency of inundation, water depth, duration of water on the floodplain/ rate of water recession from the floodplain for the germination of riparian vegetation such as cottonwoods, etc.)?

E-38-39: Long term management plans should include how sedimentation issue will be addressed. Will the plan maintain a design inundation frequency by maintaining design elevations of the levee breach, fish swale, and lower floodplain?

INTRODUCTION

The purpose of this Biological Assessment (BA) is to review Phase 3 of the Reclamation District No. 17 (RD 17) Levee Seepage Repair Project (LSRP) (Phase 3 Repair Project), including the components of the 2017 Emergency Response Construction Project (collectively "the proposed action"), in sufficient detail to determine the extent to which the proposed action may affect any of the federally listed species described below under "Species Considered." (See "Project Background and History" below for a brief summary of Phase 1 and Phase 2.)

RD 17, which is located in south-central San Joaquin County, California (**Exhibit 1**; see **Appendix A** for all exhibits), is responsible for maintaining 19 miles of levees along Walthall Slough, the San Joaquin River, and French Camp Slough, as well as the dryland levee along the southern boundary of Manteca. For discussion purposes, the RD 17 levees have been divided into 11 distinct "reaches," identified by Roman numerals (i.e., I, II, III…, XI), and subdivided further into 28 "elements," identified by the reach number followed by a lowercase letter and, where needed to further distinguish elements, an Arabic numeral (e.g., Ia, IIa, IIb, …, Va, VIa.1, VIa.2, VIa.4, …, VIe, VIIa, VIIb, …, VIIg…,XIa) (**Exhibit 2**).

This BA does not address the dryland levee (Reaches VIII – XI) because it is not a USACE flood risk management project, and therefore is not subject to Section 408 authorization. The dryland levee is an overland earthen berm, north and east of the San Joaquin River. Under almost all conditions, water does not come in contact with the dryland levee. It only functions as a flood risk management feature if water from the San Joaquin River or Walthall Slough leaves the banks of these waterways and inundates lands north and east, toward Manteca. The dryland levee then acts as an elevated earthen feature that prevents these flood waters from moving farther north. Suitable habitat for federally listed species does not occur along the dryland levee.

This BA has been prepared in accordance with requirements set forth under Section 7 of the federal Endangered Species Act (ESA) (16 United States Code [USC] 1536[c]). It supports formal consultation with the U.S. Fish and Wildlife Service (USFWS) and informal consultation with the National Marine Fisheries Service (NMFS) on the effects of the Phase 3 Repair Project on federally listed species and designated critical habitat. This BA also supports consultation with NMFS for project effects on Pacific Coast Salmon (*Oncorhynchus* spp.) essential fish habitat (EFH), as required by the Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801). (See the "Essential Fish Habitat Assessment" section below.)

Section 7(a)(2) of the ESA directs federal agencies to ensure that their activities are not likely to jeopardize the continued existence of any listed species, or to result in the destruction or adverse modification of critical habitat. This section of the ESA also requires agencies with regulatory authority over listed species to issue biological opinions evaluating the direct and indirect effects of federal actions, and actions that are interrelated or interdependent with the federal action. The biological opinions must determine whether the actions being evaluated may appreciably reduce the listed species' likelihood of surviving or recovering in the wild by reducing their productivity, numbers, or distribution.

To implement the Phase 3 Repair Project, RD 17 is requesting permission from the U.S. Army Corps of Engineers (USACE) for:

- alteration of federal project levees, pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408, referred to in this BA as "Section 408"); and
- placement of fill in jurisdictional waters of the United States, pursuant to Section 404 of the Clean Water Act (33 USC 1344, referred to in this BA as "Section 404").

All Phase 3 Repair Project work occurring on the water side of the levee would be above the high tide line (HTL). Therefore, no additional authorizations under Section 10 of the Rivers and Harbors Act of 1899 are required.

On April 6, 2017, the USACE authorized (SPK-2009-001466) the discharge of fill into waters of the United States at elements Ib, Ie, and IVa, under Regional General Permit No. 8 (Emergency Actions). The 2017 Emergency Response Construction Project was implemented in elements Ia, Ib, Ie, IIIb, IVa, Va, VIa.1, VIcde, and VIIb in February 2017. The majority of the 2017 Emergency Response Construction Project actions were already planned under the Phase 3 Repair Project; however, one component (i.e., a seepage berm) within elements Va and VIa.1 was not part of the actions planned specifically within these elements.

These 2017 Emergency Response Construction Project and the Phase 3 Repair Project activities are described in more detail under "Description of the Proposed Action." This BA analyzes direct, indirect, interrelated/ interdependent, and cumulative effects of the proposed action on federally listed species.

SPECIES CONSIDERED

This document considers species that have been termed "threatened" or "endangered" under the jurisdiction of USFWS and NMFS. On February 27, 2014, biologists consulted the online database maintained by USFWS's Sacramento Office to conduct a query of the Lathrop (462D) and West Sacramento (462A) 7.5-minute quadrangles (USFWS 2014) (**Appendix B**). Another query of the USFWS database was conducted on April 18, 2016 (USFWS 2016) (**Appendix B**), and the information in this BA was updated, based on those results. Using the California Department of Fish and Wildlife's (CDFW's) California Natural Diversity Database (CNDDB) (CDFW 2014) and the California Native Plant Society's database of rare and endangered plant species (CNPS 2014), biologists also conducted a query of the topographic quadrangles in which the action area occurs (Lathrop and Stockton West) and the surrounding quadrangles; these database queries were conducted on February 27, 2014, and March 3, 2014, respectively (**Appendix B**). This query identified all listed species in the area surrounding the action area, which is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 Code of Federal Regulations [CFR] 402.02).

Based on these database queries and the biologists' familiarity with local flora and fauna, 21 plant and wildlife species that are federally listed as endangered or threatened, or are federally proposed for listing were considered as part of this BA (**Table 1**).

The following federally proposed and federally listed species are known to occur or have the potential to occur in the Phase 3 Repair Project area (USFWS 2014, 2016):

- valley elderberry longhorn beetle (VELB) (*Desmocerus californicus dimorphus*),
- riparian brush rabbit (*Sylvilagus bachmani riparius*),
- delta smelt (*Hypomesus transpacificus*),
- Central Valley steelhead distinct population segment (DPS) (*Oncorhynchus mykiss*),
- longfin smelt (*Spirinchus thaleichthys*),
- Sacramento River winter-run Chinook salmon evolutionarily significant unit (ESU) (*O. tshawytscha*),
- Central Valley spring-run Chinook salmon ESU (*O. tshawytscha*),
- Reintroduced Central Valley spring-run Chinook salmon 10 (j) nonessential experimental population (*O. tshawytscha*), and
- the Southern DPS of North American green sturgeon (*Acipenser medirostris*).

The other federally listed species shown in **Table 1** were eliminated from further consideration; they are not likely to occur in the Phase 3 Repair Project area because of a lack of suitable habitat, local range restrictions, regional extirpations, or lack of connectivity between areas of suitable or occupied habitat, or because the action area is located outside the extant range of the species (see "Action Area" section below). The USFWS and NMFS-regulated species with the potential to occur on-site are discussed in more detail in this BA.

Table 1
Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project

Species	Status	Habitat	Potential to Occur in the Lower San Joaquin River[1]
Plants			
Large-flowered fiddleneck *Amsinckia grandiflora*	Endangered[2] SJMSCP-covered[4]	Annual herb with bright orange, trumpet-shaped flowers that bloom in late spring. Historically found on north-facing slopes in the upper elevations of grasslands near the blue oak belt in Contra Costa, Alameda, and San Joaquin counties.	No potential to occur. No suitable habitat is present in the action area.[3]
Palmate-bracted bird's-beak *Cordylanthus palmatus*	Endangered[2]	Annual herb that blooms from late spring through summer. Grows on seasonally flooded, saline-alkali soils in lowland plains and basins at elevations of less than 500 feet. Known from scattered locations in Sacramento and San Joaquin valleys; however, unlikely to occur in San Joaquin County because of lack of alkali habitat.	No potential to occur. No suitable habitat is present in the action area.[3]
Invertebrates			
Conservancy fairy shrimp *Branchinecta conservatio*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	Threatened SJMSCP-covered[4]	Inhabits elderberry shrubs, primarily in riparian woodland and scrub habitat.	Could occur; elderberry shrubs present occasionally along the San Joaquin River on the waterside and landside of the Phase 3 Repair Project levee; however, no evidence of beetle exit holes was observed in these shrubs.
Vernal pool fairy shrimp *Branchinecta lynchii*	Threatened SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Vernal pool tadpole shrimp *Lepidurus packardi*	Endangered SJMSCP-covered[4]	Inhabits vernal pools and swales.	No potential to occur. No suitable habitat is present in the action area.[3]
Fish			
Central Valley steelhead *Oncorhynchus mykiss*	Threatened	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Designated critical habitat is in the action area.
Central Valley fall/ late fall–run Chinook salmon *Oncorhynchus tshawytscha*	Species of Concern[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Likely to occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Occurs seasonally in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. Essential fish habitat for this species is in the Phase 3 Repair Project area.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
Delta smelt *Hypomesus transpacificus*	Threatened[2] SJMSCP-covered[4, 5]	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears seasonally in inundated floodplains, tidal marsh, and the Delta.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin rivers, tributaries, and Delta. Although no spawning habitat is in the action area, delta smelt has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.
Longfin smelt *Spirinchus thaleichthys*	Candidate/ Proposed Threatened[2] SJMSCP-covered[4, 5]	Pelagic estuarine. Ranges from the Delta in California northward to the Cook Inlet in Alaska.	Could occur. Occurs in tidally influenced segments of the Sacramento and San Joaquin rivers, tributaries, and the Delta. Although no spawning habitat is in the action area, longfin smelt has potential to occur in the San Joaquin River in the action area.[3]
Sacramento River winter-run Chinook salmon *Oncorhynchus tshawytscha*	Endangered[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. No spawning habitat is in the action area. Unlikely to occur in the San Joaquin River in the action area[3]; however, occasional adult and/or juvenile strays may be present.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	Threatened[2]	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Could occur, but unlikely. Occurs in the Sacramento River, tributaries, and the Delta. Currently unlikely to occur in the San Joaquin River in the action area[3]; no spawning habitat is in the action area. However, occasional adult and/or juvenile strays may be present.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	10 (j) nonessential experimental population	Requires cold freshwater streams with suitable gravel for spawning; rears seasonally in inundated floodplains, rivers, tributaries, and the Delta.	Could occur. Reintroduction of spring-run Chinook salmon is currently under way as part of the SJRPP[6] with the population designated as a 10(j) nonessential experimental population (NEP) by NMFS. A "nonessential" designation for a 10(j) experimental population means that, on the basis of the best available information, the experimental population is not essential for the continued existence of the species, and regulatory restrictions are considerably reduced under a NEP designation. When an NEP is located outside a National Wildlife Refuge or National Park (as the action area is), the population is treated as proposed for listing; is not protected by the ESA; and take is not prohibited.
Green sturgeon *Acipenser medirostris*	Threatened SJMSCP-covered[4, 5]	Requires seasonally inundated floodplains, rivers, tributaries, and the Delta.[5]	Could occur. Occurs in the Sacramento and San Joaquin rivers, tributaries, and the Delta. Has potential to occur in the San Joaquin River in the action area.[3] Designated critical habitat is in the action area.

Table 1
Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project

Species	Status	Habitat	Potential to Occur in the Lower San Joaquin River[1]
Amphibians and Reptiles			
California red-legged frog *Rana draytonii (=R. aurora draytonii)*	Threatened SJMSCP-covered[4]	Prefers semi-permanent and permanent stream pools, ponds, and creeks with emergent riparian vegetation and typically without predatory fish. Requires adequate hibernacula, such as small-mammal burrows and moist leaf litter.	No potential to occur. Potential aquatic habitat in the Phase 3 Repair Project area is limited to one constructed pond, likely with predatory fish, but the action area is outside the species' extant range.
California tiger salamander *Ambystoma californiense*	Threatened[2] SJMSCP-covered[4]	In winter, breeds in vernal pools and stock ponds that are fish-free and inundated for a minimum of 12 weeks. In summer, aestivates in rodent borrows in grassland habitat.	Unlikely to occur. Potential aquatic habitat in the Phase 3 Repair Project area is limited to one constructed pond, likely with predatory fish; a small area of freshwater marsh in element Ib[7]; and agricultural ditches. Much of the action area consists of urban and agricultural land that is not suitable as potential upland habitat. A 1996 CNDDB record documents California tiger salamander adjacent to State Route 120 in roadside seasonal wetland; however, it is approximately 2 miles east of the San Joaquin River and geographically isolated.
Giant garter snake *Thamnophis gigas*	Threatened[2] SJMSCP-covered[4]	Streams, sloughs, ponds, and irrigation/drainage ditches; also requires upland refugia not subject to flooding during the snake's inactive season.	Unlikely to occur. Although potential habitat for this species is present in the Phase 3 Repair Project area, none of it is suitable. The only documented occurrences of giant garter snake are separated from the Phase 3 Repair Project area by extensive urbanized development (City of Stockton) and large rivers that do not provide suitable habitat and are a greater distance than the species is known to disperse. For additional information that summarizes the rationale that supports the "unlikely to occur" determination for this species in the Phase 3 Repair Project area, refer to **Appendix C** in this document.
Birds			
Least Bell's vireo *Vireo bellii pusillus*	Endangered[2]	Nests in riparian habitat adjacent to riverine and freshwater marsh.	Unlikely to occur. Although suitable habitat is present, the last recorded observation of this species in the action area was in 1878, with no extant occurrences.
Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	Threatened SJMSCP-covered[4]	Insect-feeder that forages in dense riparian oak forest canopy along major rivers. Species is considered extirpated from San Joaquin County.	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Repair Project area, the action area is outside the species' extant range.
Mammals			
San Joaquin kit fox *Vulpes macrotis mutica*	Endangered SJMSCP-covered[4]	Annual grassland or grassy open stages with scattered shrubby vegetation; needs loose-textured	No potential to occur. Although potential dispersal and foraging habitat is in the Phase 3 Repair Project area, the action area is outside the species' extant range.

Table 1 Fish and Wildlife Species, Federally Listed or Proposed for Listing, Considered in Evaluation of the Phase 3 Repair Project			
Species	**Status**	**Habitat**	**Potential to Occur in the Lower San Joaquin River[1]**
		sandy soils for burrowing, and suitable prey base.	
Riparian brush rabbit *Sylvilagus bachmani riparius*	Endangered[2] SJMSCP-covered[4, 5]	Inhabits riparian oak forest with dense understory of wild roses, grapes, and blackberries; small home ranges, seldom moving more than a few feet from cover, avoiding large openings in shrub cover and frequenting small clearings.	Known to occur. Occupied riparian habitat is present on the waterside of elements IIIa and IIIb, and suitable habitat is present immediately adjacent to the project area in several elements; the species also is known to occur on an oxbow between elements VIa.1 and VIa.4[7] and in waterside habitat between elements IIab and IIIa.
Riparian (=San Joaquin Valley) woodrat *Neotoma fuscipes riparia*	Endangered SJMSCP-covered[4]	Requires healthy riparian forests, where it nests in cavities in trees, snags, or logs, spaces in talus, or lodges built of downed woody materials. Known to exist in and immediately adjacent to Caswell Memorial State Park, along the Stanislaus River in San Joaquin County.	No potential to occur. The action area is outside the species' extant range.

Notes: CNDDB = California Natural Diversity Database; Delta = Sacramento–San Joaquin Delta; ESA = Endangered Species Act; NEP = 10(j) nonessential experimental population; NMFS = National Marine Fisheries Service; Phase 3 Repair Project = Phase 3 of the proposed Reclamation District No. 17 Levee Seepage Repair Project; SJMSCP = San Joaquin Multi-Species Habitat Conservation and Open Space Plan; SJRRP = San Joaquin River Restoration Program

1 **Potential for Occurrence Definitions:**

No potential to occur; Suitable habitat is not present in the Phase 3 Repair Project area and/or the Phase 3 Repair Project area is not within the historical or current range of the species.

Unlikely to occur: Potential habitat present, but species unlikely to be present in the Phase 3 Repair Project area because of current status of the species, a very restricted distribution, and/or essential habitat components are not present.

Could occur: Suitable habitat is available in the Phase 3 Repair Project area; however, few or no other indicators show that the species may be present.

Likely to occur: Habitat conditions, behavior of the species, known occurrences in the Phase 3 Repair Project area, or other factors indicate a relatively high likelihood that the species would occur in the Phase 3 Repair Project area.

Known to occur: The species, or evidence of its presence, was observed in the Phase 3 Repair Project area during reconnaissance-level surveys or was reported by others.

2 These species have a similar status listing under the California Endangered Species Act, except for delta smelt and western yellow-billed cuckoo, which are both State-listed as endangered, and longfin smelt and San Joaquin kit fox, which are both State-listed as threatened.

3 Action Area: The action area is defined here in accordance with ESA guidelines as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project. Areas downstream from the Phase 3 Repair Project area may also be indirectly affected by the flood risk management component of the project through improved water quality and flood risk management conditions.

4 SJMSCP-covered: These species are covered under the SJMSCP (San Joaquin County 2000).

5 SJMSCP-covered with limitations: The SJMSCP does not cover the conversion of occupied riparian brush rabbit habitat, limits the amount of delta smelt habitat, and does not authorize take of green sturgeon.

6 See "San Joaquin River" subsection under "Environmental Baseline" section below, for more information.

7 Elements: The RD 17 levees have been divided into seven distinct "reaches" identified by Roman numerals (i.e., I, II, III), and subdivided further into 19 "elements," identified by the reach number followed by a lowercase letter and, in some cases, an Arabic numeral (e.g., Ia, IIa, Va, VIa.1…); see **Exhibit 2**.

SPECIES HABITAT AND POTENTIAL FOR OCCURRENCE IN THE AREA

The following is a summary of relevant habitat conditions in the action area for species that could occur, are likely to occur, or are known to occur in the Phase 3 Repair Project area. Full species accounts for federally listed species addressed in this BA are presented in the "Species Accounts" section.

- **Valley elderberry longhorn beetle:** Elderberry shrubs provide habitat for VELB. Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Repair Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Repair Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

- **Riparian brush rabbit:** Trapping conducted in February 2003 and February 2004 detected occurrences of riparian brush rabbit near the Phase 3 Repair Project area in waterside riparian habitat adjacent to elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1 and VIa.4 (CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004). The waterside habitat along elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The trapping locations between elements IIab and IIIa are dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The trapping locations between elements VIa.1 and VIa.4 are on an oxbow with dense riparian vegetation. Similar riparian habitat is present adjacent to the waterside of elements IIab, IVc, and Va. North of element IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, or isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species.

- **Delta smelt:** Delta smelt are found from Suisun Bay upstream through the Sacramento–San Joaquin Delta (Delta). Delta smelt disperse widely into freshwater in late fall and winter as the spawning period approaches, and may move as far upstream as Mossdale on the San Joaquin River (Bennett 2005). Therefore, this species has the potential to occur in the Phase 3 Repair Project area.

- **Longfin smelt:** Longfin smelt occur in the Delta and tidally influenced segments of the Sacramento and San Joaquin rivers. The occurrence of longfin smelt in the San Joaquin River is rare, but it does occur on occasion when river salinity extends farther upstream, either because of Delta pumping or because of drought. Therefore, this species has the potential to occur in the Phase 3 Repair Project area.

- **Anadromous salmonids:** The action area (see "Action Area" section below) does not provide suitable spawning habitat for salmonids because it lacks the cold freshwater and gravel substrate characteristic of salmonid spawning areas in upper river basins. However, adult and juvenile Central Valley steelhead could occur in the action area during migrations along the San Joaquin River and its tributaries. (Adult and juvenile Central Valley fall-run Chinook salmon could also occur in the action area during migrations along the San Joaquin River and its tributaries; this species is discussed under the "Essential Fish Habitat Assessment" section in this document). Winter-run and spring-run Chinook salmon are known to occur only in the Sacramento River and its tributaries (Moyle 2002). Because the action area is along the San Joaquin River, several miles upstream from its confluence with the Sacramento River, adult migrants along the Sacramento River are not expected to move into the action area. Reintroduction of spring-run Chinook salmon is currently under way as part of the San Joaquin River Restoration Program (SJRRP) with the population designated as a 10(j) nonessential experimental population (NEP) by NMFS. A "nonessential" designation for a 10(j) experimental population means that, on the basis of the best available information, the experimental population is not essential for the continued existence of the species, and regulatory restrictions are considerably reduced under a NEP designation. When an NEP is located outside a National Wildlife Refuge or National Park (as the action area is), the population is treated as proposed for listing; is not protected by the

ESA; and take is not prohibited. The goals of the SJRRP are "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River…including naturally reproducing and self-sustaining populations of salmon and other fish" (NMFS 2013).

- **Green sturgeon:** Green sturgeon are known to occur in the San Joaquin River and Delta, and therefore, has the potential to occur in the lower San Joaquin River in the Phase 3 Repair Project area (Moyle 2002). Currently, green sturgeon spawning in the San Joaquin River is not documented.

CRITICAL HABITAT

"Critical habitat" is defined in Section 3(5)A of the ESA as the specific areas in the geographical area occupied by the species where physical or biological features are found that are essential to the conservation of the species and that may require special management considerations or protection. Specific areas outside the geographical area occupied by the species also may be included in critical-habitat designations, based on a determination that such areas are essential for conservation of the species.

The proposed action addressed in this BA would fall within designated critical habitat for delta smelt, which was designated on December 19, 1994 (59 Federal Register [FR] 65256). Critical habitat is designated to include most tidally influenced areas of the Delta.

The proposed action addressed in this BA would fall within designated critical habitat for the Central Valley steelhead DPS. Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin river basins, including the segment of the San Joaquin River in the action area (see "Action Area" section below).

The proposed action addressed in this BA would fall within designated critical habitat for the Southern DPS of North American green sturgeon. Critical habitat for green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

The action area is not within designated critical habitat for the remaining species listed in **Table 1,** for which such a designation has been made: large-flowered fiddleneck, Conservancy fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, VELB, Sacramento River winter-run Chinook salmon ESU, Central Valley spring-run Chinook salmon ESU, California red-legged frog, California tiger salamander, and least Bell's vireo. Critical habitat has not been designated for palmate-bracted bird's-beak, longfin smelt, Central Valley fall/late fall–run Chinook salmon ESU, giant garter snake, western yellow-billed cuckoo, San Joaquin kit fox, riparian brush rabbit, or riparian woodrat.

SAN JOAQUIN MULTI-SPECIES CONSERVATION PLAN

All of the above species, except the anadromous salmonid fish species, are covered on some level under the San Joaquin Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) (San Joaquin County 2000). The SJMSCP was developed to avoid, minimize, and mitigate impacts on plant and wildlife habitat projected to occur in San Joaquin County between 2001 and 2051, resulting from the anticipated conversion of open space land to non–open space uses. Ninety-seven species are covered by the SJMSCP. The plan is intended to provide comprehensive mitigation, in accordance with local, State, and federal regulations, for impacts of SJMSCP-permitted activities on these species. USFWS and CDFW participated in development of the SJMSCP, approved the mitigation, and agreed to issue incidental take permits for species and activities covered by the SJMSCP.

The geographic area covered in the SJMSCP extends up to the landside levee crown of the San Joaquin River levee and includes the Phase 3 Repair Project area. However, the SJMSCP does not cover federal flood risk management projects or activities that involve tidally jurisdictional wetlands or other waters of the United States, and thus the Phase 3 Repair Project would not be a covered activity under the SJMSCP. The SJMSCP outlines a mechanism by which a federal flood risk management project, such as the Phase 3 Repair Project, could obtain take coverage under the SJMSCP (see Section 8.2.3 of the SJMSCP). However, because the SJMSCP does not cover special-status fish, the conversion of riparian brush rabbit habitat, or impacts on other species on the waterside of the levee, RD 17 and USACE would not rely on the SJMSCP to assess and offset Phase 3 Repair Project effects on federally listed and State-listed species. Rather, through this BA and the associated Section 7 consultations with USFWS and NMFS, RD 17 and USACE would seek take authorization for Phase 3 Repair Project activities. Species listed under the California Endangered Species Act that also are covered species under the SJMSCP would be evaluated through coordination with CDFW.

CONSULTATION TO DATE

The list below summarizes correspondence, meetings, and discussions between regulatory agencies, RD 17, and consultants that relate to potential effects of the Phase 3 Repair Project on species addressed in this document. The most recent consultation is listed first.

4/24/2018 USFWS provided GEI Consultants with guidance on updating the BA, specifically with regards to updating the effects analysis and proposed conservation measures to be consistent with the Framework for Assessing Impacts to the Valley Elderberry Longhorn Beetle (VELB Framework; USFWS 2017).

3/14/2018 NMFS provided USACE with comments on the *Conceptual Mitigation and Monitoring Plan for Riparian Brush Rabbit [for the] Phase 3 – RD 17 Levee Seepage Repair Project* (Conceptual MMP) (RD 17 2016) (**Appendix D-9**). A letter response to comments was completed by GEI Consultants, on behalf of RD 17 (**Appendix D-10**).

2/27/2018 USFWS provided USACE with comments on the Conceptual MMP (**Appendix D-7**). A letter response to comments was completed by GEI Consultants, on behalf of RD 17 (**Appendix D-8**).

1/12/2018 USACE provided USFWS and NMFS with copies of the Conceptual MMP, and requested their review of the document.

12/11/2017 Meeting with representatives from USACE, NMFS, and GEI Consultants to discuss the BA and Section 7 consultation with NMFS.

4/6/2017 Authorization from USACE issued to RD 17 for discharge of fill into waters of the United States for the 2017 Emergency Response Construction Project (SPK-2009-001466) under Regional General Permit No. 8 (Emergency Actions).

3/22/2017 USACE notifies USFWS of emergency construction.

3/8/2017 USACE submits request to USFWS and NMFS to re-initiate Section 7 consultation. Request includes submittal of revised BA.

4/18/2016 Letter from USFWS to GEI Consultants regarding the Species List for Phase 3–RD 17 Levee Seepage Repair Project (**Appendix B**)

10/2/2015 Letter from USFWS to USACE requesting additional information on the RD 17 Phase 3 Repair Project BA (**Appendix D-5**). A letter response to comments was completed by GEI Consultants and AECOM, on behalf of RD 17 (**Appendix D-6**).

7/7/2015 Letter from NMFS to USACE requesting additional information on the RD 17 Phase 3 Repair Project BA (**Appendix D-3**). A letter response to comments was completed by GEI Consultants and AECOM, on behalf of RD 17 (**Appendix D-4**).

2/27/15 Letter from USACE to NMFS transmitting the BA and requesting informal consultation.

2/27/15 Letter from USACE to USFWS transmitting the BA and requesting to initiate formal Section 7 consultation.

2/27/14	Letter from USFWS to AECOM regarding the Species List for RD 17 100-Year Levee Seepage Area Project[1] (**Appendix B**)
3/1/11	Tour of proposed action area with representatives from AECOM, USACE, USFWS, NMFS, and CDFW.
1/24/11	Meeting with representatives of USFWS and AECOM to discuss project permitting coordination, potential effects of the project on federally listed species, and development of a conservation strategy.
12/9/10	Meeting with representatives of CDFW and AECOM to discuss project permitting coordination, the potential effects of the project on State-listed species, use of the SJMSCP, and development of a conservation strategy.
8/24/10	Meeting with representatives of USACE, USFWS, NMFS, and AECOM to discuss the potential effects of the project on listed species and development of a conservation strategy.
6/11/10	Letter from NMFS to AECOM, responding to May 14, 2010, letter requesting technical assistance (**Appendix D-2**).
5/14/10	Letter from AECOM, prepared on behalf of RD 17, to USFWS and NMFS requesting informal technical assistance in evaluating the potential effects on listed species that could result from implementing USACE vegetation management standards, and in developing a conservation strategy to adequately offset the potential loss of habitat. Copies of the wetland delineation report and maps were provided with the letter (**Appendix D-1**).

1 "RD 17 100-Year Levee Seepage Area Project" is a reference to the RD 17 Levee Seepage Repair Project. This former name was used in documents published before preparation of the Final Environmental Impact Statement for Phase 3 of the RD 17 Levee Seepage Repair Project.

DESCRIPTION OF THE PROPOSED ACTION

U.S. ARMY CORPS OF ENGINEERS ACTION

RD 17, in cooperation with the California Department of Water Resources (DWR) and the Central Valley Flood Protection Board (CVFPB), is the local project sponsor for the Phase 3 Repair Project. RD 17 has requested permission from the CVFPB and USACE to alter segments of the San Joaquin River Levee System, which is a federal project levee. The proposed action for USACE is to make a permit decision on the Phase 3 Repair Project under the authority of Clean Water Act Section 404 and a permission decision under Section 408 of Title 33 USC. Under Section 408, USACE may allow the permanent use or occupancy of a USACE flood risk management project with approval by the Secretary of the Army on recommendation of the Chief of Engineers, provided that such use or occupancy would not be injurious to the public interest. USACE has determined that a Section 408 decision would be required for repair of seepage deficiencies to federal project levees. The activities requiring Section 408 and/or 404 authorizations, described in more detail below, include proposed alterations/repairs to USACE flood risk management facilities and fill of jurisdictional waters during earth-moving activities for levee construction. Activities for the Phase 3 Repair Project would be processed through an encroachment permit with the CVFPB. USACE would conduct a technical engineering review as part of the evaluation of the CVFPB's request to modify the Federal flood risk management project, in accordance with USACE regulations under 33 CFR 408.

PROJECT LOCATION

RD 17 is located in south-central San Joaquin County, California, in the center of the California Central Valley, at the north end of the San Joaquin River Basin, and within the far southeast limit of the Delta (see **Exhibit 1**). The boundaries of RD 17 are marked by French Camp Slough on the north, approximately 3 miles southwest of the central business district of the city of Stockton; the San Joaquin River on the west; Walthall Slough on the south (just below State Route 120); and Airport Way/McKinley Avenue on the east, just outside the city of Manteca. RD 17 is responsible for maintaining the levees along the east bank of the San Joaquin River from just south of Mathews Road to Walthall Slough, the levees along the north bank of Walthall Slough, and the dryland levee out to approximately South Airport Way (see **Exhibit 2**).

The proposed action is located along specific reaches of the RD 17 levees, as depicted in **Exhibit 2**. The Phase 3 Repair Project's landside levee improvements would include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system.

PROJECT BACKGROUND AND PURPOSE

PROJECT BACKGROUND AND HISTORY

The RD 17 system for reducing the risk of flood damage, like other flood protection systems in the San Joaquin Valley, initially was designed to facilitate agricultural development on the extensive valley floodplains and to support river navigation. Levees set closely along the rivers were designed to contain flows generated by common floods, and bypasses were constructed to carry overflows generated by large floods. The close-set levees ensured that water velocities would help scour the river bottom and move sediment through the system, reducing dredging costs for sustaining navigation. Starting in about 1863, RD 17 undertook the maintenance and reconstruction of the levee system.

Some of the levees in the Delta are considered "federal project levees." These levees were constructed or reconstructed (e.g., existing or damaged farm levees were improved) by USACE and are intended to meet federal standards. Construction of the federal levee system that encompasses the current RD 17 levees along Walthall

Slough, the San Joaquin River, and French Camp Slough began in 1944 and was completed in 1963. The levee system has since been upgraded substantially to meet Federal Emergency Management Agency (FEMA) requirements for flood protection during a 100-year flood event (flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability) [AEP]). In 1990, after extensive analysis, the RD 17 levees were accredited by FEMA as meeting the 100-year requirements for urban development.

During a high-water event on the San Joaquin River in January 1997, seepage and boils occurred at several locations along the RD 17 levees. USACE, DWR, and RD 17 successfully contained the seepage and boils, and the levees did not break. After the 1997 event, USACE, the CVFPB, and RD 17 funded a project, the Reconstruction of the California Central Valley Levees San Joaquin Basin #4, Reclamation District #17 Project, to repair the seepage and boil areas. The project was designed and constructed by USACE, and work was completed in 2003.

After reviewing the data supporting the 1990 accreditation and subsequent information, FEMA notified RD 17 of its intention to confirm full accreditation of the RD 17 levees as meeting FEMA's requirements for 100-year flood protection. On June 19, 2007, DWR wrote a letter to the City of Lathrop, with a copy to FEMA, stating that it could not support recertification of the RD 17 levees or the granting of provisional accreditation because of concerns about seepage exit gradients.[2] The basis of DWR's concern was analysis showing seepage exit gradients greater than 0.5, which indicated a higher likelihood of seepage or boils occurring during a high-water event Because of DWR's concern, FEMA then denied full accreditation and instead granted provisional accredited levee (PAL) status to the RD 17 levees. A PAL is a levee that FEMA has previously credited with providing a 100-year flood event level of flood risk reduction (i.e., flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability). In fall 2007, in response to the PAL status, RD 17 initiated a levee seepage repair program and requested funding through DWR's Early Implementation Program.

RD 17 subsequently implemented Phases 1 and 2 of the LSRP. After completion of the Phase 1 and 2 levee repairs, RD 17 submitted a recertification application to FEMA. In September 2010, RD 17 received a response letter declaring that FEMA had accredited the area protected by the RD 17 levee system, including the dryland levee, thereby removing the PAL status.

The Phase 1 Project included construction of two seepage berms, located in elements III and VI of the LSRP (**Exhibit 2**). The project reconstructed and extended the landside levee toe berms with earth and gravel fill, both landward and along the levee toe, to reduce seepage exit gradients. Work areas were designed to avoid any environmental resources of possible significance, including sensitive habitats and listed species. The project was determined to be categorically exempt from the California Environmental Quality Act (CEQA), and no federal authorizations or funding was required for the Phase 1 work; therefore, no National Environmental Policy Act (NEPA) analysis was triggered. The Phase 1 Project work was completed in January 2009.

The Phase 2 Project addressed work needed at nine levee reaches in the LSRP area. At eight of the nine reaches, the project involved constructing drained seepage berms along the landside levee toe. At one site that did not include seepage berm construction, RD 17 acquired an easement on land along the levee toe and performed various maintenance and site cleanup activities. A CEQA initial study/mitigated negative declaration that was completed for the Phase 2 Project concluded that no significant effects would occur on environmental resources after mitigation measures were implemented (RD 17 2009). Potential impacts on biological resources that resulted from Phase 2 Project implementation were mitigated through participation in the SJMSCP. No federal

[2] "Seepage exit gradient" is an expression in numeric form of the potential for under seepage to exit on the landside of a levee as seepage or a boil. The lower the number used to express seepage exit gradient, the more resistant the system is to seepage or boils; the higher the number, the more likely seepage or boils may occur during a high water event. In formulas for seepage exit gradients, the numerator (top number in a fraction) typically addresses forces that cause or enhance seepage (e.g., water pressure), and the denominator typically addresses forces that resist seepage (e.g., soil resistance to water pressure, depth and weight of soil over the potential seepage area, distance from the levee toe). A lower seepage exit gradient (i.e., more resistance to seepage) is achieved when the numerator (positive seepage forces) is reduced and/or the denominator (resistance to seepage) is increased.

authorizations or funding was required for the Phase 2 work; therefore, no NEPA analysis was triggered. All Phase 2 Project work was completed in summer 2010.

PROJECT PURPOSE AND OBJECTIVES

The overall purpose of the Phase 3 Repair Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.3 miles of the approximately 19-mile RD 17 levee system, to reduce the risk of flooding in the RD 17 service area during a 100-year flood event. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation. USACE and RD 17 each view the project purpose from the purview of their respective responsibilities, defined as follows:

USACE's objectives for the Phase 3 Repair Project are to:

- decide whether or not to grant permission for the RD 17 Phase 3 Repair Project to alter the federal project levees within its levee system under Section 408, and
- decide whether or not to issue permits under Section 404.

RD 17's objectives for the proposed Phase 3 Repair Project are to:

- repair seepage deficiencies where needed to meet current USACE seepage criteria standards,
- increase the levee's resistance to under seepage and/or through seepage,
- provide under seepage exit gradients equal to or less than 0.5 at the landside levee toe, and equal to or less than 0.8 at the landside drainage seepage berm at the water surface elevation associated with the design water surface, and
- meet levee geometry requirements of the permitting agencies in the specific areas of repair work.

All Phase 3 Repair Project work would occur on the landside of the existing levee system, or above the HTL on the water side of the levee, therefore, authorization under Section 10 of the Rivers and Harbors Act of 1899 would not be required. Section 404 authorization would be required for some work on the land side of the levee that would affect wetlands or waters of the U.S. USACE verified a wetland delineation that was submitted for the Phase 3 Repair Project on November 3, 2009 (a preliminary jurisdictional determination form was issued by USACE on November 10, 2009; USACE 2009b), and three supplemental wetland delineations were prepared. The first supplemental delineation was submitted on January 22, 2010 (a preliminary jurisdictional determination form was issued by USACE on April 9, 2010; USACE 2010a). The second supplemental wetland delineation was submitted on September 16, 2010 (a preliminary jurisdictional determination form was issued by USACE on October 7, 2010; USACE 2010b). The third supplemental wetland delineation was submitted on April 4, 2014 (a preliminary jurisdictional determination form was issued by USACE on April 7, 2014; USACE 2014a).

COMPLIANCE WITH USACE VEGETATION MANAGEMENT STANDARDS

With issuance of Engineering Technical Letter (ETL) 1110-2-571 in 2009,[3] USACE updated its vegetation management standards for levees, requiring the removal of all vegetation, with the exception of perennial grasses, on levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2009a). In September 2011, USACE issued a Draft Environmental Impact Statement/Draft Environmental Impact Report (DEIS/DEIR) for the Phase 3 Repair Project (USACE and RD 17 2011). The September 2011 DEIS/DEIR considered two options for complying with ETL 1110-2-571, as follows:

3 USACE ETL 1110-2-571 subsequently was replaced by ETL 1110-2-583 on April 30, 2014 (USACE 2014b).

- Full Implementation of USACE ETL 1110-2-571: All vegetation, other than perennial grasses, would be removed from the levee slopes and out 15 feet from the waterside and landside levee toes, or

- Acquisition of a Variance from Full Compliance with USACE ETL 1110-2-571: Permission would be obtained from USACE to retain all vegetation on the lower two-thirds of the waterside levee slope and out 15 feet from the waterside levee toe; all other levee vegetation still would be removed in accordance with USACE policy.

RD17 is no longer considering full compliance with the ETL as an alternative. RD 17 will continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which includes trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). In the Phase 3 Repair Project area, landside vegetation would be removed as previously evaluated in the September 2011 DEIS/DEIR (USACE and RD 17 2011) and as described under the "Additional Project Components" subsection below as well as in the "Direct and Indirect Effects on Species in the Action Area" section of this BA. Long-term vegetation management practices, for both landside and waterside vegetation, would be managed in accordance with the USACE O&M Manual which includes RD 17's existing practices, as described under the "Additional Project Components" subsection below as well as in the "Direct and Indirect Effects on Species in the Action Area" section of this BA.

DESCRIPTION OF THE PROPOSED PHASE 3 REPAIR PROJECT

This section describes the elements of RD 17's overall Phase 3 Repair Project; the Emergency Response Construction Project actions, which were authorized under Clean Water Act Section 404 Regional General Permit No. 8, are described under "Description of the 2017 Emergency Response Construction Project Actions" section that follows this section. This includes a description of the levee repair activities and additional project components that are proposed under the Phase 3 Repair Project, as well as the proposed construction schedule and sequencing.

The Phase 3 Repair Project would address the under seepage and/or through seepage concerns raised by DWR and repair and/or remediate levee geometry to USACE design standards along approximately 5.2 miles of the RD 17 levee system, including portions of the San Joaquin River east levee and portions of the levee along the northerly bank of Walthall Slough. Under seepage occurs below the aboveground levee prism and is caused by the buildup of water pressure in the subsurface foundation soils when high-river stages are present on the waterside of the levees. This pressure head causes water to flow through the earthen foundation layers under the levee and exit onto the ground surface on the landside of the levee prism (**Exhibit 3**). Such seepage is not uncommon and does not inherently imply that the levee is failing; however, excessive and uncontrolled under seepage can carry fine-grained material with the water flow that can undermine the levee and lead to levee failure. Through seepage is the movement of water through the levee prism when high-river stage conditions exist on the waterside of the levee (**Exhibit 3**). Depending on the duration of high water and the permeability of the levee embankment soil, seepage may exit onto the landside slope of the levee, thereby negatively affecting the stability of the landside levee slope.

Levee improvements along the USACE project levees would consist primarily of in-place repair/remediation, but would include a single setback levee at element IVc. As summarized in **Table 2** and shown in **Exhibits 4a** through **4c**, the Phase 3 Repair Project's landside levee improvements would include a combination of construction of seepage berms, installation of chimney drains and both shallow and deep cutoff walls, the raising of landside grade, and construction of a setback levee with seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system. These levee repair components, as well as additional project components (such as levee geometry corrections and stormwater management), are described in more detail following **Table 2**. The proposed action does not include any work that would raise the existing levee. Limited work would be performed along the waterside of the levee above the HTL in element IVc, where the setback levee would be constructed. As described in greater detail under the "Description of the 2017 Emergency Response Construction Project Actions" subsection, some seepage berms and raised landside grades in several elements were constructed during February 2017; **Table 2** summarizes, for each project element, the emergency construction actions that were implemented in 2017, as well as the remaining actions that would occur under the Phase 3 Repair Project.

LEVEE REPAIR ACTIVITIES

The Phase 3 Repair Project would include seepage berms, chimney drains, cutoff walls, a setback levee, and a raised landside grade (see **Table 2**). The respective levee improvement components are described below in more detail.

SEEPAGE BERMS

Reducing the risk of levee failure caused by under seepage and through seepage may be achieved by constructing a drained seepage berm. A drained seepage berm collects and conveys seepage, thereby reducing the flood risk associated with a high-water event. A drained seepage berm is built on the landside of a levee, and consists of layers of sand filter material, drain rock, geosynthetic filter fabric, and a seepage berm soil fill (**Exhibit 5**).

The drained seepage berm reduces flood risk during sustained high-river events by collecting seepage that otherwise would flow onto the landside ground surface at and beyond the levee's landside toe of slope, and then by conveying the seepage away from the levee. The layer of sand filter material placed on the natural ground surface serves to reduce the transmission of fine-grained soils into the drain rock, thereby maintaining the drain rock's ability to be a conductive soil unit that conveys collected seepage. Similarly, the filter fabric that separates the drain rock from the seepage berm fill soil prevents finer soils from migrating into the drain rock unit. The weight of the berm acts as ballast, reducing the potential for detrimental boils and piping.

The design width and height of a seepage berm are dependent on the relative permeability of the underlying soil layers and the amount of pressure head that push water under the levee and through these soils during sustained high-river events. The higher the water pressure head and the more dissimilar the porosity of the underlying soil layers, the wider and/or taller the seepage berm must be to prevent boils and reduce flood risk.

For the Phase 3 Repair Project, drained seepage berm widths of 60–120 feet are expected to be adequate to meet the design criteria in most cases (**Exhibit 5**). However, these types of berms may extend up to 300–400 feet inland from the landside toe of the levee. Seepage berms typically are constructed using select materials excavated from borrow sites or obtained from commercial sources. For the Phase 3 Repair Project, soil material for seepage berms would be purchased from commercial sources. A compacted-surface patrol road would be constructed near the outside edge of the seepage berm (see "Additional Project Components" below).

In urban areas, some seepage berms also would include a toe drain system (element VIIg) to safely collect and discharge the seepage water into an urban storm drainage system. A toe drain pipe is a below-grade, perforated pipe surrounded by a layer of sand and drain rock (**Exhibit 6**). The toe drain pipe is a mechanism to safely collect and convey seepage water away from the levee and seepage berm. If the toe drain pipe is unable to convey the seepage water, the water exits the drained seepage berm through the drain rock at the face of the berm, similar to a nonurban berm.

CHIMNEY DRAINS

A chimney drain is a drainage system that collects seepage waters that are flowing through the aboveground portion of the levee structure. This type of drain is used to collect and convey through seepage. A chimney drain consists of a 1 to 3-foot-thick layer of sand and drain rock. Filter fabric is placed between the soil and rock layer to avoid migration of the soil into the rock, which can clog the rock layer and reduce its ability to carry seepage flows. The chimney drain is placed directly on the landside slope of the levee and tied into an existing or new

Source: Data provided by Kjeldsen, Sinnock & Neudeck, Inc. in 2014, updated 2017 drained seepage berm at the landside base of the levee (**Exhibit 7**). The chimney drain conveys the through seepage flows to a drained seepage berm, which is located at the landside base of the levee.

Installing a chimney drain in an existing drained seepage berm would include adding the through seepage material on top of the existing seepage berm and tying this material into the existing seepage berm material by removing the seepage berm fill material and physically tying the two drainage rock layers together. When the remediation includes construction of a new drained seepage berm with a chimney drain, the chimney drain would be installed during construction of the drained seepage berm.

CUTOFF WALLS

In selected locations of the Phase 3 Repair Project, cutoff walls would be placed through the levee prism (parallel to the river). Cutoff walls use specialized earthen materials (often bentonite clay, which has low permeability, or a mixture of bentonite and cement). Cutoff walls would be constructed vertically through the levee prism, extending into or through deeper foundational soils that have low-permeability (a layer through which seepage does not flow readily). Thus, cutoff walls would substantially reduce the potential for under and through seepage flow during high-river events. Two methods for installing cutoff walls would be used along portions of the RD 17 levees: the conventional open-trench method and the deep soil mixing method.

The conventional open-trench method would be used to install shallow cutoff walls to a maximum depth of approximately 80 feet. This method involves excavating material in an open trench (the trench is filled with a bentonite slurry to maintain the side slopes of the excavation) and then replacing it with the select materials, typically a bentonite or cement-bentonite slurry (**Exhibit 8**). In this case, the top one-third to one-half of the levee height is "degraded," meaning that it is excavated so that any weakness in the narrow upper portion of the levee does not result in failure of the levee during construction.

For the deep slurry mixing method, specialized equipment (such as augers) is used to excavate deep into the subsurface, allowing the cutoff walls to reach depths up to 120 feet (**Exhibit 9**). The deep slurry mixing method involves mixing the soil in place with cement and / or bentonite, thereby reducing the risk of failure during construction. This method does not require levee crown degradation.

For the Phase 3 Repair Project, the cutoff walls would be extended approximately 300 feet beyond the element boundary to provide the required overlap when drained seepage berms have been or are being installed along the landside of adjacent levee elements. Levee slopes (where cutoff walls would be installed) also would be modified as needed to achieve the required 20-feet width and landside 3:1 slope.

SETBACK LEVEE WITH SEEPAGE BERM AND UNDERLYING CUTOFF WALL

General Description of Setback Levees

A setback levee is a levee constructed some distance behind an existing levee. The setback is tied into the existing levee at the upstream and downstream ends of the setback area. After certification of the setback levee, all or a portion of the existing levee between these two points typically is removed to allow high-water events to inundate the newly expanded floodway. Soil from the old levee may be used as a source of fill for other levee improvement projects, depending on the quality and quantity of material generated from demolition of the old levee. In some cases, it may be necessary to continue maintaining the existing levee after a setback levee is constructed (e.g., to protect existing development in the setback area) and to use the newly constructed levee as a backup levee.

General Description of Proposed Setback Levee and Associated Floodplain Restoration

Project Element IVc involves construction of a 1,100-foot-long setback levee with an underlying cutoff wall and a seepage berm, on a major oxbow of the San Joaquin River (see **Table 2**). A Conceptual MMP (RD 17 2016) was prepared to describe the expansion and restoration of riparian habitat in Element IVc (**Appendix E**), and submitted to USFWS and NMFS on January 12, 2018. This Conceptual MMP is being updated, in response to comments received from USFWS (on February 27, 2018) and NMFS (on March 14, 2018).

In the Phase 3 Repair Project area, soil materials beneath a setback levee are anticipated to have properties similar to those of materials below the existing levees. Therefore, a setback levee would have no seepage-related benefit in the RD 17 area relative to other seepage control methods; like the existing levees, a setback levee would require either a cutoff wall or drained seepage berm to sufficiently reduce the potential adverse effects associated with under seepage flows (**Exhibits 10** and **11**). Nevertheless, implementation of a setback levee could provide some additional capacity in the river for floodwaters and also would have the potential to provide habitat in the area between the new and old levee locations. In the Phase 3 Repair Project area, any newly expanded floodway created by a proposed setback levee would be designed to drain surface water after a high-water event, to prevent fish stranding.

Setback Levee Considerations

As described in greater detail under Section 2.1.4 in the DEIS/DEIR (USACE and RD 17 2011), and consistent with Section 2.5.1 of the forthcoming Final Environmental Impact Statement (FEIS) (USACE *in prep.)* for the proposed project, setback levees were considered but eliminated from further consideration in several project reaches for the following reasons:

- Construction of a setback levee along certain stretches of the river would be hydraulically constrained and would greatly increase the project scope to the point of being cost prohibitive (elements VIa.4 and VIb).
- Because of the proximity to the bifurcation at Old River, the change in hydraulic conditions that would result from constructing a setback levee at these locations would increase flows down the San Joaquin River during flood events, which could lead to increased flooding downstream (elements Va and VIa.1).
- Construction of a setback levee relative to other levee improvement alternatives and/or land acquisition to accommodate construction of a setback levee would be cost prohibitive (elements Ia, Ie, IIIb, IVa, VIcde, and VIIb).
- Existing landside development would constrain the option of constructing a setback levee (elements IIab, VIIe, and VIIg).

The complete hydraulic analyses that evaluated the setback levee alternatives are included as **Appendix F**.

Tie-in to Existing Levee

Where the new setback levee would intersect the existing levee, the top one-third to one-half of the crown of the existing levee would be degraded beginning with a 1:1 cut at the existing waterside crown to facilitate tying the cutoff wall and setback levee into the existing levee.

Riprap

Approximately 0.64 acres (740 linear feet) of riprap would be installed only on the waterside of the existing levee and above the HTL in element IVc where it would intersect the setback levee. No trees/shrubs would be removed to place the riprap and any riprap around trees/shrubs would be hand-placed. The riprap would not be installed to act as launchable rock.

Remnant Levee Breach

After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 8 acres of floodplain to the river.

Floodplain Offset Area

The reconnected floodplain area would be graded to allow complete drainage of the floodplain to the river. As flood flows recede, the floodplain area would drain completely through the breach in the remnant levee. This would minimize the possibility of fish stranding. The periodic reactivation of floodplain rearing habitat for juvenile salmonids, in particular, and other native fishes as well would be a benefit to fish resources. The seasonal nature of inundation, along with complete drainage, would preclude establishment in the floodplain of predatory, non-native fishes.

The Conceptual MMP evaluated three breach invert elevations (8 feet [NAVD88], 10 feet [NAVD88] and 14 feet [NAVD88]) for the proposed levee breach on the downstream end of the oxbow (RD 17 2016). Hydraulic modeling, based on San Joaquin River flows as reported at the Vernalis USGS stream gage (Vernalis gage), about 17.5 miles upstream of the project area, was used to estimate the flow in the San Joaquin River at which water would enter the setback area through the remnant levee breach for the three breach invert elevations. The results are shown in **Table 3**.

To evaluate how often and how long the levee setback area would be expected to inundate, a review was made of the historical Vernalis gage daily flow records since the completion of New Melones Dam in 1979 (this represents a period where the San Joaquin River basin operating regime has been relatively unchanged). The evaluation used the mean daily flows for the period October 1, 1978 through September 30, 2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. **Table 4** summarizes the estimated number and percent of days in the evaluation study period in which the levee setback area would flood based on the three invert elevations. Based on the historical data, the periods during which water would flow into the project breach at the three invert elevations are displayed in the figures below.

The appropriate breach elevation is under consideration and will be defined in the Final MMP. It is anticipated that the breach elevation would be set at approximately 9 or 10 feet (NAVD88). Approximately 1-2 acres of the floodplain would be set to an elevation of 14 feet (NAVD88) or below and would inundate approximately every 6 years.

Long-term Management of Floodplain Offset Area

The Final MMP will describe long-term and adaptive management strategies within the floodplain offset area. Long-term management actions for the riparian habitat area are expected to be minimal, and would be limited to regular site inspections to evaluate and address, as needed, site maintenance (e.g., trespass, vandalism, trash accumulation). In the event site conditions need to be addressed, maintenance activities would be conducted to avoid and minimize impacts to riparian vegetation and species habitat.

RAISED LANDSIDE GRADE

Directly adjacent to the landside toe of the levee in element Ib, an approximately 5-foot-deep depression was used as a borrow site to facilitate construction of the Howard Road Bridge. RD 17 would place fill within this depression to raise the landside grade.

Table 3 Estimated Flows for Inundation of the Element IVc Mitigation Site

ADDITIONAL PROJECT COMPONENTS

The following additional activities would occur as part of the Phase 3 Repair Project:

- **Levee geometry corrections:** Phase 3 Repair Project elements currently do not meet requirements for levee geometry (i.e., slopes, crown width). To correct levee geometry, levee fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot-wide levee crown. All elements would undergo some level of levee geometry corrections.

- **Operations and Maintenance (O&M) access and utility corridors:** A 20-foot-wide permanent O&M access corridor[4] would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.

- **Temporary construction easements:** Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the site(s) would be returned to pre-project conditions following completion of construction.

- **Stormwater /irrigation controls:** Drainage/irrigation swales would be constructed around the outside boundaries of levee repairs, where needed, and other stormwater best management practices (BMPs) would be implemented to manage stormwater runoff and/or irrigation during and after construction. These swales would be located so that they would not drain to/from wetlands or other waters of the U.S.

---

4 The CVFPB would require that a 20-foot-wide access corridor be established. However, on a case-by-case basis, effects on woody vegetation within this corridor may be avoided in place. However, for the purposes of the analysis in this FEIS, it was assumed that any vegetation within the 20-foot-wide corridor would be removed.

- **Right-of-way acquisition:** Lands within the Phase 3 Repair Project footprint would be acquired as needed, to accommodate levee repairs (e.g., seepage berms, setback levees) and establish the minimum 20-foot-wide O&M access corridor at the landside toes of all the improved levees, to prevent encroachment. Privately owned lands would be acquired in fee preferably, but may be taken as easements if needed. Where the project footprint overlies land owned and managed by other agencies (i.e., the City of Lathrop, San Joaquin County, Union Pacific Railroad [UPRR]), either the land would have to be acquired in fee or easements would have to be obtained and secured. Real property acquisition and any relocation services, if needed (although no relocations are anticipated), would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (42 USC 4601 et seq.) and implementing regulation, Title 49 of CFR Part 24, and California Government Code Section 7267 et seq.

- **Haul roads:** An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and cement) would be required to construct these levee improvements. These materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Phase 3 Repair Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would be public roadways, on and within 300 feet of the levees, existing unpaved roads used for access to work areas, and levee patrol roads atop the levee crown.

- **Landside vegetation removal:** Landside vegetation within the footprint of the proposed levee work, including maintenance roadway corridors and temporary access easements, would be cleared to prepare for levee repair work. The proposed action would involve performing limited work on the waterside of the levee above the HTL (e.g., installing riprap and degrading a portion of the levee in element IVc); however, no waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Encroachment management:** Several features, including power poles, vegetation, and a variety of agricultural-related facilities (e.g., irrigation infrastructure, fences), are within the Phase 3 Repair Project footprint. Utility infrastructure would be relocated as needed to accommodate the levee repairs, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Phase 3 Repair Project area would be removed or relocated as required to meet the criteria of USACE, the CVFPB, and FEMA. No waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Long-Term Vegetation Management:** Vegetation on the levees and within the access easements would be managed in accordance with current O&M practices to maintain access and visibility. These practices include: mechanical trimming of existing trees and removal of large dead and downed trees annually, as described under “Compliance with USACE Vegetation Management Standards”; regular summer and winter application of herbicides for weed control; and summer application of herbicides to control woody plants and berries.

Proposed Schedule and Sequence of Project Construction

Construction of the Phase 3 Repair Project is scheduled to begin in 2018, and is expected to be completed by December 2019, assuming receipt of all required environmental clearances, permits, and approvals for implementation. Some related activities, such as relocating power poles, may be conducted before levee work is begun, and site restoration and demobilization could extend through spring 2020. The general levee construction window is seasonal (July 1–November 1), avoiding the period when high-water levels have the potential to occur within the San Joaquin River system. However, depending on hydrologic conditions and subject to compliance with species work windows, a work window variance that allows an extension outside the July 1–November 1 work period may be granted by the CVFPB. The CVFPB may stipulate that RD 17 has to comply with additional conditions and commitments as a component of any work window variance.

The proposed construction sequence, which would include concurrent work in several different elements to meet the project schedule, is as follows:

- **Relocation of power poles:** Power poles currently situated on the landside of the levee toe of some elements would need to be relocated to accommodate proposed drained seepage berms. To the extent feasible, power poles would be relocated beyond the toe of the new berm, outside the maintenance access easement. If placing poles on top of the seepage berms is required, either raised foundations or steel-reinforced concrete piers would be constructed to prevent the poles from affecting the seepage berms. RD 17 would oversee relocation of the power poles, in coordination with the appropriate utility and construction companies.
- **Site preparation at existing levee sites and in levee setback area:** Site preparation (i.e., clearing, grubbing, and stripping) of the levee elements would begin by clearing structures (see discussion in next bullet) and woody vegetation from the footprint of the proposed levee work and the permanent O&M access and utility corridors. Vegetation would be retained in areas adjacent to but outside the project footprint. This operation would require removal of some trees and relocation or removal of some elderberry shrubs. Large trees would be felled approximately 3 feet above ground level, with stumps temporarily left in place. Where feasible, small trees and elderberry shrubs would be relocated. Elderberry shrubs would be relocated, in accordance with the avoidance and minimization measures outlined (see "Avoidance and Minimization Measures – Valley Elderberry Longhorn Beetle" subsection of this BA). A minimal amount of belowground disturbance would occur. The clearing operation would be followed by grubbing operations to remove stumps, root balls, and any below-ground infrastructure. The area then would be disked to chop surface vegetation and mix it with near-surface organic soils. The disking operation would be followed by stripping the top 12 inches of earthen material from the landside slope of the existing levee and the footprint of the proposed seepage berms. Excess earthen materials (i.e., organic soils, and excavated material that does not meet levee embankment criteria) would be temporarily stockpiled and then would be re-spread on the surface of the new levee slopes and seepage berms, provided this material is not contaminated with vegetation. Any stripped material contaminated with vegetation and other debris generated during the clearing and grubbing operations would be hauled off-site to a suitable landfill.
- **Removal or modification of landside structures and other facilities:** In a few levee elements, agricultural facilities (e.g., fences, drainage infrastructure) or parking lots are located within the footprint of the proposed levee work. These facilities would be removed from or relocated outside the project footprint before levee construction begins in those areas. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Demolished concrete could be sent to a concrete recycling facility. If any wells or septic systems would be affected, they would be abandoned in accordance with the applicable State and County requirements.
- **Construction of the setback levee with drained seepage berm and underlying cutoff wall:** Construction of the setback levee embankment in element IVc would begin as soon as sufficient lengths of levee foundation are prepared and weather conditions are suitable. Foundation preparation would include constructing a levee keyway that would be excavated 3–5 feet deep across the entire footprint of the proposed setback levee. A smaller but deeper excavated inspection trench, centered beneath the new waterside hinge point of the setback levee, then would be constructed beneath a small portion of the keyway to meet DWR standards. After the foundation layers are backfilled with engineered soil, a geotechnical geogrid fabric would be installed at ground level across the entire setback levee footprint. A second layer of geogrid fabric would be placed at mid-height of the new levee fill section to further reduce the potential for post-construction settlement of the new levee. The embankment would be constructed of engineered fill, with the fill placed in 3-foot-maximum lifts by motor graders. Each lift would be moisture-conditioned using water trucks and would be compacted to the specified density using a suitable compactor, such as a sheep's foot, tamping foot, or rubber-tired roller. Next, quarry stone riprap would be applied in three segments, to armor the newly completed setback levee's waterside slope and protect against erosion. Riprap would be placed on the waterside levee above the HTL in areas that are characterized by ruderal land cover (**Exhibit 12**). All waterside woodland would be avoided; all waterside trees would be avoided as well as any tree canopy that

overlaps riprap. Riprap placement would be done either by barge or by long-arm excavator from the top of the levee crown. Riprap dimensions for the three segments are: 340 feet long by 50 feet wide (0.39 acre), 140 feet long by 30 feet wide (0.096 acre), and 230 feet long by 50 feet wide (0.26 acre). A drained seepage berm then would be constructed on the landside of the setback levee. Fill material for setback levee and drained seepage berm construction would be obtained from commercial sources and would be delivered to levee construction sites using haul trucks.

- **Setback levee site restoration and demobilization:** After completion of construction, the previously stripped topsoil material would be placed on top of the completed setback levee and associated seepage berms in element IVc, and levee slopes and the tops of the seepage berms would be hydroseeded. An aggregate-base patrol road would be constructed at the landside edge of the seepage berm and setback levees and on the new setback levee crown. The existing levee would be fully restored at the tie-in points to the new setback levee. The existing levee crown patrol road would be redressed with aggregate base, to restore it to preconstruction levels. Any disturbed riprap also would be supplemented to provide a uniform layer across the connection point with the new setback levee. Immediately after final construction, the setback levee's fill slopes would be covered with erosion control material until application of the hydroseed. Any construction debris would be hauled to an appropriate off-site waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization would be likely to occur in various locations as construction proceeds along various elements.

- **Removal of existing levee at setback levee elements, site restoration, and demobilization:** After certification of the new setback levee and seepage berm in element IVc, a 400-linear-foot-long section of the existing outboard levee (which is approximately 2,400 linear feet long in element IVc) on the downstream side of the existing oxbow would be partially degraded. The area where the levee would be degraded is characterized by ruderal land cover (**Exhibit 13b**); some landside vegetation would be removed (as accounted in the "Direct and Indirect Effects on Species in the Action Area" section of this BA), but all waterside trees and overlapping tree canopy would be avoided. Except for an approximately 20-foot-wide corridor on the top of the remnant levee that will be serve as a maintenance road to provide access to the remnant levee breach area for maintenance and flood fighting purposes, at least 9.9 acres (and up to 11.1 acres) of riparian vegetation would be established in the area between the new setback levee and the river (**Exhibit 12**) (see the "Compensation Measures" subsection of the "Avoidance and Minimization Measures" section below for additional information). This acreage would be made up of approximately 6.1 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee and between the river and the waterside toe of the existing levee, and approximately 5 acres of restored Great Valley oak woodland/upland refugia habitat along either side of the existing levee. These acreages would include approximately 1.2 acres of contingency, with the goal of restoring a minimum of 9.9 acres of riparian habitat. This work would be completed after flood season (from July 1 through November 1) and above the HTL, primarily using scrapers, excavators, and bulldozers to remove the levee section and all present levee encroachments.

- **Construction of drained seepage berms, drained seepage berms with chimney drains, and chimney drains within existing drained seepage berms:** Fill material for levee improvements would be obtained from commercial sources and delivered to the levee construction sites by haul trucks. The material then would be spread by motor graders and compacted by sheep's foot rollers to build new seepage berms and seepage berms with chimney drains. A water truck would be used to properly moisture-condition the soils for compaction. Installing the chimney drains in existing drained seepage berms also would require use of an excavator or scraper to remove the existing drained seepage berm fill material so that the chimney drain fill material can be tied into the drainage rock layer of the existing drained seepage berm.

- **Construction of cutoff walls:** Equipment required for cutoff wall construction would include slurry batch plants to prepare bentonite or bentonite cement mix, pumps, and support vehicles. Four to five batch plants or slurry ponds would be required for the project; these would be located near the site of cutoff wall construction. Each batch plant or slurry pond with associated pumps and support equipment would occupy an area of approximately 100 square feet that would be restored to pre-project conditions following completion of cutoff wall construction. Cutoff walls may be installed concurrently in two or more different directions within an element. RD 17 proposes to use the deep slurry mix method for installing deep cutoff walls, which would avoid the need to degrade the top of the levee, and conventional slurry trench walls (open-cut method) for shallow cutoff walls. RD 17 also would consider driving sheet piles, using a drop impact hammer or other pile-driving technology in lieu of cutoff wall installation at element VIIe. The number of cutoff wall rig setups would depend on the project schedule and contractor preference. Each deep slurry mix cutoff wall rig would move continuously along the proposed alignment, to attain an uninterrupted cutoff wall and reduce prolonged disturbance to residences near some cutoff wall segments. Each cutoff wall rig could move 50 to 100 feet horizontally during a 12-hour work shift, while each conventional slurry trench rig could move 75 to 200 feet horizontally during a 12-hour work shift. Cutoff wall construction in Elements Va and VIa.1 is anticipated to occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance, when necessary. Lights and possibly power generators would be used during nighttime construction hours. Disturbances to nearby residences are expected to be minor because of the limited number of residences near these cutoff wall installation areas. However, where lights, noise, and/or vibration would exceed allowable nighttime standards for the applicable local jurisdiction, work hours would be restricted to daytime work hours.

- **Traffic control during construction:** Traffic control and detours could be required in the immediate vicinity of some levee improvements. Traffic control measures would include flaggers for one-way traffic control, advance construction signs and other public notices to alert drivers to activity in the area, and “positive guidance” detour signage on alternate access roads to reduce inconvenience to the driving public. Detours for through traffic are not likely to be required.
- **Site restoration and demobilization:** On completion of construction, previously stripped topsoil material not contaminated with vegetation would be placed on top of the completed seepage berms and any disturbed levee slopes. Any previously nonagricultural, vegetated areas disturbed during construction would be hydroseeded with a standard erosion control mix. An aggregate-base patrol road would be constructed at the landside edge of any seepage berms. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization likely would occur in various locations as construction proceeds along various elements.

DESCRIPTION OF THE 2017 EMERGENCY RESPONSE CONSTRUCTION PROJECT ACTIONS

The 2017 Emergency Response Construction Project that was implemented in February 2017 included the construction of seepage berms and raised landside grades in several elements (see **Appendix G** for as-builts). Most of these activities were already planned under the Phase 3 Repair Project. All the seepage berms and raised landside grades that were installed for the emergency response, even those where cutoff walls will be done in the future as proposed under the Phase 3 Repair Project, would remain in place. **Table 2** summarizes, for each project element, the emergency construction actions that were implemented in 2017, as well as the remaining actions that would occur under the Phase 3 Repair Project.

All of the emergency response construction project components were included within the Phase 3 Repair Project, except for the new seepage berm that was constructed in elements Va and VIa.1. This seepage berm was evaluated in the FEIS ((USACE *in prep.)* under Alternative 2 – Maximum Footprint, but not carried over into the Preferred Alternative, which is the Phase 3 Repair Project. However, this seepage berm overlaps with the footprint for the Phase 3 Repair Project (compare **Exhibit 13b**, in **Appendix A**, to Sheets 9 and 11 of **Appendix G**).

AVOIDANCE AND MINIMIZATION MEASURES

The following avoidance and minimization measures would be implemented as a component of the Phase 3 Repair Project. The measures, where applicable, were implemented during the 2017 Emergency Response Construction Project (see "Effects Related to the 2017 Emergency Response Construction Project Actions" subsection under the "Direct and Indirect Effects on Species in the Action Area" section of this document).

GENERAL

A qualified biologist, retained by RD 17, will be on-site to ensure compliance with the avoidance and minimization measures described below, particularly where construction activities occur adjacent to sensitive habitats to be avoided.

A worker awareness training program will be conducted for construction crews before the start of construction. The program will include a brief overview of special-status species and sensitive resources (including riparian habitats) in the Phase 3 Repair Project area, measures to avoid and minimize effects on those resources, and conditions of relevant regulatory permits.

Furthermore, traffic speeds on unpaved roads will be limited to 15 miles per hour, to reduce dust emissions and minimize potential effects on listed species, such as the riparian brush rabbit.

VALLEY ELDERBERRY LONGHORN BEETLE

For elderberry shrubs that are located in the Phase 3 Repair Project area, RD 17 will implement the following avoidance and minimization measures that are described in the VELB Framework (USFWS 2017) to avoid and minimize effects on VELB:

- All elderberry shrubs that are located adjacent to construction areas but can be avoided will be protected by establishing a fenced avoidance area. The fencing will be placed at least 20 feet from the dripline of the shrubs. All elderberry shrubs to be protected during construction will be identified and marked by a qualified biologist. Orange construction barrier fencing will be placed at the edge of the respective buffer areas, and no construction activities will be permitted within the buffer zone other than those activities necessary to erect the fencing. In cases where the elderberry dripline is less than 20 feet from the work area, k-rails will be placed at the shrub's dripline to provide additional protection to the shrubs from construction equipment and activities. Temporary fences around the elderberry shrubs and, where appropriate, k-rails at shrub drip lines will be installed as the first order of work. Buffer area fences around elderberry shrubs will be inspected weekly by a qualified biologist during ground-disturbing activities, until adjacent project construction is complete or the fences are removed on approval by a qualified biologist and the resident engineer.
- No insecticides, herbicides, or other chemicals that may harm the beetle or its host plant will be used within 100 feet of elderberry shrubs.
- Elderberry shrubs that require removal will be transplanted to a USFWS-approved site during the dormant period for elderberry shrubs (i.e., November 1 to February 15) and in accordance with the VELB Framework (USFWS 2017).
- Each elderberry shrub with stems measuring 1 inch or greater in diameter at ground level that may be adversely affected (i.e., transplanted), as well as any associated riparian habitat that would be removed, will be replaced with compensatory plantings and/or the purchase of credits at a USFWS-approved conservation bank, in accordance with the VELB Framework (USFWS 2017).

Regarding provision for off-site compensatory mitigation for habitat losses, see the "Compensation Measures" subsection below.

RIPARIAN BRUSH RABBIT

The following measures will be implemented to avoid and minimize potential adverse effects on riparian brush rabbit in potential habitat within and adjacent to the Phase 3 Repair Project footprint (i.e., Great Valley cottonwood and Great Valley oak riparian forest communities):

- Potential riparian brush rabbit habitat will be identified and avoided wherever possible. The primary engineering and construction contractors will ensure, through coordination with a qualified biologist who is pre-approved by USFWS and retained by RD 17, that construction will be implemented in a manner that minimizes disturbance of such areas to the extent feasible.

- Temporary fencing will be used during construction to prevent disturbance of potential habitat adjacent to construction areas. Construction personnel, vehicles, and equipment will remain within the identified construction area. In addition, a silt fence or other suitable temporary barrier will be installed around the construction area where it borders suitable habitat for brush rabbits, to exclude brush rabbits from the construction site; this silt fence or temporary barrier either will be incorporated into the temporary fencing or will be installed as a separate fence. Temporary signage will be placed along the rabbit exclusion fence at 150-foot intervals, warning contractors to stay within the construction area. The temporary rabbit exclusion fence and associated signage will be inspected by a qualified biologist and the construction contractor each morning before the beginning of construction activities, and will be repaired and maintained as necessary. A biological monitor will inspect the fence at least once a week. The temporary rabbit exclusion fence and signage will be removed after construction activities are no longer occurring adjacent to the exclusion area.

- Where suitable habitat for riparian brush rabbit has to be removed, vegetation will be removed by hand 2 weeks before the start of construction so that no riparian brush rabbits are present in the construction area at the time of construction. A qualified biologist, retained by RD 17, will be on-site during vegetation removal. Areas of temporary habitat disturbance in the Phase 3 Repair Project area will be revegetated with native plant species and restored to pre-project conditions.

Regarding provision for on-site compensatory mitigation for habitat losses, see the “Compensation Measures” subsection below.

FEDERALLY LISTED FISH—DELTA SMELT, LONGFIN SMELT, ANADROMOUS SALMONIDS, AND GREEN STURGEON

The following measures will be implemented to avoid and minimize potential adverse effects related to lights, noise, and vibration:

- During nighttime construction, RD 17 will use shielded lighting that is directed away from the waterside levees.

- Vibratory compaction equipment will be specifically restricted on the RD 17 levees. The limited amount of compaction that would occur on landside chimney drain locations would be restricted to normal work day hours.

The following measures will be implemented to avoid and minimize potential adverse effects on water quality:

- Any work within the existing floodway (i.e., placing riprap on the waterside levee above the HTL at element IVc) of the San Joaquin River will not take place during the designated flood season (i.e., November 1 to July 1) and will not begin until evaluation of upstream conditions (e.g., reservoir storage and snowpack) indicate that inundation of these areas will be unlikely to occur during construction.

- RD 17 will comply with all local, State, and federal regulations and environmental requirements regarding turbidity-reduction measures, including the following:

  - obtaining and complying with relevant agency permits (e.g., CDFW streambed alteration agreement, Central Valley Regional Water Quality Control Board [RWQCB] Clean Water Act Section 401 certification, and Section 404 permit);

  - developing and implementing a storm water pollution prevention plan (SWPPP) that identifies specific BMPs to avoid and minimize effects on water quality during construction activities; and

  - complying with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity.

- RD 17 will file a notice of intent with the Central Valley RWQCB to discharge stormwater associated with construction activity. Final design and construction specifications will require implementation of standard erosion, siltation, and good housekeeping BMPs. Construction contractors will be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for construction activity (Order No. 2009-0009-DWQ or the current permit in place at the time of construction). The SWPPP will describe the construction activities to be conducted, BMPs that will be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that will be conducted.

  At a minimum, the following specific BMPs will be implemented:

  - All work will be conducted according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized.

  - Silt fences and/or straw wattles will be installed near riparian areas or existing drainages to control erosion and trap sediment and reseed cleared areas with native vegetation.

  - Maintenance will be conducted on a regular basis to ensure proper installation and function of BMPs, and during storm events, maintenance will be conducted daily.

  - BMPs that have failed (within 48 hours of an event) will be repaired and replaced immediately with sufficient devices and materials (e.g., silt fence, coir rolls, and erosion blankets), provided throughout project construction to enable immediate corrective action for failed BMPs.

  - Stockpiling of construction materials (e.g., portable equipment, vehicles, and supplies, including chemicals) will be restricted to designated construction staging areas, exclusive of any riparian, wetland, or other areas supporting waters.

  - Disturbed soils at construction areas will be stabilized before the onset of rainfall.

  - Stockpiles will be stabilized and protected from exposure to rain and potential erosion.

  The SWPPP also will specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of effects from use or accidental spills or releases of contaminants. Specific measures applicable to the project will include the following:

  - Compliance will be required by RD 17 contractors with all applicable State Water Resources Control Board (SWRCB) and Central Valley RWQCB standards and other applicable water quality standards.

- Strict on-site handling rules will be developed and implemented, to keep potentially contaminating construction and maintenance materials out of drainages and other waterways.
- When refueling and servicing equipment, absorbent material or drip pans will be used underneath such equipment to contain spilled fuel, oil, and other fluids; and any fluid drained from machinery will be collected in leak-proof containers and deliver to an appropriate disposal or recycling facility.
- Controlled construction staging and fueling areas will be maintained at least 100 feet away from channels or wetlands, to minimize accidental spills and runoff of contaminants in stormwater.
- Substances that can be hazardous to aquatic life will be prevented from contaminating the soil or entering watercourses.
- Spill cleanup equipment will be maintained in proper working condition. All spills will be cleaned up immediately according to the spill prevention and response plan, which will be prepared by RD 17 or its contractor or representative and will be approved by the RWQCB before the start of project groundbreaking.
- NMFS, USFWS, CDFW, and the Central Valley RWQCB will be notified immediately (within 24 hours) of any reportable spills and cleanup occurrences. All such spills, and the success of the efforts to clean them, will be recorded in post-construction compliance reports.
- A slurry spill contingency plan will be developed, which will be prepared by RD 17 or its contractor or representative before the start of project groundbreaking, to respond to a potential for bentonite slurry spill and prevent slurry from entering watercourses.
- Construction materials handled by RD 17 or its contractors will be stored and transported in a manner that minimizes potential water quality effects. Storage areas will be located away from drainages and waterways, outside the floodplain, and away from sensitive resources, and containment facilities will be used.

BMPs will be applied to meet the "maximum extent practicable" and "best conventional technology/best available technology" requirements and address compliance with water quality standards. RD 17 will implement a monitoring program during and after construction so that the Phase 3 Repair Project complies with all applicable standards and BMPs implementation is effective.

COMPENSATION MEASURES

VALLEY ELDERBERRY LONGHORN BEETLE

As described above under "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle," compensation for effects on VELB will be provided in accordance with the VELB Framework (USFWS 2017). Elderberry shrubs that cannot be avoided will be transplanted to the levee setback area in element IVc (**Exhibit 12**). The restoration design, as outlined in the Conceptual MMP (**Appendix E**), will include elderberry seedlings and associated species plantings to compensate for the effects on VELB habitat in the Phase 3 Repair Project site. Transplanting unavoidable elderberry shrubs and planting elderberry seedlings and associated species (in an amount determined through compliance with the VELB Framework) will fully compensate for the loss of VELB habitat resulting from construction activities associated with the Phase 3 Repair Project.

Approximately a 3:1 restoration to impact mitigation ratio (for effects on riparian habitat associated with elderberry shrubs) will be accomplished in the restoration area, with approximately 9.9 acres (and up to 11.1 acres) of riparian forest and riparian scrub habitat restored. The expansion and restoration of riparian habitat in element IVc will augment the waterside riparian corridor along the San Joaquin River. This habitat creation and enhancement will fully compensate for the loss of riparian habitat associated with elderberry shrubs resulting from construction activities associated with the Phase 3 Repair Project.

Riparian Brush Rabbit

Compensation for effects on riparian brush rabbit habitat will consist of restoring natural habitats in the Phase 3 Repair Project area.

As described in more detail in the Conceptual MMP (**Appendix E)**, on-site compensation for adverse effects on riparian brush rabbit habitat will include restoration of at least 9.9 acres (and up to 11.1 acres – allowing for approximately 1.2 acres of contingency) of riparian habitat in the proposed levee setback area in element IVc. This acreage will be made up of approximately 6.1 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee and between the river and the waterside toe of the existing levee, and approximately 5 acres of restored Great Valley oak woodland/upland refugia habitat along either side of the existing levee. The total of amount of potential compensatory mitigation acreage would be at least 9.9 acres to achieve the compensation for riparian brush rabbit habitat.

After the new setback levee is constructed and certified in element IVc, a small 400-foot section of the existing levee will be partially degraded. Native riparian scrub vegetation will be established within the entire setback area floodplain. Species in the plant palette will be those preferred by the riparian brush rabbit for providing cover, including: California blackberry (*Rubus ursinus*), California wild rose (*Rosa californica*), sandbar willow (*Salix exigua*), coyote brush (*Baccharis pilularis*), and golden currant (*Ribes aureum*), among others. Understory vegetation will include herbaceous species that have been identified as preferred forage by the riparian brush rabbit, such as mugwort (*Artemisia douglasiana*) and gumplant (*Grindelia camporum*). To provide refugia during flood events, the old levee footprint also will be vegetated with riparian scrub and riparian woodland tree species. The upland refugia will include elderberry seedlings and associated species plantings to compensate the effects on VELB habitat in the Phase 3 Repair Project area. In addition to plantings within the setback area, waterside riparian vegetation will be enhanced with plantings in open areas.

Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4 acres of ruderal grassland that can be restored as riparian scrub habitat (**Exhibit 12**). Approximately 2 additional acres of riparian scrub habitat will be restored and/or enhanced between the waterside toe of the existing levee and the river. The restored riparian scrub habitat will consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee will remain in place and approximately 5 acres of Great Valley oak woodland will be established along either side of it, thus providing upland refugia for the riparian brush rabbit during high-water events.

Approximately a 3:1 restoration to impact mitigation ratio (for effects on potential riparian brush rabbit habitat) will be accomplished in the restoration area, with approximately 9.9 acres (and up to 11.1 acres) of riparian brush rabbit habitat restored. The expansion and restoration of riparian habitat in element IVc will augment the waterside riparian corridor along the San Joaquin River and will provide additional riparian habitat for the riparian brush rabbit between two known occurrences of this species (i.e., between elements IIIa/IIIb and elements VIa.1/VIa.4 [CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). The restoration area will be contiguous with existing waterside riparian habitat along element IVc; this waterside riparian habitat along element IVc extends northward through elements IVa, IIIa, and IIIb, and southward through elements Va and VIa.1. Documented occurrences exist of riparian brush rabbit in the waterside riparian habitat in elements IIIa and IIIb, and north of element IIIa and south of element VIa.1; therefore, reestablishing and protecting riparian habitat in element IVc will provide expanded and connected habitat for this species. This habitat creation and enhancement will fully compensate for the loss of habitat for riparian brush rabbit resulting from construction activities associated with the Phase 3 Repair Project.

MITIGATION AND MONITORING PLAN

A Conceptual MMP has been prepared to describe the expansion and restoration of riparian habitat in element IVc (**Appendix E**). Specifically, this plan:

- describes specifications for the restoration of habitat components, including details about the restoration of riparian habitats, with a list of the plant species and drawings/designs to show the location of the plant species and planting density;
- establishes specific success criteria for the habitat components, including:
  - performance standards to determine whether the habitat improvement was trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions);
  - monitoring and maintenance protocols; and
  - measurable goals to ensure vegetation survival to provide and replace riparian habitats;
- specifies remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring); and
- describes short and long-term management and maintenance of the habitat lands.

The Conceptual MMP is intended to be developed into a Final MMP, in coordination with USFWS, NMFS, and USACE, and would be reviewed and approved by USFWS and NMFS before ground-breaking in the portions of the Phase 3 Repair Project area that could affect the species addressed in this BA. RD 17 would provide conservation of the restored riparian habitat in the levee setback area in element IVc. The compensation habitat ultimately would be transferred to a suitable land management organization, for long-term management and monitoring. This habitat creation and enhancement would fully compensate for the loss of habitat for VELB and riparian brush rabbit resulting from construction activities associated with the Phase 3 Repair Project.

ACTION AREA

The action area is defined in accordance with ESA guidelines as “all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action” (50 CFR 402.02). The action area includes all areas that would be directly or indirectly affected by the components of the Phase 3 Repair Project and the 2017 Emergency Response Construction Project.

Areas downstream from the Phase 3 Repair Project area also may be indirectly affected by the flood risk management component of the project, through improved water quality and flood risk management conditions. The extent of this potential effect is difficult to quantify, however, for element IVc; construction of a setback levee and breaching a small downstream portion of the existing levee would be expected to create a backwater effect and would not result in a substantial widening of the flood plain. An analysis also was conducted to evaluate the hydraulic effects of the setback levee at element IVc. This hydraulic analysis showed that the proposed action would essentially have no effect on the maximum water surface elevation, with a computed maximum increase in the water surface elevation of 0.0007 feet, and maximum flow rate changes would be negligible during extreme events (100-year flood recurrence interval). Because far afield project-related hydrologic effects are not likely to occur, the action area is concluded to be in the immediate vicinity of the actual project boundaries.

ENVIRONMENTAL BASELINE

HYDROLOGY

SACRAMENTO–SAN JOAQUIN DELTA

The Delta extends inland from the confluence of the Sacramento and San Joaquin rivers west of Antioch to Sacramento on the Sacramento River and to near Mossdale on the San Joaquin River. The Phase 3 Repair Project area is in the southeastern portion of the Delta, within the legal boundary of the Delta as defined by Section 12220 of the California Water Code.

The legal Delta encompasses an area of approximately 851,000 acres (of which approximately 135,000 acres consist of waterway, marshland, or other water surfaces). The Delta is divided into a Primary Zone and a Secondary Zone, as defined by the Delta Protection Act of 1992. Land uses in the Primary Zone are regulated to protect the area for agriculture, wildlife habitat, and recreational uses. The Secondary Zone is the area outside the Primary Zone and within the legal Delta. Where urban development activities occur in the Secondary Zone, efforts should be taken to ensure that these activities do not adversely affect Delta waters, Primary Zone habitat, or recreational uses. The San Joaquin River delineates the boundary between the Primary Zone to the west and the Secondary Zone to the east. The Phase 3 Repair Project is located in the Secondary Zone.

The Sacramento River contributes roughly 75 to 80 percent of the Delta inflow in most years, and the San Joaquin River contributes about 10 to 15 percent; the Mokelumne, Cosumnes, and Calaveras rivers, which flow into the eastern side of the Delta, contribute the remainder. The rivers flow through the Delta and into Suisun Bay, San Pablo Bay, San Francisco Bay, and the Pacific Ocean. Historical annual Delta inflow averaged approximately 23 million acre-feet (MAF) between 1945 and 1995, with a minimum inflow of approximately 6 MAF in 1977 and a maximum of approximately 70 MAF in 1983. Water flowing into the Delta is used for urban and agricultural use, recreation, navigation, and wildlife and fisheries. The Delta provides drinking water for about 23 million Californians.

Freshwater inflows to the Delta vary greatly, depending on precipitation, snowmelt, and Central Valley Project (CVP) and State Water Project (SWP) water operations. During the summer months, most inflow to the Delta comes from regulated releases from SWP and CVP reservoirs. Both projects also withdraw large volumes of water from the Delta for agricultural and urban use. Precipitation in the project region occurs primarily from November through March, with the average annual precipitation ranging from about 8 inches near Tracy to approximately 17 inches near Lodi. Near Lathrop, the annual precipitation is approximately 12 inches.

Water movement in the Delta responds to four primary forcing mechanisms:

- freshwater inflows to the ocean;
- Delta exports and upstream diversions;
- operation of water control facilities such as dams, export pumps, and flow barriers; and
- the regular tidal movement of seawater into and out of the Delta.

In addition, winds and salinity behavior in the Delta can generate secondary currents that, despite being of low velocity, can be of considerable significance with respect to transporting contaminants and mixing different sources of water. Changes in flow patterns in the Delta, whether caused by export pumping, winds, atmospheric pressure, flow barriers, tidal variations, inflows, or local diversions, can influence water quality at drinking water intakes.

The Delta is a hydrologically complex region of interlacing channels, marshland, and islands. The Delta has been reclaimed into more than 60 islands and tracts, interlaced with about 700 miles of waterways. Some channels are edged with aquatic and riparian vegetation, but most are bordered by steep banks of earth or riprapped levees. Vegetation generally is removed from channel margins to increase flood flow capacity and facilitate levee maintenance. About 520,000 acres are devoted to farming. An approximately 1,100-mile network of levees protects the reclaimed land, most of which lies near or below sea level, from flooding. Some of the island interiors are as much as 25 feet below sea level.

Nearly 16.5 miles of the 19 miles of levees protecting RD 17 are considered federal project levees; the 2.6-mile dryland levee is not a federal levee. Federal project levees either were constructed by the federal government (typically through USACE) or were built by others and later brought under federal jurisdiction.

San Joaquin River

The San Joaquin River originates in the Sierra Nevada and enters the San Joaquin Valley at Friant Dam. Most of the flow in the lower San Joaquin River is derived from inflow from the Merced, Tuolumne, and Stanislaus rivers (Northeastern San Joaquin County Groundwater Banking Authority 2004). The 330-mile-long San Joaquin River, which drains a watershed area of 13,540 square miles from the Sierra Nevada to the Delta, contributes approximately 15 percent of the inflow to the Delta (Delta Protection Commission 2000). Flowing through portions of Fresno, Madera, Merced, Stanislaus, San Joaquin, Sacramento, and Contra Costa counties, the river has flows ranging from 1,500 cfs in dry years to more than 40,000 cfs in wet years (Friant Water Users Authority and Natural Resources Defense Council 2002).

Hydrologic conditions in the San Joaquin River basin are dominated by snowmelt from the Sierra Nevada. Before major water storage projects were completed on the San Joaquin River and its major tributaries, lower San Joaquin River flows generally peaked in late spring/early summer and dropped to low levels in the fall. Since completion of Friant Dam (1944), McClure Reservoir (1967 on the Merced River), Don Pedro Reservoir (1971 on the Tuolumne River), and New Melones Reservoir (1979 on the Stanislaus River), the lower San Joaquin River's seasonal flow pattern has changed substantially. Before 1944, based on 1923–1944 records, flow in the lower San Joaquin River tended to peak in May and June, with an average monthly flow of almost 11,000 cfs, and declined rapidly to an average monthly flow of approximately 1,200–1,300 cfs in August and September. Since 1979, the average monthly flow has peaked in March at just over 10,000 cfs, with a more gradual decline to approximately 2,400 cfs in August. In addition, the San Joaquin River is tidally influenced by the Delta and the San Francisco Bay. Tidal fluctuation in the San Joaquin River has been modeled to approximately the Vernalis tide gauge and the Airport Way crossing of the San Joaquin River, which is approximately 13 river miles upstream from the project site.

The SJRRP was established in late 2006, to implement the Stipulation of Settlement in *NRDC et al. v. Kirk Rodgers et al*. (Settlement). Authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act, included in PL 111-11. The goal of the SJRRP is to re-operate and increase the release of water from Friant Dam in accordance with the Settlement, and in a manner consistent with federal, State, and local laws, and future agreements with downstream agencies, entities, and landowners (Reclamation and DWR 2011). The Settlement establishes two primary goals:

- *Restoration Goal*—To restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish. To achieve the Restoration Goal, the Settlement calls for releases of water from Friant Dam to the confluence of the Merced River (referred to as Interim and Restoration Flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon.

- *Water Management Goal*—To reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim and Restoration Flows provided for in the Settlement. To achieve the Water Management Goal, the Settlement calls for recirculation, recapture, reuse, exchange, or transfer of the Interim and Restoration Flows to reduce or avoid impacts on water deliveries to all of the Friant Division long-term contractors caused by the Interim and Restoration Flows.

The SJRRP is to release Interim and Restoration Flows to the San Joaquin River from Friant Dam in accordance with the flow schedule presented in Exhibit B of the Settlement. The Settlement establishes the Recovered Water Account and recovered-water program, which make water available to all Friant Division long-term contractors who provide water to meet Interim or Restoration Flows so that the impacts of Interim and Restoration Flows on such contractors can be reduced or avoided.

LOCAL DRAINAGE

Stormwater runoff in the RD 17 area commonly is collected in agricultural ditches, channels, municipal stormwater sewers, or human-made ponds before being pumped to the San Joaquin River. Runoff from the area east of the San Joaquin River, along levee elements Ie and VIIb, is directed west through agricultural swales and ditches, and then is pumped into the river by means of private agricultural pumps. Runoff from developed lands adjacent to elements IVa, IVc, and VIa.4 is directed to the City of Lathrop's storm drainage system, held in detention basins, and ultimately pumped into the San Joaquin River through a municipal stormwater outfall. Runoff in the area around element VIIe, which encompasses the Oakwood Lake development, first flows into the artificial lake in the center of the development, and then is pumped into the river if lake levels become too high.

WATER QUALITY

Water quality in the Delta and portions of the San Joaquin River are heavily influenced by CVP and SWP operations. Generally, Delta water quality is best during the winter and spring months and poorer during the irrigation season and early fall. Water quality in the San Joaquin River is influenced by factors such as rain and snowmelt runoff, reservoir operations, and irrigation return flows in the San Joaquin river basin. Agricultural return flows commonly discharge elevated salt loads into the San Joaquin River. The SWRCB has set flow and water quality objectives at Vernalis, located just upstream from the Phase 3 Repair Project area. To meet the Vernalis objective, the U.S. Bureau of Reclamation supplements flows on the San Joaquin River with releases from New Melones Reservoir on the Stanislaus River (Northeastern San Joaquin County Groundwater Banking Authority 2004).

The latest version of the Section 303(d) list for California issued by the SWRCB (approved October 26, 2006) identifies an impaired status for waterways in the eastern Delta, including the lower San Joaquin River. Potential sources of pollution for all of the listed constituents in the basin include agriculture, urban runoff/storm sewers, resource extraction, and unknown sources. The eastern Delta, including the lower San Joaquin River, is on the Section 303(d) list for impairment from boron, chlorpyrifos, diazinon, dichlorodiphenyltrichloroethane, electrical conductivity, unknown toxicity, Group A pesticides, exotic species, and mercury. Downstream from the Phase 3 Repair Project area, the Stockton Deep Water Ship Channel is being addressed by a total maximum daily load (TMDL) plan for dissolved oxygen and is no longer on the Section 303(d) list. TMDLs have been initiated for organophosphorus pesticides (i.e., diazinon and chlorpyrifos), salinity and boron, and selenium in the lower San Joaquin River watershed and for total dissolved solids and mercury in Delta channels. TMDLs for the other listed pollutants are scheduled to be developed at various times over the next 10 years, in accordance with the priorities contained in the Section 303(d) list.

Major monitoring programs for the San Joaquin River include DWR's Municipal Water Quality Investigations Program and Water Rights Decision 1485 Water Quality Monitoring Program. The City of Stockton also monitors ambient water quality to assess potential effects of discharges from the Stockton Regional Wastewater Control Facility. Data are collected at five water quality monitoring sites along the San Joaquin River near the Phase 3

Repair Project area. The Mossdale Bridge sampling site at the Interstate 5 crossing over the San Joaquin River is near elements VIcde and VIIb. The Vernalis sampling site is located near the town of Vernalis, just upstream from the Phase 3 Repair Project area. Some of the broad categories that are monitored are discussed briefly below.

HABITAT

Dense riparian forests once flanked the San Joaquin River in this area. In contrast, the habitat today consists of linear areas and occasional remnant patches of riparian forests and related riparian scrub that grow on or adjacent to the levee, primarily on the waterside. A few larger areas of these riparian forests are present where the river turns away from the levee and creates a point bar and an upland floodplain area. Riprap or large boulders cover the lower half of most of the waterside of the San Joaquin River east levee in the Phase 3 Repair Project area, and ruderal vegetation grows in open areas, especially upslope from the riprap and on large open areas on the landside of the levee. Other areas of levee on the waterside are barren and/or covered with stumps and dead vegetation, likely because of levee maintenance that has included cutting scrub and low vegetation, burning, and applying herbicide. Some of the lands on the waterside of the levee are privately held and are affected by grazing and other landowner activities.

The landside reaches of the Phase 3 Repair Project area levees primarily are barren or covered with ruderal vegetation. Beyond the base of the levees, riparian vegetation is rare but occasionally is present in small, isolated patches. Other trees include occasional single or isolated stands of native oaks and nonnative trees that have been planted around farms, agricultural fields, and residential or other types of development. Habitat and land cover types present in the Phase 3 Repair Project area include riparian forests, nonnative woodlands, agricultural lands, ruderal and developed areas, and aquatic features (including marsh, wetlands, and ponds) (**Exhibits 13a** through **13c**).

VEGETATION AND LAND COVER

As described below, terrestrial vegetation and land cover types in the Phase 3 Repair Project area and vicinity include Great Valley cottonwood riparian forest (remnant), Great Valley oak riparian forest (remnant), nonnative woodland, agricultural (row crops, orchards, dirt roads, and irrigation ditches), and ruderal and developed (residential housing, parks, boat launch facilities, and roads).

- **Great Valley cottonwood riparian forest:** Remnant patches of Great Valley cottonwood riparian forest in the Phase 3 Repair Project area are dominated by large Fremont cottonwood (*Populus fremontii*) trees and Goodding's willow (*Salix gooddingii*). Most of the otherwise linear or smaller patchy areas of this community lack Fremont cottonwood and are represented by Goodding's willow, red willow (*S. laevigata*), arroyo willow (*S. lasiolepis*), narrow leaved-willow (*S. exigua*), scattered valley oak (*Quercus lobata*), Oregon ash (*Fraxinus* latifolia), and buttonbush (*Cephalanthus occidentalis*). Native ground cover species, found mainly in the larger remnant patches of riparian forest, include California blackberry (*Rubus ursinus*) and wild rose (*Rosa californica*). Common nonnative understory species found in most elements include Himalayan blackberry (*Rubus discolor*) and tree tobacco (*Nicotina glauca*). Most of the Great Valley cottonwood riparian forest community also could be characterized as Great Valley riparian scrub, which does not include Fremont cottonwood and is characterized by a shorter canopy and more uniform structure. This habitat, however, is part of the Great Valley cottonwood riparian forest that was extensive and connected along this entire reach of the San Joaquin River. Therefore, this BA describes all riparian habitat as such. The largest stands of Fremont cottonwood trees in the Phase 3 Repair Project area are present in elements IIIb, IVc, Va, and VIa.1.
- **Great Valley oak riparian forest:** Great Valley oak riparian forest is located in the Phase 3 Repair Project area, occurring only on the landside of the levees. This is a medium to tall (rarely to 100 feet), broadleaved, winter deciduous, closed-canopy riparian forest dominated by valley oak. Understories include scattered Northern California black walnut (*Juglans nigra*) and western sycamore (*Platanus racemosa*) as well as young valley oaks. Understory plants include California rose (*Rosa californica*), blackberry (*Rubus* spp.), and

western poison oak (*Toxicodendron diversilobum*) (Hickman 1993; Holland 1986). Two substantial oak groves of very large, healthy valley oak trees are present on the landside of elements IIIb and IVa and account for most of the Great Valley oak riparian forest. Several groups of smaller valley oak trees and individual valley oaks, scattered along the landside of other Phase 3 Repair Project elements, also contribute to this community.

- **Nonnative woodland:** Along the landside of elements Ie, VIa.1, VIde, and VIIg, nonnative trees have been planted around farms, agricultural fields, and residential or other types of development. These woodlands lack understory vegetation, other than grasses and ruderal vegetation.
- **Agricultural cropland:** Cropland in the Phase 3 Repair Project area is dominated by alfalfa fields, orchards, and row crops, such as tomatoes. Ruderal species grow along the edges of fields and irrigation ditches, some of which contain water and associated aquatic plants. The largest areas of agricultural lands are present in elements Va, VIa.1, and VIcde.
- **Ruderal vegetation:** Ruderal vegetation is characterized by nonnative weedy and sometimes invasive vegetation and nonnative annual grasses. Common weed species include yellow star-thistle (*Centaurea solstitialis*), black mustard (*Brassica nigra*), shortpod mustard (*Hirschfeldia incana*), Italian thistle (*Carduus pycnocephalus*), milk thistle (*Silybum marianum*), and Himalayan blackberry. Common grass species include ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum* ssp. *leporinum*), Bermuda grass (*Cynodon dactylon*), and Johnsongrass (*Sorghum halepense*). The levee slopes are dominated by ruderal vegetation. Large open areas in elements IIIa and IVc also are composed primarily of ruderal vegetation, as are smaller open areas in elements VIcde and VIIe that border roads, parking lots, and agricultural land.
- **Developed areas:** Developed areas in the Phase 3 Repair Project area consist of residential areas bordering elements IVa, IVc, Va and VIa.1, and VIIe; parks located in elements IVc and VIa.2, the latter of which is also a boat launching facility; and ranch houses and related facilities located in or adjacent to elements Ie, IIab, Va, VIa.1, and dryland levee element XI. Vegetation in residential areas and parks consists of turf grasses, landscape trees, and occasional valley oak trees. Ranch lands often contain English walnut trees (*Juglans regia*), a variety of landscaped trees, and occasional native valley oak trees.

AQUATIC HABITATS

The principal surface water bodies associated with the Phase 3 Repair Project area are the San Joaquin River and Walthall Slough. Project elements Ia through IVc are located downstream from the confluence of the San Joaquin River and Old River. Reach V is located directly adjacent to this confluence. Elements VIa.1 through VIIe are upstream from the confluence of the San Joaquin River and Old River. Small portions of elements VIIe and VIIg are located along Walthall Slough. An approximately 3.5-acre constructed pond is located adjacent to elements IIab, but outside the project footprint (**Exhibit 13a**).

In the Phase 3 Repair Project area, the San Joaquin River is characterized as a wide channel (approximately 300 feet) with little riparian canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. Altered flow regimes, flood risk management, and bank protection efforts along much of the San Joaquin River have reduced riparian vegetation and associated shaded riverine aquatic (SRA) habitat, sediment transport, channel migration and avulsion, and large woody debris recruitment, and have isolated the channel from its floodplain. This has resulted in a decline in habitat quality for fish species using the San Joaquin River near the Phase 3 Repair Project area. However, fish use this segment of the river, even if only as a migratory pathway to and from upstream spawning and rearing areas.

Wetland vegetation in the Phase 3 Repair Project area is limited to coastal and valley freshwater marshes, several agricultural ditches, and the edges of one constructed pond. Freshwater marsh is isolated in a depression on the landside of the levee in element Ib between Howard Road to the north and a dirt farm road on the south. A limited

amount of freshwater marsh also is present around the edges of a constructed pond, located on a large private estate and equestrian center, east of the Phase 3 Repair Project area levee in element IIab. A second area of freshwater marsh is located just outside the Phase 3 Repair Project area in element Va, and in an area of backwater on the San Joaquin River. Agricultural ditches are located along the edges of fields and orchards.

FISH POPULATIONS

The lower San Joaquin River and Delta serve as a migration corridor and/or provide other types of habitat (e.g., rearing, spawning) for steelhead, delta smelt, white sturgeon (*Acipenser transmontanus*), and green sturgeon. Numerous other resident native and nonnative species also are found in the San Joaquin River. Among the native species present in the river are blackfish (*Orthodon microlepidotus*), threespine stickleback (*Gasterosteus aculeatus*), and San Joaquin roach (*Lavinia symmetricus* sp.); while nonnative species include striped bass (*Morone saxatilis*), white catfish (*Ameiurus catus*), and bluegill (*Lepomis macrochirus*). In late 2014, experimental populations of spring-run Chinook salmon began to be reintroduced to the San Joaquin River, as a component of the SJRRP (see "San Joaquin River" subsection above).

The small, unnamed pond in elements IIab (**Exhibit 13a**) may contain fish and other aquatic species. Because of its isolated nature and size, this pond likely supports only nonnative warm-water fish that probably have been introduced. Typical fish that are found in similar ponds include bluegill, western mosquitofish (*Gambusia affinis*), and catfish (*Ameiurus* or *Ictalurus* spp.), among other nonnative warm-water species.

WILDLIFE

Common wildlife species expected in the Phase 3 Repair Project area are those typically associated with agriculture (e.g., alfalfa, row crops, and orchards) and ruderal habitat, which account for 57 percent of the Phase 3 Repair Project area's footprint. Species include California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), western harvest mouse (*Reithrodontomys megalotis*), and California meadow vole (*Microtus californicus*). These small mammals are prey for a variety of raptor species known to occur in the area, including Swainson's hawk (*Buteo swainsoni*). Riparian habitats in the Phase 3 Repair Project area provide nesting habitat for a wide variety of bird species.

SPECIES ACCOUNTS

This section presents species accounts for the federally listed species considered in this BA, including relevant life history and habitat use, as well as the species' potential for occurrence in the action area. The action area (see the "Action Area" section above) encompasses the entire area that may be affected by the Phase 3 Repair Project, including more distant locations where indirect effects may occur. However, the species accounts below focus on the habitat present in the Phase 3 Repair Project area itself and describe the potential for federally listed species to occur in the general vicinity. Only when the habitat quality or species distribution is specifically known for the action area is it described.

VALLEY ELDERBERRY LONGHORN BEETLE

VELB has four life stages: egg, larva, pupa, and adult. This species, which is federally listed as threatened, is nearly always found on or close to its host plant, the elderberry (*Sambucus* sp.). Females lay their eggs on the bark, and larvae hatch and burrow into the stems. The larval stage can last 2 years, after which the larvae enter the pupal stage and transform into adults. Adults are active (feeding and mating) from March to June (USFWS 2006). It appears that to function as VELB habitat, host elderberry shrubs must have stems that are 1.0 inch or greater in diameter at ground level. Use of the plants by the beetle rarely is apparent. Frequently, the only exterior evidence of the shrub's use by the beetle is an oval exit hole, created by the larva just before the pupal stage. Field studies conducted along the Cosumnes River and in the Folsom Lake area suggest that larval galleries can be found in elderberry stems with no evidence of exit holes, because the larvae either succumb before constructing an exit hole or are not far enough along in the developmental process to construct an exit hole (USFWS 1996a).

VELB is patchily distributed throughout the remaining riparian forests of the Central Valley, from Redding to Bakersfield, and appears to be only locally common (i.e., found in population clusters that are not evenly distributed across the Central Valley). Extensive loss of Central Valley riparian forests has occurred since 1900, with riparian forests declining by 80 to 96 percent, depending on the region (USFWS 2006). Although it is wide-ranging, VELB is thought to have suffered a long-term decline because of human activities that have caused widespread alteration and fragmentation of riparian habitats and, to a lesser extent, upland habitats that support the beetle. Low density and limited dispersal capability may cause the beetle to be particularly vulnerable to population isolation because of habitat fragmentation. Insecticide and herbicide use in agricultural areas and along road rights-of-way may be factors limiting the beetle's distribution. The age and quality of individual elderberry shrubs/trees and stands as a food plant for beetle may be a factor in its limited distribution.

Elderberry shrubs are known to occur along the San Joaquin River, on both the waterside and landside of levees in the Phase 3 Repair Project area. Focused surveys for elderberry shrubs were conducted along all levee reaches on March 8, 2011; the area was resurveyed on January 29, 2014. A total of 18 elderberry shrubs were observed within 100 feet of the Phase 3 Repair Project area: nine shrubs on the waterside of the levee and nine shrubs on the landside. None of the shrubs had evidence of beetle exit holes. One of the landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat. See **Exhibit 14** for locations of the elderberry shrubs that were observed within 100 feet of the Phase 3 Repair Project area during field surveys in 2014.

CRITICAL HABITAT

Critical habitat for VELB was designated at the time of listing. Two areas along the American River in the Sacramento metropolitan area were designated as critical habitat for this species. The Phase 3 Repair Project area is not located within designated critical habitat for VELB.

RECOVERY PLAN FOR VALLEY ELDERBERRY LONGHORN BEETLE

The Recovery Plan for Valley Elderberry Longhorn Beetle (USFWS 1984) lacks specific goals and does not include objective, measurable recovery criteria (USFWS 2006). The recovery plan identified additional essential habitat for this species in an area along Putah Creek, Solano County, and an area along the American River Parkway, Sacramento County. USFWS released a 5-year status review for VELB on October 2, 2006 (USFWS 2006). This review reported an increase in known beetle locations, from 10 at the time of listing in 1980 to 190 in 2006. Because of the presumed increase in the estimated population and the concurrent protection and restoration of several thousand acres of riparian habitat suitable for VELB, USFWS's status review determined that this species is no longer in danger of extinction and recommended that the species no longer be listed under the ESA. On October 2, 2012, the USFWS issued a proposed rule to delist VELB (78 FR 66058); however, on September 17, 2014, the USFWS withdrew this proposal, stating that the scientific information and analysis reflected in the October 2012 proposal was not strong enough to support a decision to delist the species (79 FR 55874).

RIPARIAN BRUSH RABBIT

Riparian brush rabbit, which is federally listed as endangered, inhabits riparian communities in the northern San Joaquin Valley that are dominated by thickets of willows and large clumps of shrubs and vines, such as wild rose, blackberries, coyote bush, and wild grape. Historically, riparian brush rabbit inhabited dense, brushy areas of valley riparian forests, marked by extensive thickets of wild rose, blackberries, and willows (Sandoval et al. 2006).

Suitable habitat for riparian brush rabbit is characterized by an abundance of woody ground litter, mats of low-growing vines and shrubs, and areas of higher ground not subject to regular or heavy flooding (Sandoval et al. 2006). On a seasonal basis, it also may use dense, tall stands of herbaceous plants adjacent to patches of riparian shrubs (Williams and Hamilton 2002). It tends to avoid large openings in the understory cover, frequenting only small clearings in the vegetation while foraging (USFWS 1998). An essential component of habitat for riparian brush rabbit is high-ground refugia from flooding, which provides protection from predators and dry habitat during prolonged rainstorms (USFWS 1998).

The only known populations of riparian brush rabbit are confined to Caswell Memorial State Park on the Stanislaus River in Stanislaus County, approximately 10 miles southeast of the Phase 3 Repair Project area, and in the South Delta along the San Joaquin River and overflow channels (Williams and Hamilton 2002; Williams et al. 2002; Lloyd and Williams 2003; Vincent-Williams et al. 2004; CDFW 2014) (**Exhibit 15**). The population in the South Delta is found in Paradise Cut along the rights-of-way of the two railroads that cross Paradise Cut and Tom Paine Slough, and in an oxbow on the San Joaquin River near Mossdale Landing (CDFW 2014). Riparian brush rabbits also have been found along the San Joaquin River north of the oxbow population, in waterside riparian habitat near the Phase 3 Repair Project area adjacent to elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1, and VIa.4 (CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004) (**Exhibit 15**). Other historical habitats along the San Joaquin River and tributaries are believed to no longer be suitable for riparian brush rabbits because of irrigated agriculture, livestock grazing, and impoundment and channelization of streams. High-ground refugia also may be lacking in these areas (Williams and Hamilton 2002).

In Paradise Cut, existing habitat for riparian brush rabbits is confined to levee bases, the channel banks of Paradise Cut, and pockets of low ground along the bottom of Paradise Cut. Generally, areas of suitable habitat in these locations are very narrow (15 to 100 feet wide). Most of the channels in Paradise Cut are in effect dead-end sloughs fed by Old River, with large portions containing water year-round, which results in the isolation of some upland areas (i.e., islands). The existing habitat for rabbits is covered in water on average once every 4 years, when flood flows in the San Joaquin River are sufficient to overtop Paradise Weir. Brush rabbits probably use the UPRR right-of-way as high-ground refugia during flooding events (Williams and Hamilton 2002).

Occupied habitat for riparian brush rabbit is documented adjacent to the Phase 3 Repair Project area along the waterside levee in elements IIIa and IIIb, between elements IIab and IIIa, and between elements VIa.1, and VIa.4. The waterside habitat along elements IIIa and IIIb is dominated by willow within interspersed California blackberry and grasses. The waterside habitat between elements IIab and IIIa is dominated by willows, cottonwoods, valley oaks, wild rose, and California and Himalayan blackberry. The waterside habitat between elements VIa.1 and VIa.4 is on an oxbow with dense riparian vegetation. Other patches of riparian vegetation along the San Joaquin River and adjacent to Phase 3 Repair Project area levees, such as the Great Valley cottonwood forest and Great Valley oak riparian forest communities shown in **Exhibits 13a** through **13c**, provide potentially suitable habitat for riparian brush rabbit, including the small areas of riparian habitat that are present on the waterside of Phase 3 Repair Project area elements IIab, IVc, and Va.

Riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover rather than in large openings. It feeds on herbaceous vegetation, such as grasses, sedges, clover, forbs, and buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). This species has a small home range and mainly remains hidden under protective shrub cover, seldom venturing more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.

Critical Habitat

Critical habitat has not been designated for riparian brush rabbit.

Recovery Plan for Riparian Brush Rabbit

The Recovery Plan for Upland Species of the San Joaquin Valley, California addresses the riparian brush rabbit (USFWS 1998). At the time the recovery plan was prepared, only the Caswell Memorial State Park population was known to exist. One of the most important conservation actions identified in the plan was establishment of other viable populations within the park's range. The recovery plan recommended the following actions (USFWS 1998):

- Initiate a reintroduction program that includes researching genetic diversity among remaining individuals.
- Implement a captive breeding program to translocate individuals to new populations.
- Establish at least three additional wild populations in the San Joaquin Valley in restored and expanded suitable habitat within the rabbit's historical range.

In 1999, the Endangered Species Recovery Program began implementing the Controlled Propagation and Reintroduction Plan for the Riparian Brush Rabbit (Williams et al. 2002), which was recommended in the Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998). The primary goal of the program is to prevent extinction by providing animals for reintroduction to establish new populations or augment existing populations. In July 2002, captive-bred rabbits were released at the San Luis National Wildlife Refuge, near Los Banos in the central San Joaquin Valley, and in 2005, a population of captive-bred rabbits was introduced to a private ranch along the San Joaquin River in Stanislaus County, adjacent to the San Joaquin River National Wildlife Refuge (USFWS 2007). This effort is ongoing.

DELTA SMELT

Delta smelt was formally listed as threatened under the ESA on March 5, 1993 (59 FR 440). On December 19, 1994 (59 FR 65256), USWFS designated critical habitat. Delta smelt is found only from Suisun Bay upstream through the Sacramento–San Joaquin estuary in Contra Costa, Sacramento, San Joaquin, Solano, and Yolo counties.

Delta smelt is endemic to the upper Sacramento–San Joaquin River estuary and occurs primarily in open surface waters of Suisun Bay, in the Sacramento River downstream from Isleton, and in the San Joaquin River downstream from Mossdale (Bennett 2005), including the project area. Its historic range is thought to have extended from Suisun Bay upstream to at least the city of Sacramento on the Sacramento River and Mossdale on the San Joaquin River. Delta smelt historically was one of the most common pelagic fish (fish living in open water away from the bottom) in the upper Sacramento–San Joaquin estuary (USFWS 2004). The delta smelt population generally is concentrated in the estuary west of the confluence of the Sacramento and San Joaquin rivers in high-outflow years and in the north Delta in low-outflow years (Sweetnam 1997, 1998; Bennett 2005). Delta outflow determines the location of the salinity gradient and may strongly influence delta smelt distribution. USFWS data indicate that delta smelt is found in the San Francisco Bay/Sacramento–San Joaquin Delta (Bay-Delta) estuary where salinity generally is less than two parts per thousand. Except when spawning in freshwater, delta smelt most frequently is caught in or is slightly upstream from the entrapment zone (Bennett 2005). In the CDFW Delta-wide 20mm delta smelt survey, delta smelt larvae were observed only occasionally and in very low abundance in the vicinity of the project area (less than four larvae in 10,000 cubic meters as sampled on April 4, 2014). The species was not observed in the project vicinity in 2015 or 2016, during the delta smelt monitoring program that occurs from January through March.

CRITICAL HABITAT

Although the Phase 3 Repair Project area is near the upper limit of the known distribution of delta smelt, it is included in the area designated as critical habitat for the species (Critical Habitat Determination for the Delta Smelt, 59 FR 65256, December 19, 1994). In the critical-habitat designation, USFWS identified the following primary constituent elements essential to conservation of delta smelt: physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration (59 FR 65256). The primary constituent elements are organized by habitat conditions required for each life stage. USFWS has identified specific areas in the Delta for spawning habitat, larval and juvenile transport, and adult migration for delta smelt. The Phase 3 Repair Project area and larger action area include places identified for larval and juvenile transport and adult migration, but do not include specific areas important for delta smelt spawning habitat (59 FR 65256).

RECOVERY PLAN FOR DELTA SMELT

The Sacramento–San Joaquin Delta Native Fishes Recovery Plan includes restoration of abundance and distribution of delta smelt (USFWS 1996b). Action items in the recovery plan for delta smelt refer to four zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of delta smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Repair Project area or action area.

LONGFIN SMELT

On April 2, 2012, the USFWS issued its finding that the longfin smelt warranted protection under the ESA, and added it as a candidate species for protection under the ESA (77 FR 19755). Longfin smelt is found in bay, estuarine, and nearshore coastal environments from San Francisco Bay north to Lake Earl near the Oregon border. The southernmost detection of the species was a single fish from Monterey Bay (Eschmeyer et al. 1983), although

spawning has not been documented south of San Francisco Bay. The San Francisco estuary and the Delta support the largest longfin smelt population in California. Longfin smelt is more broadly distributed throughout the Bay-Delta estuary and is found in water with higher salinities than delta smelt. Longfin smelt most often is concentrated in Suisun Bay, San Pablo Bay, and northern San Francisco Bay during nonspawning periods (Moyle 2002). No fish surveys have been conducted by RD 17 within the river stretch adjacent to the Phase 3 Repair Project area; however, CDFW's Delta-wide sampling program, including the 20mm delta smelt survey, longfin smelt larva survey, summer tow net survey, and spring Kodiak Trawl sampling, occurs in the vicinity of this area. Longfin smelt has a short life span, generally reaching maturity at 2 years of age, when it spawns and then dies. During the second year of life, adults tend to inhabit the higher salinity western portion of the estuary system; they occasionally have been found in nearshore ocean surveys (Rosenfield and Baxter 2007). Adults spend their lives in bays, estuaries, and nearshore coastal areas, and migrate into low-salinity or freshwater reaches of coastal rivers and tributary streams to spawn. Spawning occurs in the lower portions of the Sacramento and San Joaquin rivers and adjacent sloughs, typically between November and June, with peak spawning occurring from February through April (Baxter 1999; DWR 2009; Moyle 2002; Wang 1986). On the San Joaquin River, spawning occurs downstream from Medford Island, approximately 20 miles downstream from the project site (Moyle 2002). Locations and movements of all life stages of longfin smelt are influenced by a wide range of hydrologic and environmental variables (Rosenfield 2010), all of which show high variation among and within years; accordingly, temporal and spatial distributions of longfin smelt show high variation among and within years.

CRITICAL HABITAT

Because the longfin smelt has not been listed, no critical habitat has been designated.

RECOVERY PLAN FOR LONGFIN SMELT

The Sacramento–San Joaquin Delta Native Fishes Recovery Plan includes restoration of abundance and distribution of longfin smelt (USFWS 1996b). Action items in the recovery plan for longfin smelt refer to five zones in the Delta. Sampling stations within these zones were chosen to measure restoration because they have a record of longfin smelt catches and are sampled consistently. These zones do not include any portion of the Phase 3 Repair Project area or action area.

CENTRAL VALLEY STEELHEAD DISTINCT POPULATION SEGMENT

On March 19, 1998, NMFS listed the Central Valley steelhead DPS as threatened (63 FR 13347). Central Valley steelhead DPS is considered to be winter-run steelhead (McEwan and Jackson 1996). In the most recent 5-year review of the listing of this species, NMFS recommended that the Central Valley steelhead DPS should remain classified as a threatened species (NMFS 2011a). Findings of the next 5-year status review for all federally listed anadromous salmonids in the Central Valley are anticipated to be published in 2016. Like other anadromous salmonid species, this one matures in the ocean before entering freshwater on its spawning migrations. The major factor influencing steelhead populations in the San Joaquin River system is loss of habitat caused by construction of impassable dams on the mainstem and major tributaries.

Historically, Central Valley steelhead was found throughout the Sacramento and San Joaquin drainages, where waterways were accessible to migrating fish. Steelhead historically was present in the upper San Joaquin River basin, upstream from the current location of Friant Dam. Steelhead commonly migrated far up tributaries and into headwater streams where cool, well-oxygenated waters were present year-round.

Currently, in the Central Valley, viable populations of naturally produced steelhead are found only in the Sacramento River and its tributaries. Wild steelhead populations appear to be restricted to tributaries of the Sacramento River below Keswick Dam, such as Antelope, Deer, and Mill Creeks, and to the Yuba River below Englebright Dam (McEwan and Jackson 1996). No significant populations of steelhead remain in the San Joaquin

River basin; however, small persistent runs still occur on the Stanislaus and Tuolumne rivers, and perhaps the Merced River (McEwan and Jackson 1996).

Juvenile steelhead rear throughout the year and may spend 1 to 3 years in freshwater before emigrating to the ocean. Smoltification, the physiological adaptation that juvenile salmonids undergo to tolerate saline waters, occurs in juveniles as they begin their downstream migration. Smolting steelhead (age class 1+ and older) generally emigrate from March to June (Barnhart 1986; Reynolds et al. 1993).

The San Joaquin River near the Phase 3 Repair Project area is used by adult and juvenile steelhead primarily as a migration corridor between the ocean and cold-water habitat in the upstream tributaries. Juvenile steelhead would be likely to use the edges of rivers and sloughs, and floodplain habitats, if available, for rearing as they emigrate (Moyle 2002).

Critical Habitat

Critical habitat for the Central Valley steelhead DPS was designated on August 12, 2005; a final designation was published on September 2, 2005 (70 FR 52604), with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins. The Phase 3 Repair Project area is located within designated critical habitat for the Central Valley steelhead DPS.

Recovery Plan for Central Valley Steelhead Distinct Population Segment

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Although habitat conditions for Central Valley steelhead have improved slightly over the past decade, access to historic habitat generally remains blocked, and the quality of the species' remaining habitat generally remains degraded (Lindley et al. 2009; Cummins et al. 2008).

SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

The Sacramento River winter-run Chinook salmon was formally listed as threatened in November 1990 (55 FR 46515), and was reclassified as endangered under the ESA on January 4, 1994 (59 FR 440).

In the Delta, winter-run adults begin to move through the system in early winter (November–December), with the first upstream adult migrants appearing in the upper Sacramento River during late December (Vogel and Marine 1991, cited in NMFS 2003). Adult winter-run presence in the upper Sacramento River system peaks in March. The timing of migration may vary somewhat because of changes in river flows, dam operations, and water year type. Spawning occurs primarily from mid-April to mid-August, with peak activity occurring in May and June in the river reach between Keswick Dam and the Red Bluff Diversion Dam (Vogel and Marine 1991, cited in NMFS 2003).

Juvenile winter-run Chinook salmon occur in the Delta from October through early May, based on data collected from trawls, beach seines, and salvage records at State and federal water projects (DFG 1998). The peak of juvenile arrivals is between January and March. Juveniles tend to rear in the freshwater upper Delta areas for about the first 2 months (Kjelson et al. 1981, 1982). As they mature, winter-run Chinook fry and fingerlings prefer to rear farther downstream, where ambient salinity is up to 1.5 to 2.5 parts per thousand (Healey 1980, 1982; Levings et al. 1986). Fry remain in the estuary until they reach a fork length of about 118 millimeters (i.e., at 5 to 10 months of age). Emigration from the Delta may begin as early as November and continue through May (Fisher 1994; Myers et al. 1998).

With the exception of occasional strays, adult winter-run Chinook salmon generally do not occur in the San Joaquin River or in this portion of the Delta, and therefore, do not occur in the action area. The same is true for juvenile winter-run Chinook salmon.

Critical Habitat

Critical habitat for the winter-run Chinook salmon ESU was designated by NMFS on June 16, 1993 (58 FR 33212), with an effective date of July 16, 1993. Critical habitat is designated to include the Sacramento River from Keswick Dam (River Mile 302) to Chipps Island (River Mile 0) and all waters westward, including San Francisco Bay north of the Bay Bridge to the Golden Gate Bridge. The proposed action is not within designated critical habitat.

Essential Fish Habitat

EFH for Chinook salmon, which includes Sacramento River winter-run Chinook salmon ESU (NMFS 2014a), has been identified in the project and action areas. See the "Essential Fish Habitat" section of this BA.

Recovery Plan for Sacramento River Winter-Run Chinook Salmon Evolutionarily Significant Unit

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. In essence, improvement in the status of winter-run Chinook salmon ESU depends on re-establishment of an alternate population in a historically used area (e.g., Battle Creek) (Williams et al. 2011). Improvement of spring-run Chinook salmon ESU is dependent on improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects also are of primary importance in improving the status of this ESU (NMFS 2014b).

Recovery goals and restoration actions for Sacramento River winter-run Chinook salmon ESU are described by Williams et al. (2011) for the Sacramento River basin, including re-establishment of a population in a historically used area (e.g., Battle Creek) and fish passage improvement projects. Recovery goals do not, however, apply to the action area, because reintroduction of winter-run Chinook salmon is not planned for the San Joaquin River Basin.

CENTRAL VALLEY SPRING-RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

NMFS listed Central Valley spring-run Chinook salmon as threatened on September 16, 1999 (50 FR 50394).

Central Valley spring-run Chinook salmon historically was the most abundant run of Central Valley Chinook salmon (Fisher 1994). It occupied the headwaters of all major river systems in the Central Valley, where no natural barriers existed. Adults returning to spawn ascended the tributaries to the upper Sacramento River, including the Pit, McCloud, and Little Sacramento rivers. They also occupied Cottonwood, Battle, Antelope, Mill, Deer, Stony, Big Chico, and Butte creeks and the Feather, Yuba, American, Mokelumne, Stanislaus, Tuolumne, Merced, San Joaquin, and Kings rivers. Spring-run Chinook salmon migrated farther into headwater streams, where cool, well-oxygenated water was available year-round.

Surveys indicate that populations of remnant, non-sustaining spring-run Chinook salmon may be found in Cottonwood, Battle, Antelope, and Big Chico creeks (DWR 1997); more sizable, consistent runs of naturally produced fish are found only in Mill, Deer, and Butte creeks (Williams et al. 2011). All these creeks are tributaries in the Sacramento River basin. The Feather River Fish Hatchery sustains the spring-run population on the Feather River, but the genetic integrity of that run is questionable (DWR 1997). Although all of these populations are found in the Sacramento River basin, the ESU boundary of Central Valley spring-run Chinook salmon includes populations spawning in the Sacramento River and San Joaquin River basins, as reflected in the current 5-year status review (Williams et al. 2011; NMFS 2011b). The status of Central Valley spring-run Chinook salmon ESU likely has not improved since the 2005 status review (Williams et al. 2011). Improvement of spring-run Chinook salmon ESU is dependent on improving habitat conditions in spawning and rearing areas (Williams et al. 2011). Fish passage projects also are of primary importance in improving the status of this ESU (NMFS 2014a). Current and future efforts to restore production in the San Joaquin River are either being planned or are just beginning, and no results about their current efficacy are available.

Like winter-run Chinook salmon, adult spring-run Chinook salmon (other than occasional strays) generally have not occurred in the San Joaquin River basin, and therefore, do not occur in the action area. The same is true for juvenile spring-run Chinook salmon.

Critical Habitat

Critical habitat for the Central Valley spring-run Chinook salmon was designated on August 12, 2005; a final designation was published on September 2, 2005, with an effective date of January 2, 2006 (70 FR 52487). Critical habitat is designated to include selected waters in the Sacramento River basin from approximately Redding (River Mile 302) to approximately Chipps Island (River Mile 0) at the westward margin of the Delta and includes the Sacramento River. The Phase 3 Repair Project area is located outside the species' designated critical habitat.

Essential Fish Habitat

EFH for Chinook salmon, which includes Central Valley spring-run Chinook salmon ESU (NMFS 2014a), has been identified in the project and action areas. See the "Essential Fish Habitat" section of this BA.

Recovery Plan for Central Valley Spring-Run Chinook Salmon Evolutionarily Significant Unit

A recovery plan for the ESUs of Sacramento River winter-run Chinook salmon, the Central Valley spring-run Chinook salmon, and the DPS of Central Valley steelhead was prepared by NMFS in July 2014 (NMFS 2014b). The draft plan describes key threats and identifies recovery strategies and actions to achieve goals and objectives. Recovery goals and restoration actions are outlined for the Sacramento River basin and do not apply to the action area.

As discussed above in the "San Joaquin River" subsection of the "Environmental Baseline" section, one of the goals of the SJRRP is "to restore and maintain fish populations in 'good condition' in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish" (Reclamation and DWR 2011). The Settlement stipulates reintroduction of spring-run and fall-run Chinook salmon, with a priority given to restoring self-sustaining populations of wild spring-run Chinook salmon.

NORTH AMERICAN GREEN STURGEON DISTINCT POPULATION SEGMENT

On April 7, 2006, NMFS listed the Southern DPS of the North American green sturgeon as threatened under the ESA. In North America, green sturgeon is found from Ensenada, Mexico to southeast Alaska. The Southern DPS includes individual reproductive populations south of the Eel River. The populations north of the Eel River, grouped as the Northern DPS, currently do not warrant listing.

Green sturgeon is found in the lower reaches of large rivers, including the Sacramento–San Joaquin River basin, and in the Eel, Mad, Klamath, and Smith rivers. Green sturgeon adults and juveniles are found throughout the upper Sacramento River, as indicated by observations incidental to winter-run Chinook monitoring at Red Bluff Diversion Dam in Tehama County (Poytress et al. 2013; NMFS 2005). Green sturgeon spawns predominantly in the upper Sacramento River and is found primarily in the mainstem Sacramento River.

The green sturgeon is a primitive, bottom-dwelling fish, characterized by its large size (up to 7 feet long and 350 pounds), with a long, round body and “scutes” or plates along its dorsal and lateral sides. It is known to migrate up to 600 miles between freshwater and salt water environments and commercially is caught in the Columbia River and coastal Washington (PFMC 2003). Like all sturgeon species, it is anadromous, but it also is the most marine-oriented of the sturgeon species (NMFS 2005). It spends most of its life in salt water and returns to spawn in freshwater. Individuals congregate in the bays of these systems in summer, while some may travel upstream to spawn in spring and summer. Adult Southern DPS green sturgeon enter San Francisco Bay in late winter through early spring and spawn from April through early July, depending on water flow and temperature (Heublein et al. 2009).

The Southern DPS of the North American green sturgeon is slow growing and late maturing, reaching sexual maturity at about 15 years, at a length of about 5 feet, and typically spawning every 3 to 4 years (NMFS 2015). Green sturgeon spawning has been documented only in the Klamath, Sacramento, and Rogue rivers during recent times (NMFS 2005), although a spawning event was documented in 2011 in the lower Feather River at the Thermalito Afterbay Outlet (Seesholtz et al. 2014). Green sturgeon spawning in the San Joaquin River is not documented, as reported in the 5-year species status review for the Southern DPS of the North American green sturgeon (NMFS 2015).

Green sturgeon populations in the Southern DPS have relatively small population sizes, potentially have lethal temperature limits, face entrainment by water projects and influences of toxic material and exotic species, and may be susceptible to catastrophic events. Impassable barriers to spawning grounds are an additional threat. Preliminary Southern DPS population size estimates are being provided from Dual Frequency Identification Sonar surveys of aggregating sites in the upper Sacramento River; surveys conducted between 2010 and 2014 indicated an annual range of 164 to 526 spawning adults (personal communication with Ethan Mora, UC Davis, March 30, 2015, reported in NMFS 2015). Based on an estimate of mean spawning periodicity, as many as 1,348 ± 524 adults are estimated in the Southern DPS (personal communication with Ethan Mora, UC Davis, May 6, 2015, reported in NMFS 2015).

Green sturgeon may occur in the San Joaquin River between Stockton and the Highway 140 bridge (IEP 2013), including in the Phase 3 Repair Project area, although no evidence exists of historical use of the San Joaquin River by green sturgeon (BRT 2005; Beamesderfer et al. 2007). No documentation is known for green sturgeon spawning in the San Joaquin River, but spawning may have occurred before construction of large-scale hydropower and irrigation development (Mora et al. 2009). White sturgeon persist in the San Joaquin River at population levels of 10 percent of Sacramento River population levels. Young green sturgeon have been taken occasionally in the Santa Clara Shoal area in the Delta, but these fish likely originated in the Sacramento River (NMFS 2005).

Critical Habitat

Critical habitat for Southern DPS of North American green sturgeon was designated on October 9, 2009 (74 FR 52300). Critical habitat is designated to include select waters in the Sacramento and San Joaquin River basins, including the segment of the San Joaquin River in the action area.

Recovery Plan for North American Green Sturgeon Distinct Population Segment

A recovery plan has not been developed for green sturgeon, but the Federal Recovery Outline for the Southern DPS of the North American green sturgeon is available (NMFS 2010).

DIRECT AND INDIRECT EFFECTS ON SPECIES IN THE ACTION AREA

Under the ESA, direct effects are those that are caused by the project and occur at the same time as the action (e.g., construction-related effects). Indirect effects are those that are caused by the proposed action and are later in time but are reasonably certain to occur and there is a causal relationship with the action (e.g., operational effects). In other words, there is a logical, unbroken, traceable, explainable, predictable, chain of effects that results in, or "causes" a given effect on listed species. Avoidance and minimization measures for both direct and indirect effects are presented in the "Avoidance and Minimization Measures" section above. This section includes an evaluation of direct and indirect effects related to both the Phase 3 Repair Project (see "Effects Related to the Phase 3 Repair Project Actions" subsection) and the 2017 Emergency Response Construction Project (see "Effects Related to the 2017 Emergency Response Construction Project Actions" subsection).

EFFECTS RELATED TO THE PHASE 3 REPAIR PROJECT ACTIONS

VALLEY ELDERBERRY LONGHORN BEETLE

No known documented occurrences exist of VELB in the Phase 3 Repair Project area, but the species could use elderberry shrubs in the action area. Elderberry shrubs that could support beetles are sparsely scattered throughout the action area, along both the waterside and landside of the San Joaquin River levee.

Eighteen elderberry shrubs are present in or adjacent to the footprint of the Phase 3 Repair Project. The nine elderberry shrubs located along the waterside of the Phase 3 Repair Project levees would be avoided and protected during construction (see "Avoidance and Minimization Measures—Valley Elderberry Longhorn Beetle"). The nine elderberry shrubs located along the landside of the levee would require removal to accommodate construction of the Phase 3 Repair Project's seepage berms, cutoff walls, and setback levee (**Exhibit 14**). However, one of these landside shrubs does not have stems greater than 1 inch in diameter at ground level; therefore, it is not considered suitable VELB habitat.

The eight elderberry shrubs on the landside of the levee that have stems that are greater than 1 inch in diameter at ground level do not have evidence of beetle exit holes. These shrubs would require removal during construction of the Phase 3 Repair Project, resulting in direct effects on VELB. If the stems are occupied by beetles, any early-stage individuals are likely to be killed when the shrub is removed. Complete loss of the shrubs to be removed should be avoided by transplanting during the shrubs' dormant season; however, transplanted elderberry shrubs can experience stress or health problems because of changes in soil, hydrology, microclimate, or associated vegetation, and mortality of transplanted shrubs would preclude their future use by the beetle. Removing shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected; alternately, adverse effects on elderberry shrubs could have an overall effect on the beetle, even if larvae are absent at the time of impact, if the shrubs are relied on for reproduction.

The Phase 3 Repair Project would result in the removal of approximately 3.03 acres of riparian habitat (i.e., Great Valley cottonwood riparian forest and Great Valley oak riparian forest) associated with elderberry shrubs within elements IIIa, IIIb, IVa, Va, and VIa.1. Although some of the elderberry shrubs in these elements would not be removed, the removal of the associated riparian habitat could adversely affect the VELB metapopulation in this area by increasing the distance between occupied and unoccupied patches of habitat, and decreasing the likelihood of successful colonization of unoccupied habitat as a result of habitat fragmentation.

The eight elderberry shrubs that cannot be avoided would be transplanted to the levee setback area in element IVc (**Exhibit 12**). The restoration design, as outlined in the Conceptual MMP (**Appendix E**), would include elderberry seedlings and associated species plantings to compensate for the effects to VELB habitat in the Phase 3 Repair Project area. The Phase 3 Repair Project would include restoration of at least 9.9 acres of riparian forest and riparian scrub habitat in the setback area at element IVc (**Exhibit 12**). The expansion and restoration of riparian habitat in element IVc would augment the waterside riparian corridor along the San Joaquin River. The restored riparian scrub habitat (up to 6.1 acres) would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, comparable to the composition of existing habitats along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee would remain in place, and up to 5 acres of Great Valley oak woodland would be established along either side of it, thus providing an area above high-water events that is more ideal for elderberry shrubs. The restoration of approximately 9.9 acres (and up to 11.1 acres) of riparian forest and scrub habitat would achieve a 3:1 restoration to impact mitigation ratio (for effects on elderberry shrubs and associated habitat).

It can take 5 or more years for replacement elderberry plantings to reach a size conducive to use as VELB habitat. Therefore, a temporary loss of habitat available to the beetle would occur. The Phase 3 Repair Project would comply with avoidance and minimization measures described for VELB and would compensate for removal of these stems, in accordance with the VELB Framework (USFWS 2017), through the establishment of up to 9.9 acres of riparian forest and riparian scrub habitat. A net reduction in the number of elderberry shrubs would be avoided by transplanting the 8 elderberry shrubs.

After construction of the Phase 3 Repair Project, RD 17 would continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which would include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). Trees only would be trimmed, not removed, under these practices. Therefore, no change would occur in the number of elderberry shrubs along the RD 17 levees.

Riparian Brush Rabbit

As shown in **Table 5**, the Phase 3 Repair Project levee improvements would result in the removal of 3.31 acres of landside riparian habitat—specifically Great Valley cottonwood riparian forest and Great Valley oak riparian forest—that is suitable for riparian brush rabbit. This riparian habitat is located on the landside of the levee, where levee improvements (e.g., chimney drains, seepage berms) would be constructed. In general, most of the landside riparian vegetation is sparse and lacks understory vegetation other than grasses and ruderal vegetation, which would act as cover for riparian brush rabbit and would not be suitable for this species (Hansen, pers. comm., 2011). However, potential exists for some of these landside woody habitats to support suitable habitat for riparian brush rabbit, particularly because they are located adjacent to waterside riparian habitats that either are known to be occupied by this species or are highly suitable habitat. All landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied or highly suitable for riparian brush rabbit (i.e., elements IIab through element VIe). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the UPRR tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species. No waterside woody or riparian habitat would be removed because of levee improvement activities.

Nearly 54 acres of ruderal annual grassland also would be affected by Phase 3 Repair Project implementation. All effects on ruderal annual grassland that would result from levee improvements are assumed to be temporary because annual grassland would be reestablished in these areas after project completion. Although riparian brush rabbit may use annual grassland as a source for foraging habitat, the key component of habitat suitability for this species in the Phase 3 Repair Project area is based on the presence of riparian woody vegetation and not the surrounding grasslands. Riparian brush rabbit forages along the edges of shrub cover and in small clearings in the vegetation cover, rather than in large openings, feeding on herbaceous vegetation, such as grasses, sedges, clover, forbs, buds, bark, and leaves of woody plants (Sandoval et al. 2006; USFWS 1998). Furthermore, because this species is known to have a small home range and seldom ventures more than 1 meter (3.3 feet) from cover (Sandoval et al. 2006), the riparian brush rabbit likely uses only a small component of the grassland, and its use of such habitat is concentrated along the edges of the riparian areas.

Table 5
Effects of Implementing the Phase 3 Repair Project on Suitable Riparian Brush Rabbit Habitats

	Acres of Directly Affected Suitable Habitat
Waterside woodlands[1]	0.00
Landside woodlands[1,2]	3.31
Total	**3.31**[3]

Notes:
[1] Suitable riparian brush rabbit habitats are characterized as Great Valley cottonwood riparian forest and Great Valley oak riparian forest.
[2] Most of the landside riparian vegetation is sparse and lacks understory and is not suitable for this species (Hansen, pers. comm., 2011). However, any landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied by or highly suitable for riparian brush rabbit (i.e., elements IIab through elements VIe). North of elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.
[3] Of this, 1.61 acres were removed in elements IIIb, IVa, Va, VIa.1, and VIbcde during implementation of 2017 Emergency Response Construction Project in April 2017.
Source: Data compiled by AECOM in 2014; Updated by GEI Consultants, Inc. 2017

RD 17's ongoing practice for vegetation encroachment management is limited to trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up 5 feet above the ground or 12 feet above the crown road. Thus, trees and shrubs are only trimmed, not removed, because of this maintenance practice. Thus, RD 17's long-term management of vegetation encroachments on the landside and waterside of the levee is not expected to result in reduction or change to existing riparian habitat. The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed because of Phase 3 Repair Project construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed because of Phase 3 Repair Project construction (3.31 acres; see **Table 5**), but none would be removed because of future vegetation management activities.

The loss of potential riparian brush rabbit habitat in the Phase 3 Repair Project area could restrict the range of this species because the RD 17 area currently contains the northernmost known extent of the population on the San Joaquin River. It also could isolate other populations residing in residual habitats in the project vicinity. However, the proposed conservation measures (see the "Avoidance and Minimization Measures" section above) would minimize direct loss of riparian habitat in conjunction with compensation for adverse effects. Implementing such measures is anticipated to avoid a net reduction in the number of riparian brush rabbit and its associated habitat. The Phase 3 Repair Project would include restoration of at least 9.9 acres of riparian scrub habitat and upland refugia in the setback area at element IVc (**Exhibit 12**). The expansion and restoration of riparian habitat in element IVc would augment the waterside riparian corridor along the San Joaquin River and would provide additional riparian habitat opportunities for the riparian brush rabbit between two known occurrences of this species (i.e., between elements IIIa/IIIb and elements VIa.1/VIa.4 [CDFW 2014; Lloyd and Williams 2003; Vincent-Williams et al. 2004]). The restored riparian scrub habitat (up to 6.1 acres) would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, comparable to the composition of habitats where riparian brush rabbit is documented to occur along the RD 17 levees. Apart from a 400-foot section along the north side, the existing levee would remain in place, and up to 5 acres of Great Valley oak woodland would be established along either side of it, thus providing upland refugia for the riparian brush rabbit during high-water events. The restoration of approximately 9.9 acres (and up to 11.1 acres) of suitable habitat for riparian brush rabbit would achieve a 3:1 restoration to impact mitigation ratio (for effects on potential riparian brush rabbit habitat).

FEDERALLY LISTED FISH SPECIES

Fish species/ESUs addressed in this BA would likely use similar habitat in the action area. Therefore, the direct and indirect effects on delta smelt, longfin smelt, Central Valley steelhead, and green sturgeon are discussed together. Effects on Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon, which are unlikely to occur in the action area but may occasionally occur as strays, would be similar.

TEMPORARY CONSTRUCTION-RELATED EFFECTS

The Phase 3 Repair Project would include constructing several cutoff walls, which would entail degrading the top one-third to one-half of the levee, beginning with a 1:1 cut at the waterside crown. Implementing cutoff walls as part of the Phase 3 Repair Project would disturb soils along the top of the levee, which could enter the San Joaquin River through wind and water erosion. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately could be pumped into the San Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff. Waters (1995) evaluated the effects of turbidity and siltation in waterways at various exposure levels. Prolonged exposure to high levels of suspended sediment could create a loss of visual capability in fish, leading to a reduction in feeding and growth rates, and to a thickening of the gill epithelia, which may cause the loss of respiratory function; clogging and abrasion of gill filaments; and increases in stress levels, reducing the tolerance of fish to disease and toxicants (Waters 1995). Also, high levels of suspended sediments could cause the movement and redistribution of fish populations or other aquatic organisms, and could affect physical habitat (Waters 1995). Sediment loading could interfere with photosynthesis of aquatic flora and displace aquatic fauna. Many fish and other aquatic species are sight feeders, and turbid waters would reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, could become disoriented and leave areas where their main food sources are located, ultimately reducing their growth rates. Increased turbidity and sedimentation cause fish to avoid an area, thus reducing available habitat. Fish will not occupy areas unsuitable for survival unless they have no other option. Therefore, construction-related erosion could result in elevated river turbidity in critical species-specific and life stage-specific habitats, potentially precluding a species from occupying that habitat. In addition, the potential would exist for contaminants (such as bentonite slurry, fuels, oils, and other products used in construction) to be introduced into the waterway directly or through surface runoff. Contaminants may be toxic to fish, or may alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival.

The construction of some cutoff walls, specifically those in Elements Va and VIa.1, is anticipated to occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance, when necessary. Artificial lighting on the river has the potential to disrupt fish behaviors and increase predation risk. However, lights used during nighttime construction hours would be shielded and directed away from the waterside levees; therefore, adverse effects to fish as a result of nighttime lighting would be avoided.

Low frequency vibration from construction equipment has the potential to result in adverse effects to fish behaviors, even when ground disturbance and construction activities are located well away from the water's edge. Vibratory compaction equipment will be specifically restricted on the RD 17 levees, and the limited amount of compaction that would occur on landside chimney drain locations – specifically at Elements Ia and VIIg – would be restricted to normal work day hours, outside of sunrise and sunset hours in order to avoid peak foraging and migration timing. Therefore, adverse effects to fish as a result of vibration from construction equipment would be avoided and minimized.

Through implementation of the lighting and vibration measures, water quality BMPs, including a SWPPP, and BMPs for slurry management and a slurry spill contingency plan, the proposed conservation measures (see the

"Avoidance and Minimization Measures" section in this BA) would avoid direct and indirect take of fish during construction. The Phase 3 Repair Project would not be expected to have an effect on the overall continued existence and survival of these species.

PERMANENT CONSTRUCTION-RELATED EFFECTS

Most waterside woodlands in the Phase 3 Repair Project area are assumed to provide SRA habitat functions. Apart from the placement of 0.64 acre of riprap above the HTL along the waterside levee along 740 linear feet at element IVc, the Phase 3 Repair Project would not include performing any work on the waterside of the levee, and no waterside woodlands or SRA habitat would be removed. Therefore, construction-related effects on the habitats of federally listed fish species would be limited to minor disturbance of the waterside levee at three locations that are above the HTL and characterized by ruderal vegetation.

RD 17 would continue its ongoing practice for managing vegetation encroachments on the landside and waterside of the levee, which would include trimming trees within the levee prism on the landside and waterside slopes, and within 15 feet of the landside and waterside toes, from the ground up to 5 feet above the ground (or 12 feet above the crown road). Because vegetation management would be limited to trimming trees, no trees would be removed; thus, no change would occur in the amount of waterside habitat that would be directly affected and removed because of future vegetation management activities.

The amount of waterside woodlands outside the project footprint but located along the waterside of the levee to 15 feet out from the waterside levee toe of the project levee reaches is approximately 6.87 acres; none of this vegetation would be removed because of construction or future vegetation management practices. The amount of landside woodlands outside the project footprint but located along the landside of the levee to 15 feet out from the landside levee toe is approximately 5.92 acres; some of this would be removed because of Phase 3 Repair Project construction (3.31 acres; see **Table 5**) but none would be removed because of future vegetation management activities.

Because all Phase 3 Repair Project construction activities would occur above the HTL and no SRA habitat would be removed during Phase 3 Repair Project construction or future vegetation management activities, the Phase 3 Repair Project would not result in adverse effects on Central Valley steelhead, Delta smelt, longfin smelt, Sacramento River winter-run and Central Valley fall- and spring-run Chinook salmon, or green sturgeon.

BENEFITS OF PROJECT ACTIONS TO REARING SALMONIDS

The construction of a 1,100-foot-long setback levee with cutoff wall and seepage berm on a major oxbow of the San Joaquin River (see **Table 2**) would directly benefit fish resources. A Conceptual MMP has been prepared to describe the planned expansion and restoration of riparian habitat that would occur in element IVc (**Appendix E**). This riparian habitat is designed to primarily benefit the riparian brush rabbit; however, this habitat would be secondarily beneficial to fish species.

Approximately 0.64 acre (740 linear feet) of riprap would be installed on the waterside of the existing levee (above the HTL), where it would intersect the setback levee. After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 8 acres of floodplain to the river. That floodplain area would be graded to allow complete drainage of the floodplain to the river through the downstream opening in the remnant levee, as river flows recede. This would minimize the possibility of fish stranding. The other major benefit to fish resources would be the creation of approximately 8 acres of floodplain rearing habitat for juvenile salmonids, in particular, but also to other native fishes. The seasonal nature of inundation, along with complete drainage, would preclude establishment in the floodplain of predatory, non-native fishes. As stated in "Setback Levee with Seepage Berm and Underlying Cutoff Wall" subsection of the "Description of the Proposed Action" section, the Conceptual MMP (**Appendix E**) describes a framework for long-term and adaptive management strategies within the floodplain offset area. Long-term management actions for the riparian habitat area are expected to be minimal. In the event that maintenance is required to address site conditions, maintenance activities would avoid and minimize impacts to riparian vegetation and species habitat. The specific elevation of the levee breach invert elevation is under consideration. The primary purpose of the setback levee would be to provide habitat for the riparian brush rabbit. The invert elevation and the floodplain elevation would be based on site constraints, habitat requirements, and balancing the needs of riparian brush rabbit to provide protection to any individuals during high-water events while providing a level of disturbance that would support riparian scrub habitat in a sustainable way. The levee breach invert is expected to be set at an elevation to inundate approximately every 3 to 4 years, and the lower floodplain would inundate approximately every 6 years. A detailed hydraulic analysis of the surface water hydrology anticipated within the levee setback area, based on three possible levee breach invert elevations, is provided in the Conceptual MMP (**Appendix E,** see "Mitigation Site Baseline, Hydrology," and **Appendix B**). The floodplain habitat would not be permanently inundated and would not be connected to the San Joaquin River during the dry season.

Jeffries et al. (2008) reared juvenile Chinook salmon in enclosures for two consecutive flood seasons within various habitats of the Cosumnes River and its floodplain, to compare fish growth in river channel and floodplain habitats. Significant differences in growth rates were found; salmon reared in seasonally inundated habitats with annual terrestrial vegetation experienced higher growth rates than those reared in a perennial pond on the floodplain. Furthermore, riverine fish growth upstream from the floodplain varied with flow in the river; with little growth and high mortality during high-water events. When stream flows were low and clear, fish growth was rapid. Growth rates were poor in tidally influenced riverine habitat below the floodplain, where juveniles commonly were displaced during high-water events because of a lack of in-channel complexity. Overall, ephemeral floodplain habitats supported higher growth rates for juvenile Chinook salmon than more permanent habitats in either the floodplain or river. Variable responses in both growth and mortality, however, indicate the importance of providing habitat complexity for juvenile salmon in floodplain reaches of streams, so fish can find optimal places for rearing under different flow conditions. Habitat complexity allows juvenile salmon to find cover, thereby reducing the risk of predation from avian and piscine predators. While there is some potential for wading birds to prey upon juvenile salmon, which may use the expanded floodplain when it is periodically inundated (approximately every 6 years), the habitat structure is expected to provide cover for the salmon. As a result of the high flows necessary to inundate the setback area, it is anticipated that there will be a reduction in water clarity (increased turbidity), which would further reduce avian predation.

Floodplain and other off-channel habitat restoration are important for improving production of juvenile salmonids in California's Central Valley. Juvenile salmonid emigration generally is passive during high-water events (Healey 1980; Kjelson et al. 1981); they essentially are entrained in the water column until they encounter slower water velocities, where active swimming becomes possible. The San Joaquin River, like most rivers in the Central Valley, is incised and lacks channel complexity. With the exception of the Yolo Bypass for the Sacramento River (Sommer et al. 2001), juvenile salmonids frequently are displaced downstream to the intertidal Delta, where growth is diminished during high-water events in systems that lack access to floodplains. However, protected floodplain habitat provides important velocity refuge, and rearing and foraging habitat during peak emigration timing.

High San Joaquin River outflows generally occur during winter and early spring months. Juvenile spring-run Chinook and steelhead outmigration occurs at least partially during this period, while green sturgeon outmigration typically occurs later.

- Central Valley spring-run Chinook salmon juvenile outmigration generally occurs from April through June.
- Central Valley steelhead juvenile outmigration generally occurs from December through March in the San Joaquin River, and continues through June in the Delta.
- North American green sturgeon outmigration of older juveniles generally occurs from June through September.

The presence of the protected floodplain likely would benefit juvenile Chinook salmon and steelhead during high-water events. The configuration of the floodplain would promote use by juvenile salmonids during high flow events as they are directed into the floodplain through backflow currents.

Sommer et al. (2001) provided evidence that the Yolo Bypass, the primary floodplain of the lower Sacramento River, provides better rearing and migration habitat for juvenile Chinook salmon than adjacent river channels. During 1998 and 1999, salmon increased in size substantially faster in the seasonally inundated agricultural floodplain than in the river, suggesting better growth rates. Similarly, coded-wire-tagged juveniles released in the floodplain were substantially larger at recapture and had higher apparent growth rates than those concurrently released in the river. Improved growth rates in the floodplain were in part because of substantially higher prey consumption, reflecting greater availability of drift invertebrates. Bioenergetic modeling suggested that feeding success was greater in the floodplain than in the river, despite increased metabolic costs of rearing in the substantially warmer floodplain. Growth, survival, feeding success, and prey availability were higher in 1998 than in 1999, a year in which flow was more moderate, indicating that hydrology affects the quality of floodplain rearing habitat. These findings support the predictions of the flood pulse concept and provide new insight into the importance of the floodplain for salmon.

Work by Jeffries et al. (2008) and Sommer et al. (2001) indicate that off-channel floodplain habitats provide substantially improved rearing habitat, supporting higher growth rates than the intertidal river channel. However, their work shows that providing habitat complexity for juvenile salmon in floodplains is of utmost importance, so fish can find optimal places for rearing under varying flow conditions. It is well documented that survivorship to adulthood is increased when young salmonids leave freshwater at a larger size (Unwin 1997; Galat and Zweimuller 2001). Studies by Jeffries et al. (2008), Sommer et al. (2001), and others show that floodplain habitat restoration in Central California has major benefits to Chinook salmon populations, especially relative to growth and production. These studies indicate bioenergetic improvement to salmonids rearing in a flooded terrestrial floodplain because of the abundance of zooplankton (primary production), rather than having to rely on less dense prey items in the riverine channels, such as larval fish and benthic macroinvertebrates, and expending more energy for their capture. Therefore, construction of element IVc would be likely to result in bioenergetic improvement for all listed species.

EFFECTS RELATED TO THE 2017 EMERGENCY RESPONSE CONSTRUCTION PROJECT ACTIONS

Avoidance and minimization measures were implemented during the 2017 Emergency Response Construction Project. A worker environmental awareness program was provided to construction personnel prior to construction activities at element IVa, due to the proximity to potentially suitable riparian brush rabbit habitat. Construction personnel were notified of their responsibilities and provided with information on the life history of Federally listed species with the potential to occur in the construction footprint and vicinity. A biological monitor was onsite during all construction within element IVa. The biological monitor conducted preconstruction surveys for riparian brush rabbit, and was present to observe all construction activities within this area. See **Appendix H** for the construction monitoring report.

The implementation of the 2017 Emergency Response Construction Project did not result in adverse effects to special-status fish, because no waterside habitat was affected. The implementation of the 2017 Emergency Response Construction Project did not result in adverse effects to VELB, because no elderberry shrubs were located within 100 feet of project activities; however, some riparian habitat associated with elderberry shrubs was removed.

The implementation of the 2017 Emergency Response Construction Project resulted in the removal of 1.61 acres of potentially suitable habitat for riparian brush rabbit and associated with elderberry shrubs at element IIIb, IVa, Va, VIa.1, and VIbcde (see **Table 5**; see also **Appendix G**). No riparian brush rabbit was observed during the construction activities in this element, including during the removal of the vegetation. As described above under

“Valley Elderberry Longhorn Beetle” and “Riparian Brush Rabbit” within this section, proposed conservation measures (see the “Avoidance and Minimization Measures” section above) would minimize direct loss of riparian habitat in conjunction with compensation for adverse effects. The Phase 3 Repair Project would include restoration of at least 9.9 acres (and up to 11.1 acres) of riparian forest and riparian scrub habitats and upland refugia in the setback area at element IVc (**Exhibit 12**). Implementing such measures is anticipated to avoid a net reduction in the number of VELB, riparian brush rabbit, and their associated habitats.

CUMULATIVE EFFECTS

Cumulative effects include the effects of present, pending, and future State, tribal, local, or private actions that are reasonably certain to occur in the action area under consideration. The effects of projects that require a federal action are not considered in the cumulative effects evaluation during Section 7 consultation evaluation because they are subject to separate consultation (USFWS and NMFS 1998). For example, the Central Lathrop Specific Plan (Phase 1) addresses the development of 1,521 acres of land immediately east of the RD 17 levee elements IIIa and IIIb, south of Dos Reis and north of the housing development adjacent to element IVa. The USFWS issued a Biological Opinion for this project (USFWS File No. 1-1-06-F-0114), which analyzed the effects of the project on riparian brush rabbit and VELB. Therefore, this development is not considered cumulative to the proposed project. Also, the nonfederal action must be located in the action area, or project site, that is evaluated in the Section 7 consultation process (USFWS and NMFS 1998). Several present, pending, and future projects that are located in or near the action area under consideration in this consultation could result in effects similar to those of the proposed action.

SUMMARY OF PRESENT, PENDING, AND FUTURE PROJECTS IN THE PHASE 3 REPAIR PROJECT AREA

FLOOD DAMAGE REDUCTION SYSTEM IMPROVEMENTS

Two other proposed projects related to improvements to flood damage reduction systems are located near RD 17: the Lower San Joaquin River Feasibility Study, which would determine needed improvements for future flood protection systems in an effort to reach or exceed the future 200-year level of flood protection; and the Smith Canal Closure Structure, which would install a flood control gate in the Delta in Stockton, north of the Deep Water Ship Channel, to prevent flood flows from entering the Smith Canal in the event of an imminent or existing levee breach and during 100-year flood events.

These projects may affect federally listed species and require a federal action, and therefore would be subject to Section 7 consultation. Where adverse effects would occur on the landside of the levees, the project proponents may need incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Repair Project because they would undergo federal review and permitting as necessary—either through a Section 7 consultation or through SJMSCP compliance. This would ensure that adverse effects would be fully mitigated.

DEVELOPMENT PROJECTS

Development projects within the RD 17 boundaries include projects in the cities of Manteca, Stockton, and Lathrop, and in unincorporated areas of San Joaquin County. These projects have been described and analyzed in their respective environmental documents, including the following:

- River Islands Project;
- San Joaquin County General Plan 2010, adopted in 1992 and as amended;
- City of Stockton General Plan, adopted in 1990 and as amended through November 3, 1998;
- City of Lathrop General Plan, adopted in 1991 and as amended through January 2003;
- Central Lathrop Specific Plan, adopted in November 2004;

- West Lathrop Specific Plan, adopted in 1995;
- Manteca General Plan, adopted in 1988 and as amended through December 20, 1993;
- City of Lathrop Water, Wastewater, and Recycled Water Master Plan, adopted in 2001 and as amended through November 9, 2004;
- City of Manteca Wastewater Treatment Plant expansion; and
- 2001 Regional Transportation Plan, San Joaquin Council of Governments, 2001.

San Joaquin County covers approximately 909,000 acres, with approximately 809,000 acres (or nearly 90 percent of the county) used or available for agriculture (i.e., row and field crops, orchards, vineyards, and grazing lands). The remaining lands are dominated by various types of development (approximately 59,000 acres), natural habitats (e.g., woodlands, riparian), and open water (e.g., lakes, rivers, Delta waterways). Most county residents and development are located in incorporated cities (i.e., Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton, and Tracy). The SJMSCP anticipated that 147,000 acres of various categories of open space lands (including agriculture, range lands, and natural) in the county would be converted to non–open space uses between 2001 and 2051, based on full buildout of each of the general plans in the county and construction of all anticipated utility, transportation, and other public projects. In addition, approximately 59,000 acres of infill of urban lands were presumed to occur in this 50-year time frame.

Many development projects near the Phase 3 Repair Project area, including those described above, have been implemented recently or are in various stages of planning and entitlement, including the River Islands project. These current, pending, and potential future projects may affect federally listed species and require a federal action, and therefore would be subject to Section 7 consultation. Or, for those occurring within the SJMSCP permit area within San Joaquin County, the project applicants are expected to seek incidental take authorization, pursuant to incidental take permits used under the SJMSCP. Planning efforts in San Joaquin County have addressed the cumulative effects of development in the county, through preparation and adoption of the SJMSCP. The effects of these projects are not considered cumulative to the Phase 3 Repair Project because they would undergo federal review and permitting as necessary—either through Section 7 consultation or SJMSCP compliance.

ANALYSIS OF CUMULATIVE EFFECTS

GROWTH INDUCEMENT

Direct growth inducement would result if a project would include construction of new housing. Indirect growth inducement would occur, for instance, if implementing a project were to result in any of the following:

- substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises);
- substantial short-term employment opportunities (e.g., construction employment) that indirectly would stimulate the need for additional housing and services to support the new temporary employment demand; and/or
- removal of an obstacle to additional growth and development, such as removing a constraint on a required public utility or service (e.g., construction of a major sewer line with excess capacity through an undeveloped area).

Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density, or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Local land use decisions are within the jurisdiction of the cities and county in the Phase 3 Repair Project area: the City of Stockton, the City of Lathrop, the City of Manteca, and San Joaquin County. Each of these entities has adopted a General Plan consistent with State law. These General Plans provide an overall framework for growth and development within the jurisdiction of each agency, including the Phase 3 Repair Project area. Within the RD 17 boundaries, as elsewhere, population growth and urban development also are influenced by national, regional, and local economic conditions.

Because the Phase 3 Repair Project would not include construction of housing, it would not directly induce growth. Construction activities would generate short-term employment, but project-related construction jobs are expected to be filled from the existing local employment pool and not to indirectly induce growth or result in a population increase, nor would implementation of the project indirectly induce growth by creating permanent new jobs.

The Phase 3 Repair Project would accommodate growth currently approved or planned for undeveloped lands within the RD 17boundaries. These lands have been identified as the places most suitable for urban growth in the General Plans and additional planning policy documents of the cities of Lathrop, Manteca, and Stockton, and San Joaquin County. The Phase 3 Repair Project would allow development to proceed when economic and market conditions are favorable.

Development within the RD 17 boundaries is directed by the Central Lathrop Specific Plan and the West Lathrop Specific Plan in the City of Lathrop, the City of Stockton General Plan, the City of Manteca General Plan, and the San Joaquin County General Plan. The cities of Lathrop and Manteca are where the majority of planned or proposed development projects would be located. Environmental documents have been prepared to address the General Plans in these areas.

This information provides substantial evidence that the Phase 3 Repair Project would accommodate anticipated growth in a manner that would be consistent with adopted local growth management plans and with the State Plan of Flood Control. Thus, the Phase 3 Repair Project, despite accommodating buildout of adopted Specific Plans and General Plans in the cities of Lathrop, Manteca, and Stockton, would not be growth inducing itself.

CUMULATIVE EFFECTS ON LISTED SPECIES

Implementing the plans and projects described above would permanently disturb undeveloped land that currently is or has recently been in agricultural use. These projects would have cumulative effects on agricultural resources (by converting agricultural land to nonagricultural uses) and remnant native habitats (such as woodlands and marshes), which would have the potential to cause permanent adverse cumulative effects on the species, including federally listed species, for which these lands provide habitat.

Large areas of native riparian and wetland vegetation in the Phase 3 Repair Project area and Central Valley region have been lost or degraded over the past 150 years. USFWS estimates that more than 90 percent of wetland and riparian habitat has been lost in the Central Valley, compared to historic levels (USFWS 1989). Most losses have occurred because of CVP and SWP facility construction and alteration of flow patterns below dams, particularly channelization, and then clearing or filling behind levees for the conversion to agriculture and urban land uses. Alterations to the San Joaquin River channel have resulted over time in homogenous, trapezoidal channels with little instream structure; narrow and sparse bands of riparian vegetation that provide only limited SRA habitat functions; limited recruitment of large woody debris; and limited habitat conditions for native fish species and other aquatic organisms. This habitat conversion has affected many plant and wildlife species substantially, resulting in various species being listed as threatened or endangered under the ESA as well as under the California Endangered Species Act.

Present and future conversions of open space lands in San Joaquin County and the region consist primarily of converting agricultural lands to residential and urban development. Several flood risk management projects are

being implemented across the Central Valley, including San Joaquin County, to improve the integrity of levees. However, some of these flood risk management projects would implement compensatory mitigation in the form of habitat creation and preserves, designed to actually increase these habitats and their values related to ecosystem functions and special-status species. Upstream from the Phase 3 Repair Project area, the SJRRP would result in future structural and channel improvements to benefit special-status fish and wildlife species (Reclamation and DWR 2011). Nevertheless, even with these benefits, the overall losses of sensitive habitats in the Phase 3 Repair Project region, the numerous threatened and endangered species that are present, the ongoing declines of other species, and the continuing conversions of habitats and open space lands to various developments are evidence that past, present, and reasonably foreseeable future projects would combine to result in significant cumulative effects on biological resources.

Development projects (i.e., residential, commercial, industrial), infrastructure projects, and flood facilities improvement projects include or would include grading and other earthmoving activities that could result in temporary and short-term localized soil erosion that could affect hydrology and would have the potential to release materials (e.g., runoff of soils or contaminants) into the San Joaquin River. Potential increases in sedimentation, turbidity, and contaminants could expose and adversely affect fish and aquatic habitats. However, these site-specific effects are not expected to combine with the effects of other activities, because compliance with the NPDES regulations, including construction site BMPs, would help control erosion at each construction site. The effects from development projects, infrastructure projects, and flood facilities improvement projects would be temporary and short-term, and soil erosion would be localized.

CONCLUSIONS AND DETERMINATION

In conclusion, based on the biology and ecology of the federally listed species that have the potential to occur in the Phase 3 Repair Project area, the environmental baseline for the action area, and the effects of the proposed action and its cumulative effects, implementing the Phase 3 Repair Project may affect and is likely to adversely affect VELB and riparian brush rabbit, and would result in no adverse effect on delta smelt, Central Valley fall/late fall–run Chinook salmon, Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley steelhead, and green sturgeon. Designated critical habitat in the action area has been designated for delta smelt, Central Valley steelhead, and green sturgeon; however, none would be adversely modified or destroyed.

- **Valley elderberry longhorn beetle:** The Phase 3 Repair Project may affect and is likely to adversely affect VELB by transplanting eight elderberry shrubs. Although VELB habitat credits comparable to 367 elderberry seedlings and 367 associated native plantings would be purchased from a USFWS-approved VELB habitat conservation bank to compensate for effects on VELB and effects on 268 elderberry stems (greater than 1 inch in diameter at ground level), an adverse effect on the species could occur. Removal of shrubs in which larvae are present could result in larvae mortality if the health of the shrubs is adversely affected, and a temporary loss of habitat available to the beetle during the establishment of seedlings would occur.

- **Riparian brush rabbit:** The Phase 3 Repair Project, including the 2017 Emergency Response Construction Project, may affect and is likely to adversely affect riparian brush rabbit by removing 3.31 acres of landside riparian habitat that is suitable for the species, contributing to the further reduction of available habitat for this species.

  However, the Phase 3 Repair Project would include restoring approximately 9.9 acres (and up to 11.1 acres) of compensatory riparian habitat (**Exhibit 12**) to offset project-related habitat losses. After the new setback levee in element IVc is constructed and certified, a small section of the existing levee then would be partially degraded. Between 25 feet from the landside toe of the existing levee and 25 feet from the waterside toe of the new setback levee are approximately 4 acres of ruderal grassland that could be restored as riparian scrub habitat and approximately 2 additional acres of riparian scrub habitat will be restored and/or enhanced between the waterside toe of the existing levee and the river (**Exhibit 12**). The restored riparian habitat would consist of willows, cottonwoods, valley oaks, wild rose, California blackberry, and grasses, which is comparable to the composition of habitats where this species is documented to occur along the RD 17 levees. Apart from a small notch along the north side, the existing levee would remain in place, and up to 5 acres of Great Valley oak woodland would be established along either side of it, thus providing upland refugia for the species during high-water events. The restored habitat in the setback levee area would be contiguous with existing waterside riparian habitat along element IVc; this waterside riparian habitat along element IVc extends northward through elements IVa, IIIa, and IIIb, and southward through elements Va and VIa.1. Documented occurrences exist of riparian brush rabbit in the waterside riparian habitat in elements IIIa and IIIb, north of element IIIa and south of element VIa.1; therefore, reestablishing and protecting riparian habitat in element IVc would provide expanded and connected habitat for this species.

  RD 17 also is evaluating options for providing off-site compensatory habitat to offset Phase 3 Repair Project effects on riparian brush rabbit. Additional off-site compensatory habitats would include preserving existing waterside riparian habitats and/or restoring natural riparian habitats. These options would be evaluated in coordination with USFWS during the Section 7 consultation.

- **Federally listed fish species:** The Phase 3 Repair Project would result in no adverse effects on federally proposed and federally listed fish species considered in this BA. Effects are not expected to occur because of the avoidance and minimization measures to be implemented by the Phase 3 Repair Project. The Phase 3 Repair Project would include several measures that would avoid potential direct environmental effects during project construction. The potential effects of increased sedimentation or turbidity, and/or release of contaminants on fish and other aquatic organisms, would be avoided and minimized through the use of BMPs (e.g., source control, detention basins, revegetation, and spill containment plan) that would maintain surface water quality conditions in receiving waters and minimize disturbance to fish and other aquatic habitats. Construction-related lighting and vibration could disrupt fish behaviors and/or increase predation risk, the implementation of the lighting and vibration measures would avoid direct and indirect take of fish during construction. No waterside riparian or SRA habitat would be removed.

ESSENTIAL FISH HABITAT ASSESSMENT

The Magnuson-Stevens Fishery Conservation and Management Act, as amended (16 USC 1801), requires that EFH be identified and described in federal fishery management plans. Federal agencies must consult with NMFS on any activity that they fund, permit, or carry out that may adversely affect EFH. The EFH regulations require that federal agencies obligated to consult on EFH also provide NMFS with a written assessment of the effects of any action on EFH (50 CFR 600.920). NMFS is required to provide EFH conservation and enhancement recommendations to federal agencies. The statute also requires federal agencies receiving NMFS EFH conservation recommendations to provide a detailed written response to NMFS within 30 days of receipt, detailing how they intend to avoid, mitigate, or offset the impact of activity on EFH (Section 305[b][4][B]).

EFH is defined as those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity. For the purposes of interpreting the definition of EFH, "waters" includes aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include areas historically used by fish where appropriate; "substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities; "necessary" means habitat required to support a sustainable fishery and a healthy ecosystem; and "spawning, breeding, feeding, or growth to maturity" covers all habitat types used by a species throughout its life cycle.

The Pacific Fishery Management Council has identified and described EFH, adverse impacts, and recommended conservation measures for salmon in Amendment 14 to the Pacific Coast Salmon Fishery Management Plan (PFMC 2003). Amendment 18 to the Pacific Coast Salmon Fishery Management Plan revises the description and identification of EFH for Pacific salmon, designates habitat areas of particular concern, modifies the current information on fishing activities and potential measures to minimize their effects on EFH, and updates the list of fishing and non-fishing related activities that may adversely affect EFH and potential conservation and enhancement measures to minimize those effects (NMFS 2014c). Freshwater EFH for Pacific salmon in the Central Valley (i.e., Chinook salmon) includes waters currently or historically accessible to salmon within the Central Valley ecosystem, as described in Myers et al. (1998), and includes the segment of the San Joaquin River in the action area. EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia from high flows during floods as salmon migrate along the mainstem in this area. Although evidence of current or historical Chinook salmon distribution is lacking for the western tributaries (Yoshiyama et al. 2001), the lower reaches of these tributaries could provide juvenile rearing habitat or refugia. Central Valley fall/late fall–run Chinook salmon is a species managed under the Pacific Coast Salmon Plan that occurs in the San Joaquin River.

THE PROPOSED ACTION

The proposed action is described in detail in the "Description of the Proposed Action" section of this BA.

ESSENTIAL FISH HABITAT DESIGNATION IN THE ACTION AREA

EFH has been identified for Chinook salmon, which includes Central Valley fall/late fall-run Chinook salmon. The species account for this species is provided below; the species accounts for federally-listed Chinook salmon are included in the "Species Accounts" section of this BA. The action area and environmental baseline, respectively, are described in the "Action Area" and "Environmental Baseline" sections of this BA.

Central Valley Fall/Late Fall-run Chinook Salmon Evolutionarily Significant Unit

On September 16, 1999 (64 FR 50393), NMFS determined that listing was not warranted for the Central Valley fall/late fall–run Chinook salmon ESU; however, the ESU was designated as a future candidate for listing because of concerns about specific risk factors. On April 14, 2004 (69 FR 19975), the ESU was reclassified as a species of concern. The ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin River basins and their tributaries, east of the Carquinez Strait. The Central Valley fall/late fall–run Chinook salmon ESU currently is the only run of Chinook salmon in the San Joaquin River system.

Adult Central Valley fall/late fall–run Chinook salmon enter the Sacramento and San Joaquin river systems from September through January and spawn from October through February. In general, San Joaquin River populations tend to mature at an earlier age and spawn later in the year than Sacramento River populations (Baker and Morhardt 2001). These differences may be phenotypic responses to the generally warmer temperature and lower flow conditions found in the San Joaquin River basin, relative to the Sacramento River basin.

Juveniles typically rear in freshwater for 3 to 6 months (fall-run) and up to 12 months (late fall–run) before entering the ocean. Juveniles migrate downstream from January through June. Juvenile Chinook salmon prefer water depths of 0.5 foot to 3.3 feet and velocities of 0.26 foot to 1.64 feet per second (Raleigh et al. 1986). Important winter habitat for juvenile Chinook salmon includes flooded bars, side channels, and overbank areas with relatively low water velocities. Juvenile Chinook salmon have been found to rear successfully in floodplain habitat, which routinely floods but is dry at other times. Growth rates appear to be enhanced by the conditions found in floodplain habitat (Sommer et al. 2001).

Cover structures, space, and food are necessary components for Chinook salmon rearing habitat. Suitable habitat includes areas with instream and overhead cover in the form of undercut banks, downed trees, and large, overhanging tree branches. The organic materials forming fish cover also help provide sources of food, in the form of both aquatic and terrestrial insects.

Fall-run Chinook salmon adults primarily pass through the Phase 3 Repair Project area on their way to spawn in upstream tributaries of the San Joaquin River (Moyle 2002). Juvenile fall-run Chinook salmon emigrate from San Joaquin River tributaries (e.g., the Stanislaus, Merced, and Tuolumne rivers) and other river tributaries through the San Joaquin River during the late winter and spring (February through mid-June) (San Joaquin River Group Authority 2009). Juvenile Chinook salmon use the edges of rivers and sloughs for rearing as they emigrate downstream (Moyle 2002).

Critical Habitat

No critical habitat has been designated for Central Valley fall/late fall-run Chinook salmon.

Essential Fish Habitat

EFH has been designated for Pacific Salmon. This includes identification of Chinook salmon EFH, which occurs in the project and action areas. Central Valley fall/late fall-run Chinook salmon ESU is in the Phase 3 Repair Project area along the San Joaquin River. EFH includes migration, holding, and rearing habitat and opportunistic/intermittent spawning, holding, and rearing habitat for the San Joaquin River (NMFS 2014a). EFH for Chinook salmon in the Lower San Joaquin River includes the San Joaquin River, its eastern tributaries, and the lower reaches of the western tributaries that could provide juvenile rearing habitat or refugia during floods as salmon migrate along the mainstem in this area (NMFS 2014c).

Construction of element IVc would improve EFH, by providing the type of refuge habitat for juvenile salmonids during high-water flows as described in Amendment 18 for the lower San Joaquin River tributaries (NMFS 2014c).

RECOVERY PLAN FOR CENTRAL VALLEY FALL/LATE FALL–RUN CHINOOK SALMON EVOLUTIONARILY SIGNIFICANT UNIT

Although the Central Valley fall/late fall-run Chinook salmon is not listed as threatened or endangered under the ESA, the Sacramento–San Joaquin Delta Native Fishes Recovery Plan outlines conservation measures and restoration objectives and criteria for the species, including the San Joaquin River run, which CDFW recognizes as a distinct stock (USFWS 1996b). Reasons for decline identified by the plan include habitat loss, suitability of habitat, survival of outmigrants, harvest, hatcheries, and water quality. Conservation measures include:

- testing an electrical fish barrier and a physical barrier upstream from the confluence of the Merced River to prevent adult fish from straying,
- constructing and rehabilitating spawning riffles,
- constructing a temporary barrier at Old River to prevent entrainment of outmigrating smolts, and when possible,
- coordinating water releases to provide attraction or outmigration flows.

These efforts have been funded by a wide range of federal, State, and private agencies (USFWS 1996b).

EFFECTS OF THE PROPOSED ACTION

Effects of the proposed action are described below and in the “Direct and Indirect Effects on Species in the Action Area” and “Cumulative Effects” sections of this BA. The direct and indirect effects on Central Valley fall/late fall-run Chinook salmon would be similar to the effects described for Central Valley steelhead.

Available literature indicates that limited Chinook salmon spawning typically occurs well upstream from the Phase 3 Repair Project area. EFH in the San Joaquin River in the vicinity of the Phase 3 Repair Project area consists of adult and juvenile (smolt) Chinook salmon passage between upstream spawning grounds and the Pacific Ocean, and limited in-channel rearing habitat for juveniles (limited because it is situated in a reach of the San Joaquin River that is bound on both banks by levees, resulting in channel incision, and is disconnected from its currently non-functioning floodplain). The river extends onto its floodplain only during high-water events, and if fish are swept into the floodplain during high flow conditions, they likely would become stranded because of the absence of a secondary channel for returning flood flows to the river. The Phase 3 Repair Project would result in improvement of EFH as functioning floodplain-rearing habitat and improvement to existing EFH in the San Joaquin River channel, by reducing and reversing the effects of current channel incision in the immediate vicinity of element IVc. Furthermore, approximately 2 acres of SRA habitat would be created and/or enhanced through revegetation actions between the river and the waterside toe of the existing levee in element IVc (see **Appendix E**).

Levee degradation and floodplain grading activities in element IVc would restore connectivity to the historic floodplain and improve habitat conditions in the floodplain. Although both actions would be constructed in dry conditions (above HTL), a potential short-term indirect effect of construction may be a temporary increase in sediment in the San Joaquin River, especially during the first storm or flooding event after construction. The measures (erosion control and revegetation) described in the “Avoidance and Minimization Measures” section of this BA are designed to reduce or capture any mobilized sediment resulting from the year’s first rain or flooding event. Therefore, any construction-related sediment load would be temporary and negligible, especially when compared to the existing sediment load of the San Joaquin River and the project would not result in adverse effects on EFH.

The project would increase the amount and improve the quality of EFH in the project area. The new setback levee with floodplain in element IVc would improve EFH by providing refuge habitat for juvenile salmonids during high-water events, as described in Amendment 18 (NMFS 2014c). The newly reconnected floodplain would provide habitat for juvenile Chinook salmon rearing. It would also alter the channel dynamics in the immediate vicinity such that the channel incision process is expected to be reversed, thereby improving juvenile and adult migratory passage habitat.

PROPOSED CONSERVATION MEASURES

Proposed conservation measures are presented in the "Description of the Proposed Action" and "Direct and Indirect Effects on Species in the Action Area" sections of this BA. The measures include avoidance and minimization measures.

CONCLUSIONS

The proposed action would not affect the spawning, rearing, or migratory EFH functions of Chinook salmon currently or previously managed under the Magnuson-Stevens Fishery Conservation and Management Act in the San Joaquin River.

17. Letter from USACE to USFWS, requesting initiation of formal consultation. August 21, 2018.

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS, SACRAMENTO DISTRICT
1325 J STREET
SACRAMENTO, CALIFORNIA 95814-2922

Environmental Resources Branch

Ms. Jennifer Norris, Field Supervisor
U.S. Fish & Wildlife Service
2800 Cottage Way, Suite W-2605
Sacramento, California 95825-1846

Dear Ms. Norris:

I am writing to request formal consultation under Section 7 of the Endangered Species Act, for a combined Section 404 and Section 10 Department of Army permit application and a Section 408 permission request for Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair Project (U.S. Fish and Wildlife Service [USFWS] File No. 08FBDT00-2015-TA-0303). The project is proposed by RD 17, and is located along the San Joaquin River in RD 17 in San Joaquin County, California. A copy of the May 2018, Final Biological Assessment (BA) for the Phase 3 – RD 17 Levee Seepage Repair Project, Including 2017 Emergency Response Construction, prepared by GEI Consultants, Inc., is enclosed.

Based on the available information, we have determined that, even with the avoidance and minimization measures included in the project description, the proposed action may affect, and is likely to adversely affect, federally listed valley elderberry longhorn beetle (*Desmocerus californicus*) (VELB) and riparian brush rabbit (*Syvilagus bachmani riparius*). We have concluded that the net overall effect of the proposed action on delta smelt (Hypomesus transpacificus) would likely be beneficial; however, we are requesting your concurrence with our determination that the proposed action may affect, but is not likely to adversely affect delta smelt and would not adversely modify or destroy designated critical habitat for delta smelt. If you disagree with this determination, please consider this letter as our request to formally consult on this species. If new information becomes available indicating that other listed species or critical habitat may be affected, we will follow the procedures under 50 CFR 402.16, Reinitiation of Consultation.

The Sacramento District (Corps) originally requested formal consultation in a letter, dated February 27, 2015. USFWS responded in a letter, dated October 2, 2015, and requested additional information (see Appendix D-5 of the enclosed BA). In a letter, dated March 8, 2017, we transmitted a revised BA together with specific responses to each element of the information request (BA Appendix D-6 of the assessment (BA). On March 22, 2017, we notified USFWS that emergency construction would occur as a result of the volume and duration of flood waters in the system. USFWS recommended avoidance and minimization measures followed by consultation following the emergency. The BA transmitted with our current initiation request includes the construction completed as an emergency action as well as remaining portions of the Phase 3 Levee Seepage Repair Project.

The enclosed BA provides an updated description of the proposed action and clarifies which project features were constructed as emergency actions in response to the 2017 floods. Table 2 of the BA shows a comparison of all major RD 17 Phase 3 Levee Seepage Repair Project actions, those completed as emergency actions, and those features remaining to be constructed. The Phase 3 features that have not yet been constructed are the focus of this consultation.

To implement the Phase 3 Project, RD 17, through the Central Valley Flood Protection Board, is requesting permission from the U.S. Army Corps of Engineers pursuant to Section 14 of the Rivers and Harbors Act of 1899 (title 33 of the United States Code [USC], Section 408 [33 USC 408], referred to as Section 408, for alterations of Federal projects. RD 17 is also seeking a permit under Section 404 of the Clean Water Act (33 USC 1344) and Section 10 of the Rivers and Harbor Act (33 USC 403) for placement of fill into jurisdictional waters of the United States.

The following information is provided to your office to initiate consultation:

A description of the action to be considered: The proposed levee modifications would occur along 5.2 miles (27,456 feet) of the RD 17 levee system and would involve constructing: 17,020 feet of cutoff walls; 940 feet of seepage berms; 7,560 feet of chimney drains; 1,100 feet of new setback levee; and, placing fill on the landside slope of the levees wherever needed to achieve engineering design standards. The proposed action would also include: grading 8 acres of offset area (area between the existing levee and a new setback levee); restoring 9.9 to 11.5 acres of native vegetation in the offset area; degrading 400 feet of existing levee; raising a Pacific Gas and Electric Company (PG&E) high voltage tower footing; and, replacing a wooden railroad trestle bridge with a new embankment. Table 2 of the enclosed BA describes this information in greater detail by project element (i.e., reach). The proposed action would eliminate or reduce levee deficiencies, including through- and under-seepage, slope stability, erosion, and encroachments within the construction footprint.

Details of RD 17's preferred alternative are provided in the enclosed BA and accompanying CD. The CD contains the 65 percent engineering designs for the preferred alternative. RD 17 proposes to construct the project over two construction seasons.

A description of the specific area that may be affected by the action: The work proposed as part of the Phase 3 Project would involve modifying approximately 5.2 miles of the Federal levee on the east bank of the San Joaquin River to reduce the potential for flooding, flood damage, and public risk in RD 17. Appendix A, Exhibit 2 of the enclosed BA shows the location of the proposed Phase 3 work, including levee work completed as part of the Phase 3 emergency actions, and the earlier Phase 1 and Phase 2 projects. Site specific details are shown in the enclosed BA in Exhibits 4a through 4c, and 13a through 13c.

A description of any listed species or critical habitat that may be affected by the action: Federally listed VELB, riparian brush rabbit, and delta smelt may be affected by the proposed action. The proposed action occurs within designated critical habitat for delta smelt.

A description of the manner in which the action may affect any listed species or critical habitat and analysis of any cumulative impacts: We have determined that the proposed action may affect, and is likely to adversely affect, VELB and riparian brush rabbit. We have determined that the proposed action may affect, but not likely to adversely affect delta smelt.

VELB: The proposed action includes removing nine elderberry (*Sambucus spp.*) shrubs (host plant for VELB) from the construction area (see Exhibit 14 of the enclosed BA). These shrubs have a total of 268 stems greater than 1 inch in diameter. No VELB exit holes were visible on any of the stems. An additional nine shrubs would be protected with fencing. The proposed action would also remove about 3.31 acres of riparian habitat (i.e., Great Valley cottonwood riparian forest and Great Valley oak riparian forest) associated with elderberry shrubs. Removal of this habitat could adversely affect the VELB meta-population in this area by increasing the distance between occupied and unoccupied patches of habitat, and decreasing the likelihood of successful colonization of unoccupied habitat as a result of habitat fragmentation.

The effects on VELB resulting from removal of the potential host plants would be mitigated at the time of construction by transplanting the eight elderberry shrubs with stems greater than 1 inch in diameter at ground level. The eight elderberry shrubs that cannot be avoided would be transplanted to the offset area (i.e., water-ward of the new setback levee). In, addition, at least 9.9 acres of riparian forest and riparian scrub habitat would be established in the offset area. Because of the potential direct effects, including removal and transplantation of elderberry shrubs, we have determined that the proposed action may affect, and is likely to adversely affect VELB.

Riparian Brush Rabbit: Habitat suitable for riparian brush rabbit occurs in the project area and would be affected by the proposed project. The proposed action would remove 3.31 acres of landside riparian habitat—specifically Great Valley cottonwood riparian forest and Great Valley oak riparian forest--that is suitable for riparian brush rabbit (see Exhibit 15 of the enclosed BA). The project would also restore at least 9,9 acres of riparian forest and scrub-shrub habitat in the offset area. Avoidance and minimization measures are identified in the enclosed BA. Because of the removal of 3.31 acres of riparian brush rabbit habitat, we have determined that the proposed action may affect, and is likely to adversely affect, riparian brush rabbit.

Delta Smelt: Although the Phase 3 Levee Seepage Repair Project area is near the upper limit of the known distribution of delta smelt, it is included in the area designated as critical habitat for the species. A setback levee would be constructed along one reach and the existing project levee would be partially degraded to allow high water to flow onto the floodplain between the existing levee and the new setback levee. Fish and other aquatic organisms would also likely flow onto the floodplain. The offset area would be contoured to drain back into the San Joaquin River as the water recedes in a manner that would avoid trapping fish landward of the existing levee. Nevertheless, some stranding could occur and some predation could occur. Beneficial effects would also result from reconnecting a portion of the floodplain to the San Joaquin River. This is described in greater detail in the enclosed BA. The proposed action could result in some natural floodplain processes that could affect delta smelt should individuals enter flood plain (i.e., predation and/or stranding). With implementation of the avoidance and minimization measures identified in the BA, we have determined that the proposed action may affect, but is not likely to adversely affect delta smelt.

<u>Relevant reports including any environmental impact statement, environmental assessment, or biological assessment prepared</u>: A copy of the May 2018, "Final Biological Assessment, Phase 3 – RD 17 Levee Seepage Repair Project, Including 2017 Emergency Response Construction," prepared by GEI Consultants, Inc., is enclosed.

<u>Any other relevant available information on the action, the listed species, or critical habitat</u>: See the enclosed BA.

This constitutes the best scientific and commercial data available. If you need additional information, or determine that conditioning the permit and letter of permission or modifying the project would preclude the need for formal consultation, please contact us immediately.

A copy of this letter, with the enclosure, will be furnished to Dr. Steve Schoenberg, U.S. Fish and Wildlife Service, 2800 Cottage Way, Suite W-2605, Sacramento, CA 95825-1846. Copies of the letter will also be furnished: to Mr. Jeffrey Stuart, National Marine Fisheries Service, 650 Capitol Mall, Suite 5-100, Sacramento, CA 95814-4706; Mr. Dante Nomellini, c/o Nomellini, Grilli & McDaniel, P.O. Box 1416, Stockton, CA 95201; Mr. Henry Long, President, Reclamation District No. 17, P.O. Box 1461, Stockton, CA 95201; and Dr. Andrea Shephard, GEI Consultants, Inc., 2868 Prospect Park Drive, Suite 400, Rancho Cordova, CA 95670.

If you have any questions, please contact Ms. Tanis Toland, Environmental Manager, at (916) 557-6717 or by email at <u>Tanis.J.Toland@usace.army.mil</u>.

Sincerely,

Mark T. Ziminske

Mark T. Ziminske
Chief, Environmental Resources Branch

Enclosure

18. Letter from USACE to NMFS, requesting initiation of formal consultation. August 21, 2018.

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS, SACRAMENTO DISTRICT
1325 J STREET
SACRAMENTO, CALIFORNIA 95814-2922

Environmental Resources Branch

Ms. Maria Rae, Assistant Regional Administrator
National Marine Fisheries Service
650 Capitol Mall, Suite 5-100
Sacramento, California 95814-4700

Dear Ms. Rae:

I am writing to initiate informal consultation under Section 7 of the Endangered Species Act, for a combined Section 404 and Section 10 Department of Army permit application and a Section 408 permission request for Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair Project. We are also requesting to consult with your agency under the Magnusson-Stevens Fishery Conservation and Management Act (MSA) for Pacific Coast Salmon (*Oncorhynchus* spp.) essential fish habitat (EFH). The project is proposed by RD 17, and is located along the San Joaquin River in RD 17 in San Joaquin County, California. A copy of the May 2018, "Phase 3 – RD 17 Levee Seepage Repair Project, Including 2017 Emergency Response Construction, Final Biological Assessment" (BA), prepared by GEI Consultants, Inc., is enclosed.

Based upon the available information, we have determined that the overall effect of the proposed action on federally listed fish would be beneficial; however, we are requesting your concurrence with our determination that the proposed action may affect, but is not likely to adversely affect, federally listed Southern Distinct Population Segment (DPS) of North American green sturgeon (*Acipenser medirostris*), Central Valley steelhead DPS (*Oncorhynchus mykiss*), Central Valley spring-run Chinook salmon evolutionarily significant unit (ESU) (*Oncorhynchus tshawytscha*), and the Sacramento River winter-run Chinook salmon ESU (*Oncorhynchus tshawytscha*). The proposed action will not result in destruction or adverse modification of designated critical habitat for any of these species and will not adversely affect Chinook salmon EFH. We request your written concurrence with our determinations. If you disagree with this determination, please consider this letter as our request to formally consult on these species. If new information becomes available indicating that other listed species or critical habitat may be affected, we will follow the procedures under 50 CFR 402.16, Reinitiation of Consultation.

The Sacramento District (Corps) originally requested to informally consult on the RD 17 Levee Seepage Repair Project Phase 3 in a letter dated March, 27, 2015. The National Marine Fisheries Service (NMFS) responded in a letter, dated July 7, 2015, and requested additional information (see Appendix D-3 of the enclosed BA). In a letter, dated March 8, 2017, the Corps transmitted a revised BA, which included specific responses to each element of the information request (see Appendix D-4 of the enclosed BA). This information was also incorporated into the main body of the BA, as appropriate. On March 22, 2017, the Corps advised NMFS of anticipated emergency construction in RD 17. On April 6, 2017, the Corps authorized RD 17 to discharge fill into waters of the United States for the 2017 Emergency Response Construction Project (SPK-2009-001466) under Regional General Permit No. 8 (Emergency Actions). Informal consultation with NMFS regarding the Phase 3 Levee Seepage Repair Project continued through March 2018. In a letter dated May 16, 2018, NMFS advised the Corps of consultation close out due to inactivity.

The enclosed BA provides an updated description of the proposed action and clarifies which project features were constructed as emergency actions in response to the 2017 floods. Table 2 of the BA shows a comparison of all major RD 17 Phase 3 Levee Seepage Repair Project actions, those completed as emergency actions, and those features remaining to be constructed. The Phase 3 features that have not yet been constructed are the focus of this consultation.

To implement the Phase 3 Levee Seepage Repair Project, RD 17, through the Central Valley Flood Protection Board, is requesting permission from the U.S. Army Corps of Engineers pursuant to Section 14 of the Rivers and Harbors Act of 1899 (title 33 of the United States Code [USC], Section 408 [33 USC 408], referred to as Section 408, for alterations of Federal projects. RD 17 is also seeking a permit under Section 404 of the Clean Water Act (33 USC 1344) and Section 10 of the Rivers and Harbor Act (33 USC 403) for placement of fill into jurisdictional waters of the United States.

The following information is provided to your office to initiate consultation:

A description of the action to be considered: The proposed levee modifications would occur along 5.2 miles (27,456 feet) of the RD 17 levee system and would involve constructing: 17,020 feet of cutoff walls; 940 feet of seepage berms; 7,560 feet of chimney drains; 1,100 feet of new setback levee; and, placing fill on the landside slope of the levees wherever needed to achieve engineering design standards. The proposed action would also include: grading 8 acres of offset area (area between the existing levee and a new setback levee); restoring 9.9 to 11.5 acres of native vegetation in the offset area; degrading 400 feet of existing levee; raising a Pacific Gas and Electric Company (PG&E) high voltage tower footing; and, replacing a wooden railroad trestle bridge with a new embankment. Table 2 of the enclosed BA describes this information in greater detail by project element (i.e., reach). The proposed action would eliminate or reduce levee deficiencies, including through- and under-seepage, slope stability, erosion, and encroachments within the construction footprint.

Details of RD 17's preferred alternative are provided in the enclosed BA and accompanying CD. The CD contains the 65 percent engineering designs for the preferred alternative. RD 17 proposes to construct the project over two construction seasons.

A description of the specific area that may be affected by the action: The work proposed as part of the Phase 3 Levee Repair Project would involve modifying approximately 5.2 miles of the Federal levee on the east bank of the San Joaquin River to reduce the potential for flooding, flood damage, and public risk in RD 17. Appendix A, Exhibit 2 of the enclosed BA shows the location of the proposed Phase 3 work, including levee work completed as part of the Phase 3 emergency actions, and the earlier Phase 1 and Phase 2 projects. Site specific details are shown in the enclosed BA in Exhibits 4a through 4c, and 13a through 13c.

A description of any listed species or critical habitat that may be affected by the action: We have determined that the proposed action may affect, but is not likely to adversely affect, Southern DPS of North American green sturgeon, Central Valley steelhead DPS, Central Valley spring-run Chinook salmon ESU, and the Sacramento River winter-run Chinook Salmon ESU.

A description of the manner in which the action may affect any listed species or critical habitat and analysis of any cumulative impacts: The Phase 3 Levee Seepage Repair Project would involve constructing cutoff walls, which would entail degrading the top one-third to one-half of the levee. The levee degrade would begin at the waterside edge of the levee crown and would be accomplished without disturbing the waterside levee face. Construction of some cutoff walls, specifically those in Elements Va and VIa.1 would occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance. Artificial lights used during nighttime construction would be shielded and directed away from the waterside levees.

Implementing cutoff walls as part of the Phase 3 Levee Seepage Repair Project would disturb soils along the top of the levee which, through wind and water erosion, could enter the San Joaquin River. Soil disturbed during construction of seepage berms and other features on the landside of the levee could enter drainage ditches and ultimately be pumped into the San Joaquin River. Therefore, erosion could temporarily increase turbidity and sedimentation in nearby waterways if soils are transported in river flows or stormwater runoff. Water quality best management practices, including a Stormwater Pollution Prevention Plan, would be implemented to avoid and minimize adverse effects. These measures are identified in the BA.

Vibratory compaction equipment would be specifically restricted on the RD 17 levees, and the limited amount of compaction that would occur on landside chimney drain locations (specifically Elements Ia and VIIg) would be restricted to normal work day hours, outside of sunrise and sunset hours in order to avoid peak foraging and migration timing.

Riprap would be placed around trees above the high tide line (HTL). Placement of riprap can affect the growth and health of the trees and affect, hydraulics, especially if the rock were to move down below the HTL.

A setback levee would be constructed along one reach and the existing project levee would be partially degraded to allow high water to flow onto the floodplain between the existing levee and the new setback levee. Fish and other aquatic organisms would also likely flow onto the floodplain. The offset area would be contoured to drain back into the San Joaquin River as the water recedes in a manner that would avoid trapping fish landward of the existing levee. Nevertheless, some stranding could occur and some predation could occur. Beneficial effects would also result from reconnecting a portion of the floodplain to the San Joaquin River. This is described in greater detail in the enclosed BA.

Relevant reports including any environmental impact statement, environmental assessment, or biological assessment prepared: A copy of the May 2018, "Final Biological Assessment, Phase 3 – RD 17 Levee Seepage Repair Project, Including 2017 Emergency Response Construction," prepared by GEI, is enclosed.

Any other relevant available information on the action, the listed species, or critical habitat: See the enclosed BA.

This constitutes the best scientific and commercial data available. If you need additional information, or determine that conditioning the permit and letter of permission or modifying the project would preclude the need for formal consultation, please contact us immediately.

A copy of this letter, with the enclosure, will be furnished to Mr. Howard Brown, National Marine Fisheries Service, 650 Capitol Mall, Suite 5-100, Sacramento, California 95814-4700. Copies of the letter will also be furnished: to Dr. Steve Schoenberg, U.S. Fish and Wildlife Service, 2800 Cottage Way, Suite W-2605, Sacramento, CA 95825-1846; Mr. Dante Nomellini, c/o Nomellini, Grilli & McDaniel, P.O. Box 1416, Stockton, CA 95201; Mr. Henry Long, President, Reclamation District No. 17, P.O. Box 1461, Stockton, CA 95201; and Dr. Andrea Shephard, GEI Consultants, Inc., 2868 Prospect Park Drive, Suite 400, Rancho Cordova, CA 95670.

If you have any questions, please contact Ms. Tanis Toland, Environmental Manager, at (916) 557-6717 or by email at Tanis.J.Toland@usace.army.mil.

Re: Endangered Species Act Section 7(a)(2) Biological Opinion, and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Response for the Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair Project along the San Joaquin River

Dear Mr. Ziminske:

Thank you for your letter of August 21, 2018, requesting initiation of consultation with the National Marine Fisheries Service (NMFS) pursuant to section 7 of the Endangered Species Act of 1973 (ESA) (16 U.S.C. 1531 et seq.) for the Phase 3 of the RD 17 Levee Seepage Repair Project (Project). The Project will implement repairs to multiple levee sites along the San Joaquin River in the southern Delta within San Joaquin County, California.

Thank you, also, for your request for consultation pursuant to the essential fish habitat (EFH) provisions in Section 305(b) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA)(16 U.S.C. 1855(b)) for this action.

The enclosed biological opinion, based on the biological assessment, and best available scientific and commercial information, concludes that the project is not likely to jeopardize the continued existence of the federally listed threatened Central Valley spring-run Chinook salmon (*Oncorhynchus tshawytscha*) Evolutionarily Significant Unit, the threatened California Central Valley (CCV) steelhead (*O. mykiss*) Distinct Population Segment (DPS), and the threatened Southern DPS (sDPS) of the North American green sturgeon (*Acipenser medirostris*). NMFS has also concluded that the Project is not likely to destroy or adversely modify the designated critical habitats for CCV steelhead, and sDPS green sturgeon that occur within the action area. NMFS has included an incidental take statement with reasonable and prudent measures and non-discretionary terms and conditions that are necessary and appropriate to avoid, minimize, or monitor incidental take of listed species associated with the Project.

This letter also transmits NMFS' EFH conservation recommendations for Pacific salmon as required by the MSA as amended (16 U.S.C. 1801 *et seq.*).

The EFH consultation concludes that the proposed action would adversely affect the EFH of Pacific salmon in the action area. The EFH consultation adopts the ESA reasonable and prudent measures and associated terms and conditions from the biological opinion and includes additional conservation recommendations specific to the adverse effects to Pacific salmon EFH in the action area as described in Amendment 18 of the Pacific Coast Salmon Plan.

The U.S. Army Corps of Engineers (USACE) has a statutory requirement under section 305(b)(4)(B) of the MSA to submit a detailed written response to NMFS within 30 days of receipt of these conservation recommendations, and 10 days in advance of any action, that includes a description of measures adopted by the USACE for avoiding, minimizing, or mitigating the impact of the Project on EFH (50 CFR 600.920(j)). If unable to complete a final response within 30 days, the USACE should provide an interim written response within 30 days before submitting its final response. In the case of a response that is inconsistent with our recommendations, the USACE must explain its reasons for not following the recommendations, including the scientific justification for any disagreements with NMFS over the anticipated effects of the Phase 3 of the RD 17 Levee Seepage Repair Project and the measures needed to avoid, minimize, or mitigate such effects.

Please contact Jeffrey Stuart in NMFS' West Coast Region, California Central Valley Office at (916) 930-3607 or via email at J.Stuart@noaa.gov if you have any questions concerning this section 7 consultation, or if you require additional information.

Sincerely,

Maria Rea

1. INTRODUCTION

This Introduction section provides information relevant to the other sections of this document and is incorporated by reference into Sections 2 and 3 below.

1.1 Background

The National Marine Fisheries Service (NMFS) prepared the biological opinion (opinion) and incidental take statement (ITS) portions of this document in accordance with section 7(b) of the Endangered Species Act (ESA) of 1973 (16 United States Code [USC] 1531 et seq.), and implementing regulations at 50 Code of Federal Regulations (CFR) 402.

We also completed an essential fish habitat (EFH) consultation on the proposed action, in accordance with section 305(b)(2) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA) (16 USC 1801 et seq.) and implementing regulations at 50 CFR 600.

The following provides some background information regarding the need for the levee seepage repair project in Reclamation District 17 (RD 17):

The RD 17 levee system functions to reduce the risk of damage from floods and was initially designed to facilitate agricultural development on the extensive San Joaquin Valley floodplains and to support navigation on the San Joaquin River. Narrow levee alignments along the rivers were designed to contain flows generated by common floods, and bypasses were constructed to carry overflows generated by large floods. The close-set levees ensured that water velocities would help scour the river bottom and move sediment through the river system, reducing dredging costs for sustaining navigation. Starting in approximately 1863, RD 17 undertook the maintenance and reconstruction of the levee system.

Some of the levees in the Delta are considered “federal project levees.” These levees were constructed or reconstructed (e.g., existing or damaged farm levees were improved during repairs) by the United States Army Corps of Engineers (USACE) and are intended to meet federal standards. Construction of the federal levee system that encompasses the current RD 17 levees along Walthall Slough, the San Joaquin River, and French Camp Slough began in 1944 and was completed in 1963. The levee system has since been substantially upgraded to meet Federal Emergency Management Agency (FEMA) requirements for flood protection during a 100-year flood event (flood with a 1 percent chance of occurring in any given year, or 0.01 annual exceedance probability [AEP]). In 1990, after extensive analysis, the RD 17 levees were accredited by FEMA as meeting the 100-year requirements for urban development.

During a high-water event on the San Joaquin River in January 1997, seepage and boils occurred at several locations along the RD 17 levees. The USACE, California Department of Water Resources (DWR), and RD 17 successfully contained the seepage and boils, and the levees did not break. After the 1997 event, the USACE, the Central Valley Flood Protection Board (CVFPB), and RD 17 funded a project, the Reconstruction of the California Central Valley Levees San Joaquin Basin #4, Reclamation District #17 Project, to repair the seepage and boil areas. The project was designed and constructed by USACE, and work was completed in 2003.

After reviewing the data supporting the 1990 accreditation and subsequent information, FEMA notified RD 17 of its intention to confirm full accreditation of the RD 17 levees as meeting FEMA's requirements for 100-year flood protection. On June 19, 2007, DWR wrote a letter to the City of Lathrop, with a copy to FEMA, stating that it could not support recertification of the RD 17 levees or the granting of provisional accreditation because of concerns about seepage exit gradients[1]. The basis of DWR's concern was analysis showing seepage exit gradients greater than 0.5, which indicated a higher likelihood of seepage or boils occurring during a high-water event. Because of DWR's concern, FEMA then denied full accreditation and instead granted provisional accredited levee (PAL) status to the RD 17 levees. A PAL is a levee that FEMA has previously credited with providing a 100-year flood event level of flood risk reduction (i.e., flood with a 1 percent chance of occurring in any given year, or 0.01 AEP). In fall 2007, in response to the PAL status, RD 17 initiated a levee seepage repair program (LSRP) and requested funding through DWR's Early Implementation Program.

RD 17 subsequently implemented Phases 1 and 2 of the LSRP. After completion of the Phase 1 and 2 levee repairs, RD 17 submitted a recertification application to FEMA. In September 2010, RD 17 received a response letter declaring that FEMA had accredited the area protected by the RD 17 levee system associated with phases 1 and 2, including the dryland levee, thereby removing the PAL status for these sections of levee. Phase 3 of the LSRP will address the remaining sections of levee in RD 17 that have seepage deficiencies that do not meet the current USACE seepage criteria standards and levee geometry requirements.

We completed pre-dissemination review of this document using standards for utility, integrity, and objectivity in compliance with applicable guidelines issued under the Data Quality Act (DQA) (section 515 of the Treasury and General Government Appropriations Act for Fiscal Year 2001, Public Law 106-554). The document will be available through the NMFS Public Consultation Tracking System website.[2] A complete record of this consultation is on file at the California Central Valley Area Office.

1.2 Consultation History

The list below summarizes correspondence, meetings, and discussions between regulatory agencies, RD 17, and consultants that relate to potential effects of the Phase 3 of the RD 17 Levee Seepage Repair Project (Project) on species addressed in this document.

---

[1] Seepage exit gradient" is an expression in numeric form of the potential for under seepage to exit on the landside of a levee as seepage or a boil. The lower the number used to express seepage exit gradient, the more resistant the system is to seepage or boils; the higher the number, the more likely seepage or boils may occur during a high water event. In formulas for seepage exit gradients, the numerator (top number in a fraction) typically addresses forces that cause or enhance seepage (e.g., water pressure), and the denominator typically addresses forces that resist seepage (e.g., soil resistance to water pressure, depth and weight of soil over the potential seepage area, distance from the levee toe). A lower seepage exit gradient (i.e., more resistance to seepage) is achieved when the numerator (positive seepage forces) is reduced and/or the denominator (resistance to seepage) is increased.

[2] Once on the PCTS homepage, use the following PCTS tracking number within the Quick Search column: WCR-2018-10630, or search for the project by name: Phase 3 RD 17 Levee Seepage Repair Project.

5/14/10 Letter from AECOM, prepared on behalf of RD 17, to US Fish and Wildlife Service (USFWS) and NMFS requesting informal technical assistance in evaluating the potential effects on listed species that could result from implementing USACE vegetation management standards, and in developing a conservation strategy to adequately offset the potential loss of habitat. Copies of the wetland delineation report and maps were provided with the letter.

6/11/10 Letter from NMFS to AECOM, responding to the May 14, 2010, letter requesting technical assistance for the Project.

8/24/10 Meeting between representatives of USACE, USFWS, NMFS, and AECOM to discuss the potential effects of the project on listed species and development of a conservation strategy.

3/1/11 Tour of proposed action area with representatives from AECOM, USACE, USFWS, NMFS, and California Department of Fish and Wildlife (CDFW).

3/27/15 Letter from USACE to NMFS transmitting the Biological Assessment (BA) and requesting informal consultation for the Project and concurrence that the Project was "not likely to adversely affect" the federally listed threatened Central Valley (CV) spring-run Chinook salmon evolutionarily significant unit (ESU) (*Oncorhynchus tshawytscha*), endangered Sacramento River winter-run Chinook salmon ESU (*O. tshawytscha*), threatened California CV (CCV) steelhead distinct population segment (DPS) (*O. mykiss*), and the threatened southern DPS (sDPS) of North American green sturgeon (*Acipenser medirostris*). The USACE also determined that the proposed Project would not result in the destruction or adverse modification of designated critical habitat for any of these species and would not adversely affect EFH of Pacific salmon under section 305(b)(2) of the MSA.

7/7/2015 NMFS sent a letter to the USACE indicating that the materials provided were insufficient to conduct a consultation for the Project and requested additional information regarding the Project.

10/7/2016 A response to the NMFS insufficiency letter of 7/7/15 requesting additional information was completed by GEI Consultants and AECOM, on behalf of RD 17, and sent to NMFS.

3/8/2017 USACE submits a new request to USFWS and NMFS to re-initiate informal Section 7 consultation. The request includes submittal of a revised BA. NMFS informs USACE that this consultation will be delayed due to NMFS staff being detailed to work on the California Water Fix consultation.

3/22/2017 USACE advised NMFS of anticipated emergency construction in RD 17 to protect levee integrity during high water events that winter.

4/6/2017 Authorization from USACE issued to RD 17 for discharge of fill into waters of the United States for the 2017 Emergency Response Construction Project (SPK-2009-001466) under Regional General Permit No. 8 (Emergency Actions).

9/22/2017 Email correspondence with USACE indicating that NMFS staff will re-engage with the RD 17 consultation following completion of the California Water Fix consultation. NMFS staff requests explanations regarding the amount of work done for emergency repairs during the previous winter's high flood flows on the San Joaquin River.

11/2/2017 USACE responds that the applicant is revising the BA to reflect emergency work done on the levees in the RD 17 Levee Seepage Repair Project area during the previous winter

12/11/2017 Meeting with representatives from USACE, NMFS, and GEI Consultants to discuss the BA and Section 7 consultation with NMFS.

1/12/2018 USACE provided USFWS and NMFS with copies of the Conceptual Mitigation and Monitoring Plan (Conceptual MMP), and requested their review of the document.

3/14/2018 NMFS provided the USACE with comments on the Conceptual MMP.

4/30/2018 A response to comments was completed by GEI Consultants, on behalf of RD 17, and included as an appendix to the proposed Project's updated BA.

5/16/2018 NMFS issued a letter to the USACE indicating that the RD 17 consultation had been closed out due to inactivity.

8/21/2018 USACE provided a new request for informal consultation for the Project with an enclosed BA containing updated information related to the emergency repairs conducted during the winter of 2017. The USACE requested concurrence from NMFS that the Project was "not likely to adversely affect" the federally listed threatened CV spring-run Chinook salmon ESU, endangered Sacramento River winter-run Chinook salmon ESU, threatened CCV steelhead DPS, and the threatened sDPS of North American green sturgeon. The USACE also determined that the proposed Project will not result in the destruction or adverse modification of designated critical habitat for any of these species and will not adversely affect EFH of Pacific salmon under section 305(b)(2) of the MSA.

9/27/2018 NMFS sent a letter to the USACE indicating that it did not concur with their request for a concurrence with a "not likely to adversely affect" determination for the Project. NMFS however concluded that there was sufficient information contained in the BA to initiate formal consultation with the USACE on this Project. NMFS informed the USACE that a biological opinion will be completed on or before January 3, 2019.

1/28/2019	NMFS initiated consultation on September 18, 2018, however, the consultation was held in abeyance for 38 days due to a lapse in appropriations and resulting partial government shutdown. Consultation resumed on January 28, 2019.

1.3 Proposed Action

"Action" means all activities or programs of any kind authorized, funded, or carried out, in whole or in part, by Federal agencies (50 CFR 402.02).

1.3.1 Federal Action

RD 17, in cooperation with DWR and the CVFPB, is the local project sponsor for the Project. RD 17 has requested permission from the CVFPB and USACE to alter segments of the San Joaquin River levee system within the district's boundaries, which are part of the federal project levee system. The proposed action for USACE is to make a combined permit decision on the Project under the authority of a Clean Water Act Section 404 (33 USC 1344) permit and a Section 10 of the Rivers and Harbors Act of 1899 (33 USC 403) permit for placement of fill into jurisdictional waters of the United States, as well as a permission decision under Section 14 of the Rivers and Harbors Act of 1899 (33 USC 408), referred to as a Section 408, for alterations of federal projects. Under Section 408, the USACE may allow the permanent use or occupancy of a USACE flood risk management project with approval by the Secretary of the Army on the recommendation of the Chief of Engineers, provided that such use or occupancy would not be injurious to the public interest.

1.3.2 Project Location

RD 17 is located in south-central San Joaquin County, California, at the north end of the San Joaquin River Basin, and within the far southeast limit of the Delta (Figure 1). The boundaries of RD 17 are marked by French Camp Slough on the north, approximately 3 miles southwest of the central business district of the City of Stockton; the San Joaquin River on the west; Walthall Slough on the south (just below State Route 120); and Airport Way/McKinley Avenue on the east, just outside the City of Manteca. RD 17 is responsible for maintaining the levees along the east bank of the San Joaquin River from just south of Mathews Road to Walthall Slough, the levees along the north bank of Walthall Slough, and the dryland levee out to approximately South Airport Way. The locations of levee repairs that are part of the three phases of the LSRP are shown in Figure 2.

The proposed actions associated with the Project are located along specific reaches of the RD 17 levees, as depicted in Figure 2. The Project's landside levee improvements would occur along 5.2 miles (27,456 feet) of the RD 17 levee system and would involve constructing: 17,020 feet of cutoff walls; 940 feet of seepage berms; 8,280 feet of chimney drains; 1,100 feet of new setback levee; and, placing fill on the landside slope of the levees wherever needed to achieve engineering design standards for slope gradient and levee profile. The proposed action would also include: grading 8 acres of offset area (area between the existing levee and a new setback levee); restoring 9.9 to 11.5 acres of native vegetation in the offset area; degrading 400 feet of existing levee; raising a PG&E high voltage tower footing; and, replacing a wooden railroad trestle bridge with a new embankment. Table 1 describes this information in greater detail by project element (i.e., reach). The proposed action would eliminate or reduce levee deficiencies, including through- and under-seepage, slope stability, erosion, and encroachments within the construction footprint. Table 1 also includes descriptions of those portions of the Phase 3 actions that were part of the emergency actions taken in the winter of 2017, as well as the actions within each element that remain to be completed by the Project. The Phase 3 features that have not yet been constructed are the focus of this consultation with the USACE.

Table 1: RD 17 Levee Seepage Repair Project Construction Elements

Comparison of all Major RD 17 Phase 3 Levee Repair Project Features with Those Features Completed as Emergency Actions in 2017 and Those Features Remaining to be Completed (and which are the subject of this consultation)				
Element	**Type of Remediation**	**Phase 3 Project Major Features**	**Phase 3 Project Features Constructed as 2017 Emergency Response Actions**	**Phase 3 Project Features Remaining To be Constructed1**
Ia	under seepage and through seepage	Construct approximately 590 feet of seepage berm (approximately 110 feet wide) and approximately 590 feet of chimney drain to meet required exit gradients. Construct PG&E high voltage tower footing raisings. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.	Constructed approximately 350 feet of seepage berm to meet required exit gradients. The constructed seepage berm width is approximately 110 feet.	Construct approximately 240 feet of additional seepage berm (approximately 110 feet wide) and approximately 590 feet of chimney drain to meet required exit gradients. Construct PG&E high voltage tower footing raisings. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.
Ib	under seepage and through seepage	Fill existing depression to approximately 300 feet from toe of existing levee. Construct approximately 130 feet of seepage berm (approximately 80 feet wide) and approximately 130 feet of chimney drain on top of fill to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.	Filled existing depression to approximately 300 feet from toe of existing levee. Constructed approximately 130 feet of seepage berm on top of fill to meet required exit gradients. The constructed seepage berm width is approximately 80 feet.	Construct approximately 130 feet of chimney drain to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.
Ie	under seepage and through seepage	Construct approximately 590 feet of seepage berm (approximately 70 feet wide) and approximately 590 feet of chimney drain to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.	Constructed approximately 590 feet of seepage berm to meet required exit gradients. The constructed seepage berm width is approximately 70 feet.	Construct approximately 590 feet of chimney drain to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.
IIab	under seepage and through seepage	Construct approximately 2,600 feet of cutoff wall to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.	*None.*	Construct approximately 2,600 feet of cutoff wall to meet required exit gradients. Depth of cutoff wall would vary from 40–60 feet. Cutoff wall would involve degrading top 1/3 to 1/2 of levee crown and would begin with 1:1 cut at waterside crown. Place levee fill material along landside of existing levee slope where feasible to provide minimum 3:1 slope and 20-foot levee crown width.

1.3.3 Project Purpose and Objectives

The overall purpose of the Project is to implement landside and isolated waterside levee improvements in 19 LSRP elements affecting 5.2 miles of the approximately 19-mile RD 17 levee system, leading to the reduction of flooding risk in the RD 17 service area during a 100-year flood event. Levee improvements would address under seepage, through seepage, and levee geometry repair and remediation. USACE and RD 17 each view the project purpose from the purview of their respective responsibilities, defined as follows:

USACE's objectives for the Project are to:

- decide whether or not to grant permission for the Project to alter the federal project levees within its levee system under Section 408, and;
- decide whether or not to issue combined permits under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act of 1899.

RD 17's objectives for the proposed Project are to:

- repair seepage deficiencies where needed to meet current USACE seepage criteria standards;
- increase the levee's resistance to under seepage and/or through seepage;
- provide under seepage exit gradients equal to or less than 0.5 at the landside levee toe, and equal to or less than 0.8 at the landside drainage seepage berm at the water surface elevation associated with the design water surface, and;
- meet levee geometry requirements of the permitting agencies in the specific areas of repair work.

1.3.4 Construction Actions Related to the Project Elements

The Project would address the under seepage and/or through seepage concerns raised by DWR and repair and/or remediate levee geometry to USACE design standards along approximately 5.2 miles of the RD 17 levee system, including portions of the San Joaquin River east levee and portions of the levee along the northern bank of Walthall Slough. Under seepage occurs below the above-ground levee prism and is caused by the buildup of water pressure in the subsurface foundation soils when high-river stages are present on the waterside of the levees. This pressure head causes water to flow through the earthen foundation layers under the levee and exit onto the ground surface on the landside of the levee prism (Figure 3). Such seepage is not uncommon and does not inherently imply that the levee is failing; however, excessive and uncontrolled under seepage can carry fine-grained material with the water flow that can undermine the levee and lead to levee failure. Through seepage is the movement of water through the levee prism when high-river stage conditions exist on the waterside of the levee (Figure 3). Depending on the duration of high water and the permeability of the levee embankment soil, seepage may exit onto the landside slope of the levee, thereby negatively affecting the stability of the landside levee slope.
Levee improvements along the USACE project levees would consist primarily of in-place repair/remediation actions, but would include a single setback levee at element IVc. As summarized in Table 1 and shown in Figures 4a through 4c, the Project's landside levee improvements would include a combination of construction of seepage berms, installation of

chimney drains and both shallow and deep cutoff walls, the raising of the landside grade, and construction of a setback levee with a seepage berm and an underlying cutoff wall along 19 elements of the RD 17 levee system. These levee repair components, as well as additional project components (such as levee geometry corrections and stormwater management), are described in more detail in the following sections. The proposed Project does not include any work that would raise the existing levee. Limited work would be performed along the waterside of the levee above the ordinary hide tide line (HTL) in element IVc, where the setback levee would be constructed and new floodplain created.

1.3.4.1 Seepage Berms

A drained seepage berm collects and conveys seepage that comes through the levee, thereby reducing the flood risk associated with a high-water event. Drained seepage berms are built on the landside of a levee, and consist of layers of sand filter material, drain rock, geosynthetic filter fabric, and a seepage berm soil fill (Figure 5). The design width and height of a seepage berm are dependent on the relative permeability of the underlying soil layers and the amount of pressure head that push water under the levee and through these soils during sustained high-river events. The higher the water pressure head and the more dissimilar the porosity of the underlying soil layers, the wider and/or taller the seepage berm must be to prevent boils and reduce flood risk.

For the Project, drained seepage berm widths of 60–120 feet are expected to be adequate to meet the design criteria in most cases (Figure 5). However, these types of berms may extend up to 300–400 feet inland from the landside toe of the levee. Seepage berms typically are constructed using select materials excavated from borrow sites or obtained from commercial sources. For the Project, soil material for seepage berms would be purchased from commercial sources and hauled to the construction sites by dump trucks. A compacted-surface patrol road would be constructed near the outside edge of the seepage berm (see “Additional Project Components” below).

In urban areas, some seepage berms also would include a toe drain system (element VIIg) to safely collect and discharge the seepage water into an urban storm drainage system. A toe drain pipe is a below-grade, perforated pipe surrounded by a layer of sand and drain rock (Figure 6). The toe drain pipe is a mechanism to safely collect and convey seepage water away from the levee and seepage berm. If the toe drain pipe is unable to convey the seepage water, the water exits the drained seepage berm through the drain rock at the face of the berm, similar to a nonurban berm.

1.3.4.2 Chimney Drains

A chimney drain is a drainage system that collects seepage waters that are flowing through the above-ground portion of the levee structure. This type of drain is used to collect and convey through seepage. A chimney drain consists of a 1 to 3-foot-thick layer of sand and drain rock. Filter fabric is placed between the soil and rock layer to avoid migration of the soil into the rock, which can clog the rock layer and reduce its ability to carry seepage flows. The chimney drain is placed directly on the landside slope of the levee and tied into an existing or new drained seepage berm at the landside base of the levee (Figure 7). The chimney drain conveys the through seepage flows to a drained seepage berm, which is located at the landside base of the levee as described in the previous section.

Installing a chimney drain in an existing drained seepage berm would include adding the through seepage material on top of the existing seepage berm and tying this material into the existing seepage berm material by removing the seepage berm fill material and physically tying the two drainage rock layers together. When the remediation includes construction of a new drained seepage berm with a chimney drain, the chimney drain would be installed during construction of the drained seepage berm.

1.3.4.3 Cutoff Walls

In selected locations of the Project, cutoff walls would be placed through the levee prism (parallel to the river). Cutoff walls use specialized earthen materials to create an impermeable barrier to under or through seepage in the levee (often bentonite clay, which has low permeability, or a mixture of bentonite and cement). Cutoff walls would be constructed vertically through the levee prism, extending into or through deeper foundational soils that have low-permeability (a layer through which seepage does not flow readily). Thus, cutoff walls would substantially reduce the potential for under and through seepage flow during high-river flow events. Two methods for installing cutoff walls would be used along portions of the RD 17 levees: the conventional open-trench method and the deep soil mixing method.

The conventional open-trench method would be used to install shallow cutoff walls to a maximum depth of approximately 80 feet. This method involves excavating material in an open trench (the trench is filled with a bentonite slurry to maintain the side slopes of the excavation) and then replacing it with the select materials, typically a bentonite or cement-bentonite slurry (Figure 8). Prior to excavating the open trench, the top one-third to one-half of the levee prism height is "degraded," meaning that it is excavated so that any weakness in the narrow upper portion of the levee does not result in failure of the levee during the cutoff wall construction. Following construction of the cutoff wall, the levee is restored to its original height and the levee prism constructed to achieve USACE criteria for crown width and slope gradient.

For the deep slurry mixing method, specialized equipment (such as a crane mounted auger) is used to excavate deep into the subsurface soils, allowing the cutoff walls to reach depths up to 120 feet below grade (Figure 9). The deep slurry mixing method involves mixing the loosened soil in place with cement and/ or bentonite, thereby reducing the risk of failure during construction. This method does not require levee crown degradation.

For the Project, the cutoff walls would be extended approximately 300 feet beyond the element boundary to provide the required overlap with drained seepage berms that have been or are being installed along the landside sections of adjacent levee elements. Levee slopes (where cutoff walls would be installed) also would be modified as needed to achieve the required 20-feet levee crown width and landside slope of 3:1.

1.3.4.4 Setback Levee with Seepage Berm and Cutoff Wall

Project Element IVc involves construction of a 1,100-foot-long setback levee with an underlying cutoff wall and a seepage berm, on a major oxbow of the San Joaquin River (Table 1). In the Project area, soil materials beneath a setback levee are anticipated to have properties similar to those of materials below the existing levees. Therefore, a setback levee would have no seepage-related benefit in the RD 17 area relative to other seepage control methods. Like the existing levees, a setback levee would require either a cutoff wall or drained seepage berm to sufficiently reduce the potential adverse effects associated with under seepage flows (Figures 10 and 11). Nevertheless, implementation of a setback levee could provide some additional capacity in the river for floodwaters and also would have the potential to provide habitat in the area between the new and old levee locations.

Where the new setback levee would intersect the existing levee bordering the San Joaquin River, the top one-third to one-half of the crown of the existing levee would be degraded beginning with a 1:1 cut at the existing waterside crown to facilitate tying the cutoff wall and setback levee into the existing levee. Approximately 0.64 acres (740 linear feet) of riprap would be installed only on the waterside of the existing levee and above the HTL in element IVc where it would intersect the setback levee. No trees/shrubs would be removed to place the riprap and any riprap around trees/shrubs would be hand-placed. The riprap would not be installed to act as launchable rock. After the setback levee is completed, 400 linear feet of the existing levee above the HTL on the downstream side of the oxbow would be degraded, reconnecting approximately 6 acres of floodplain to the river.

The reconnected floodplain area would be graded to allow complete drainage of the floodplain to the river after high water events that inundated the floodplain. As flood flows recede, the floodplain area would drain completely through the breach in the remnant levee. It is anticipated that this design feature will minimize the possibility of fish stranding on the floodplain (Figure 12).

The Conceptual MMP evaluated three breach invert elevations (8 feet [North American Vertical Datum 1988 {NAVD88}], 10 feet [NAVD88] and 14 feet [NAVD88]) for the proposed levee breach on the downstream end of the oxbow. Hydraulic modeling, based on San Joaquin River flows as reported at the Vernalis U.S. Geological Survey (USGS) stream gage (Vernalis gage), about 17.5 miles upstream of the project area, was used to estimate the flow in the San Joaquin River at which water would enter the setback area through the remnant levee breach for the three breach invert elevations investigated (Table 2).

To evaluate how often and how long the levee setback area would be expected to be inundated, historical Vernalis gage daily flow records were reviewed since the completion of New Melones Dam in 1979. This represents a period of time where the San Joaquin River basin operating regime has changed relatively little and portrays current reservoir operations. The evaluation used the mean daily flows for the period October 1, 1978 through September 30, 2015, or Water Years 1979 through 2015. The total number of days in the evaluation period is 13,514. Table 3 summarizes the estimated number and percent of days in the evaluation study period in which the levee setback area would flood based on the three potential invert elevations.

The appropriate breach elevation is under consideration and will be defined in the Final MMP. It is anticipated that the breach elevation would be set at approximately 9 or 10 feet (NAVD88). Approximately 1-2 acres of the floodplain would be set to an elevation of 14 feet (NAVD88) or below and would inundate approximately every 6 years.

Table 2: Estimated Flows for Inundation of the Element IVc Mitigation Site

Estimated Flows for Inundation

1.3.4.5 Additional Project Components

The following activities will occur as part of the proposed Project in addition to the construction of seepage berms, chimney drains, cutoff walls, and the setback levee with its new floodplain area:

- **Levee geometry corrections:** Several of the Project elements currently do not meet requirements for levee geometry (i.e., slopes, crown width). To correct levee geometry deficiencies, levee fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot- wide levee crown. All levee elements would undergo some level of levee geometry corrections.

- **Operations and Maintenance (O&M) access and utility corridors**: A 20-foot-wide permanent O&M access corridor would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.

- **Temporary construction easements**: Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the site(s) would be returned to pre-project conditions following completion of construction.

- **Stormwater /irrigation controls**: Drainage/irrigation swales would be constructed around the outside boundaries of levee repairs, where needed, and other stormwater best management practices (BMPs) would be implemented to manage stormwater runoff and/or irrigation during and after construction. These swales would be located so that they would not drain to/from wetlands or other waters of the U.S.

- **Haul roads**: An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and cement) would be required to construct these levee improvements. These materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would be public roadways, on and within 300 feet of the levees, existing unpaved roads used for access to work areas, and levee patrol roads atop the levee crown.

- **Landside vegetation removal**: Landside vegetation within the footprint of the proposed levee work, including maintenance roadway corridors and temporary access easements, would be cleared to prepare for levee repair work. The proposed action would involve performing limited work on the waterside of the levee above the HTL (e.g., installing riprap and degrading a portion of the levee in element IVc); however, no waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover. Figures 13a through 13c show the relevant vegetation types at each Project element location.

- **Encroachment management**: Several features, including power poles, vegetation, and a variety of agricultural-related facilities (e.g., irrigation infrastructure, fences), are within the Project footprint. Utility infrastructure would be relocated as needed to accommodate the levee repairs, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Project area would be removed or relocated as required to meet the criteria of USACE, the CVFPB, and FEMA. No waterside woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Long-Term Vegetation Management**: Vegetation on the levees and within the access easements would be managed in accordance with current O&M practices to maintain access and visibility. These practices include: mechanical trimming of existing trees and removal of large dead and downed trees annually; regular summer and winter application of herbicides for weed control; and summer application of herbicides to control woody plants and berries.

1.3.5 Proposed Construction Schedule and Sequence of Project Construction

The Project is expected to take 2 years to complete the construction actions with an additional year required for site restoration and demobilization. The general levee construction window is seasonal (July 1–November 1), avoiding the period when high-water levels have the potential to occur within the San Joaquin River system. However, the Project applicant has stated that depending on hydrologic conditions and subject to compliance with species work windows, a work window variance that allows an extension outside the July 1–November 1 work period may be granted by the CVFPB. The CVFPB may stipulate that RD 17 has to comply with additional conditions and commitments as a component of any work window variance.

The proposed construction sequence, which would include concurrent work in several different Project elements to meet the project schedule, is as follows:

- **Relocation of power poles**: Power poles currently situated on the landside of the levee toe of some elements would need to be relocated to accommodate the proposed drained seepage berms. To the extent feasible, power poles would be relocated beyond the toe of the new berm, outside the maintenance access easement. If placing poles on top of the seepage berms is required, either raised foundations or steel-reinforced concrete piers would be constructed to prevent the poles from affecting the seepage berms. RD 17 would oversee relocation of the power poles, in coordination with the appropriate utility and construction companies.

- **Site preparation at existing levee sites and in levee setback area**: Site preparation (i.e., clearing, grubbing, and stripping) of the levee elements would begin by clearing structures (see discussion in the next bullet) and woody vegetation from the footprint of the proposed levee work and the permanent O&M access and utility corridors. Vegetation would be retained in areas adjacent to but outside the project footprint. This operation would require removal of some trees and relocation or removal of some elderberry shrubs. Large trees would be felled approximately 3 feet above ground level, with stumps temporarily left in place. Where feasible, small trees and elderberry shrubs would be relocated. Relocation of elderberry shrubs would be done according to guidelines from the USFWS. A minimal amount of below-ground disturbance would occur. The clearing operation would be followed by grubbing operations to remove stumps, root balls, and any below-ground infrastructure. The area then would be disked to chop surface vegetation and mix it with near-surface organic soils. The disking operation would be followed by stripping the top 12 inches of earthen material from the landside slope of the existing levee and the footprint of the proposed seepage berms. Excess earthen materials (i.e., organic soils, and excavated material that does not meet levee embankment criteria) would be temporarily stockpiled and then would be re-spread on the surface of the new levee slopes and seepage berms, provided this material is not contaminated with vegetation. Any stripped material contaminated with vegetation and other debris generated during the clearing and grubbing operations would be hauled off-site to a suitable landfill.

- **Removal or modification of landside structures and other facilities:** In a few levee elements, agricultural facilities (e.g., fences, drainage infrastructure) or parking lots are located within the footprint of the proposed levee work. These facilities would be removed from or relocated outside the project footprint before levee construction begins in those areas. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Demolished concrete could be sent to a concrete recycling facility. If any wells or septic systems would be affected, they would be abandoned in accordance with the applicable State and County requirements.

- **Construction of the setback levee with drained seepage berm and underlying cutoff wall**: Construction of the setback levee embankment in element IVc would begin as soon as sufficient lengths of levee foundation are prepared and weather conditions are suitable. Foundation preparation would include constructing a levee keyway that would be excavated 3–5 feet deep across the entire footprint of the proposed setback levee with excavators or bulldozers. A smaller but deeper excavated inspection trench, centered beneath the new waterside hinge point of the setback levee, would be constructed beneath a small portion of the keyway at that location to meet DWR standards. After the foundation layers are backfilled with engineered soil, a geotechnical geogrid fabric would be installed at ground level across the entire setback levee footprint. A second layer of geogrid fabric would be placed at mid-height of the new levee fill section to further reduce the potential for post-construction settlement of the new levee. The embankment would be constructed of engineered fill, with the fill placed in 3-foot-maximum lifts by motor graders. Each lift would be moisture-conditioned using water trucks and would be compacted to the specified density using a suitable compactor, such as a sheep’s foot, tamping foot, or rubber-tired roller. Next, quarry stone riprap would be applied in three segments, to armor the newly completed setback levee’s waterside slope and protect against erosion. Riprap would be placed on the waterside levee above the HTL in areas that are characterized by ruderal land cover (Figure 12). All waterside woodland would be avoided; all waterside trees would be avoided as well as any tree canopy that overlaps riprap. Riprap placement would be done either by barge or by long-arm excavator from the top of the levee crown. Riprap dimensions for the three segments are: 340 feet long by 50 feet wide (0.39 acre), 140 feet long by 30 feet wide (0.096 acre), and 230 feet long by 50 feet wide (0.26 acre). A drained seepage berm then would be constructed on the landside of the setback levee. Fill material for setback levee and drained seepage berm construction would be obtained from commercial sources and would be delivered to levee construction sites using haul trucks.

- **Setback levee site restoration and demobilization:** After completion of construction, the previously stripped topsoil material would be placed on top of the completed setback levee and associated seepage berms in element IVc, and levee slopes and the tops of the seepage berms would be hydroseeded. An aggregate-base patrol road would be constructed at the landside edge of the seepage berm and setback levees and on the new setback levee crown. The existing levee would be fully restored at the tie-in points to the new setback levee. The existing levee crown patrol road would be redressed with aggregate base, to restore it to preconstruction levels. Any disturbed riprap also would be supplemented to provide a uniform layer across the connection point with the new setback levee. Immediately after final construction, the setback levee's fill slopes would be covered with erosion control material until application of the hydroseed. Any construction debris would be hauled to an appropriate off-site waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization would be likely to occur in various locations as construction proceeds along various elements.

- **Removal of existing levee at setback levee elements, site restoration, and demobilization**: After certification of the new setback levee and seepage berm in element IVc, a 400-linear-foot-long section of the existing outboard levee (which is approximately 2,400 linear feet long in element IVc) on the downstream side of the existing oxbow would be partially degraded using earth moving equipment. The area where the levee would be degraded is characterized by ruderal land cover (Figure 13b); some landside vegetation would be removed, but all waterside trees and overlapping tree canopy would be avoided. Except for an approximately 20-foot-wide corridor on the top of the remnant levee that will serve as a maintenance road, providing access to the remnant levee breach area for maintenance and flood fighting purposes, at least 9.9 acres (and up to 11.1 acres) of riparian vegetation would be established in the area between the new setback levee and the San Joaquin River (Figure 12) (see the "Compensation Measures" subsection of the "Avoidance and Minimization Measures" section below for additional information). This acreage would be made up of approximately 6.1 acres of restored riparian scrub habitat between the landside toe of the existing levee and the waterside toe of the new setback levee and between the river and the waterside toe of the existing levee, and approximately 5 acres of restored Great Valley oak woodland/upland refugia habitat along either side of the existing levee. These acreages would include approximately 1.2 acres of contingency land area, with the goal of restoring a minimum of 9.9 acres of riparian habitat. This work would be completed after flood season (from July 1 through November 1) and above the HTL, primarily using scrapers, excavators, and bulldozers to remove the levee section and all present levee encroachments.

- **Construction of drained seepage berms, drained seepage berms with chimney drains, and chimney drains within existing drained seepage berms**: Fill material for levee improvements would be obtained from commercial sources and delivered to the levee construction sites by haul trucks. The material then would be spread by motor graders and compacted by sheep's foot rollers to build new seepage berms and seepage berms with chimney drains. A water truck would be used to properly moisture-condition the soils for compaction. Installing the chimney drains in existing drained seepage berms also would require use of an excavator or scraper to remove the existing drained seepage berm fill material so that the chimney drain fill material can be tied into the drainage rock layer of the existing drained seepage berm.

- **Construction of cutoff walls**: Equipment required for cutoff wall construction would include slurry batch plants to prepare bentonite or bentonite cement mix, pumps, and support vehicles. Four to five batch plants or slurry ponds would be required for the project; these would be located near the site of cutoff wall construction. Each batch plant or slurry pond with associated pumps and support equipment would occupy an area of approximately 100 square feet that would be restored to pre-project conditions following completion of cutoff wall construction. Cutoff walls may be installed concurrently in two or more different directions within an element. RD 17 proposes to use the deep slurry mix method for installing deep cutoff walls, which would avoid the need to degrade the top of the levee, and conventional slurry trench walls (open-cut method) for shallow cutoff walls. RD 17 also would consider driving sheet piles, using a drop impact hammer or other pile-driving technology in lieu of cutoff wall installation at element VIIe. The number of cutoff wall rig setups would depend on the project schedule and contractor preference. Each deep slurry mix cutoff wall rig would move continuously along the proposed alignment, to attain an uninterrupted cutoff wall and reduce prolonged disturbance to residences near some cutoff wall segments. Each cutoff wall rig could move 50 to 100 feet horizontally during a 12-hour work shift, while each conventional slurry trench rig could move 75 to 200 feet horizontally during a 12-hour work shift. Cutoff wall construction in Elements Va and VIa.1 is anticipated to occur 24 hours a day, 7 days a week, with occasional shutdowns for equipment maintenance, when necessary. Lights and possibly power generators would be used during nighttime construction hours. Disturbances to nearby residences are expected to be minor because of the limited number of residences near these cutoff wall installation areas. However, where lights, noise, and/or vibration would exceed allowable nighttime standards for the applicable local jurisdiction, work hours would be restricted to daytime work hours.

- **Site restoration and demobilization**: On completion of construction, previously stripped topsoil material not contaminated with vegetation would be placed on top of the completed seepage berms and any disturbed levee slopes. Any previously nonagricultural, vegetated areas disturbed during construction would be hydroseeded with a standard erosion control mix. An aggregate-base patrol road would be constructed at the landside edge of any seepage berms. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization likely would occur in various locations as construction proceeds along various elements.

1.3.6 Avoidance and Minimization Measures

1.3.6.1 General

- A qualified biologist, retained by RD 17, will be on-site to ensure compliance with the avoidance and minimization measures described below, particularly where construction activities occur adjacent to sensitive habitats to be avoided.

- A worker awareness training program will be conducted for construction crews before the start of construction. The program will include a brief overview of special-status species and sensitive resources (including riparian habitats) in the Project area, measures to avoid and minimize effects on those resources, and conditions of relevant regulatory permits.

1.3.6.2 Federally Listed Fish Species – Anadromous Salmonids, and North American Green Sturgeon

The following measures will be implemented to avoid and minimize potential adverse effects related to lights, noise, and vibration:

- During nighttime construction, RD 17 will use shielded lighting that is directed away from the waterside levees.

- Vibratory compaction equipment will be specifically restricted on the RD 17 levees. The limited amount of compaction that would occur on landside chimney drain locations would be restricted to normal work day hours.

The following measures will be implemented to avoid and minimize potential adverse effects on water quality:

- Any work within the existing floodway (i.e., placing riprap on the waterside levee above the HTL at element IVc) of the San Joaquin River will not take place during the designated flood season (i.e., November 1 to July 1) and will not begin until evaluation of upstream conditions (e.g., reservoir storage and snowpack) indicate that inundation of these areas will be unlikely to occur during construction.

- RD 17 will comply with all local, State, and federal regulations and environmental requirements regarding turbidity-reduction measures, including the following:

    - obtaining and complying with relevant agency permits (e.g., CDFW streambed alteration agreement, Central Valley Regional Water Quality Control Board [RWQCB] Clean Water Act Section 401 certification, and Section 404 permit);

    - developing and implementing a storm water pollution prevention plan (SWPPP) that identifies specific BMPs to avoid and minimize effects on water quality during construction activities; and,

    - complying with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity.

- RD 17 will file a notice of intent with the Central Valley RWQCB to discharge stormwater associated with construction activity. Final design and construction specifications will require implementation of standard erosion, siltation, and good housekeeping BMPs. Construction contractors will be required to prepare and implement a SWPPP and comply with the conditions of the NPDES general stormwater permit for construction activity (Order No. 2009-0009-DWQ or the current permit in place at the time of construction). The SWPPP will describe the construction activities to be conducted, BMPs that will be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that will be conducted. At a minimum, the following specific BMPs will be implemented:

- All work will be conducted according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized.
- Silt fences and/or straw wattles will be installed near riparian areas or existing drainages to control erosion and trap sediment and reseed cleared areas with native vegetation.
- Maintenance will be conducted on a regular basis to ensure proper installation and function of BMPs, and during storm events, maintenance will be conducted daily.
- BMPs that have failed (within 48 hours of an event) will be repaired and replaced immediately with sufficient devices and materials (e.g., silt fence, coir rolls, and erosion blankets), provided throughout project construction to enable immediate corrective action for failed BMPs.
- Stockpiling of construction materials (e.g., portable equipment, vehicles, and supplies, including chemicals) will be restricted to designated construction staging areas, exclusive of any riparian, wetland, or other areas supporting waters.
- Disturbed soils at construction areas will be stabilized before the onset of rainfall.
- Stockpiles will be stabilized and protected from exposure to rain and potential erosion.

The SWPPP also will specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of effects from use or accidental spills or releases of contaminants. Specific measures applicable to the project will include the following:

- Compliance will be required by RD 17 contractors with all applicable State Water Resources Control Board (SWRCB) and Central Valley RWQCB standards and other applicable water quality standards.
- Strict on-site handling rules will be developed and implemented, to keep potentially contaminating construction and maintenance materials out of drainages and other waterways.
- When refueling and servicing equipment, absorbent material or drip pans will be used underneath such equipment to contain spilled fuel, oil, and other fluids; and any fluid drained from machinery will be collected in leak-proof containers and delivered to an appropriate disposal or recycling facility.
- Substances that can be hazardous to aquatic life will be prevented from contaminating the soil or entering watercourses.
- Spill cleanup equipment will be maintained in proper working condition. All spills will be cleaned up immediately according to the spill prevention and response plan, which

will be prepared by RD 17 or its contractor or representative and will be approved by the Central Valley RWQCB before the start of project ground- breaking.

- NMFS, USFWS, CDFW, and the Central Valley RWQCB will be notified immediately (within 24 hours) of any reportable spills and cleanup occurrences. All such spills, and the success of the efforts to clean them, will be recorded in post-construction compliance reports.

- A slurry spill contingency plan will be developed, which will be prepared by RD 17 or its contractor or representative before the start of project groundbreaking, to respond to a potential for bentonite slurry spill and prevent slurry from entering watercourses.

- Construction materials handled by RD 17 or its contractors will be stored and transported in a manner that minimizes potential water quality effects. Storage areas will be located away from drainages and waterways, outside the floodplain, and away from sensitive resources, and containment facilities will be used.

BMPs will be applied to meet the “maximum extent practicable” and “best conventional technology/best available technology” requirements and address compliance with water quality standards. RD 17 will implement a monitoring program during and after construction so that the Project complies with all applicable standards and ensures that the implementation of the BMPs are effective.

1.3.6.3 Mitigation and Monitoring Plan

A Conceptual MMP has been prepared to describe the expansion and restoration of riparian habitat in element IVc. Specifically, this plan:

- describes specifications for the restoration of habitat components, including details about the restoration of riparian habitats, with a list of the plant species and drawings/designs to show the location of the plant species and planting density;

- establishes specific success criteria for the habitat components, including:

    - performance standards to determine whether the habitat improvement was trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions);

    - monitoring and maintenance protocols; and

    - measurable goals to ensure vegetation survival to provide and replace riparian habitats;

- specifies remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring); and

- describes short and long-term management and maintenance of the habitat lands.

The Conceptual MMP is intended to be developed into a Final MMP, in coordination with USFWS, NMFS, and USACE, and would be reviewed and approved by USFWS and NMFS before ground-breaking in the portions of the Project area that could affect the species addressed in this opinion. RD 17 would provide conservation of the restored riparian habitat in the levee setback area in element IVc. The compensation habitat ultimately would be transferred to a suitable land management organization, for long-term management and monitoring.

1.3.7 Interrelated and Interdependent Actions

"Interrelated actions" are those that are part of a larger action and depend on the larger action for their justification. "Interdependent actions" are those that have no independent utility apart from the action under consideration (50 CFR 402.02). There are no interdependent or interrelated actions associated with the Project.

2 ENDANGERED SPECIES ACT: BIOLOGICAL OPINION AND INCIDENTAL TAKE STATEMENT

The ESA establishes a national program for conserving threatened and endangered species of fish, wildlife, plants, and the habitat upon which they depend. As required by section 7(a)(2) of the ESA, each Federal agency must ensure that its actions are not likely to jeopardize the continued existence of endangered or threatened species, or adversely modify or destroy their designated critical habitat. Per the requirements of the ESA, Federal action agencies consult with NMFS and section 7(b)(3) requires that, at the conclusion of consultation, NMFS provides an opinion stating how the agency's actions would affect listed species and their critical habitats. If incidental take is reasonably certain to occur, section 7(b)(4) requires NMFS to provide an ITS that specifies the impact of any incidental taking and includes non-discretionary reasonable and prudent measures (RPMs) and terms and conditions to minimize such impacts.

2.1 Analytical Approach

This biological opinion includes both a jeopardy analysis and/or an adverse modification analysis. The jeopardy analysis relies upon the regulatory definition of "to jeopardize the continued existence of" a listed species, which is "to engage in an action that would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (50 CFR 402.02). Therefore, the jeopardy analysis considers both survival and recovery of the species.

This biological opinion relies on the definition of "destruction or adverse modification," which "means a direct or indirect alteration that appreciably diminishes the value of critical habitat for the conservation of a listed species. Such alterations may include, but are not limited to, those that alter the physical or biological features essential to the conservation of a species or that preclude or significantly delay development of such features" (81 FR 7214).

The designations of critical habitat for Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon uses the term primary constituent element (PCE) or essential features. The new critical habitat regulations (81 FR 7414) replace this term with physical or biological features (PBFs). The shift in terminology does not change the approach used in conducting a ''destruction or adverse modification'' analysis, which is the same regardless of whether the original designation identified PCEs, PBFs, or essential features. In this biological opinion, we use the term PBF to mean PCE or essential feature, as appropriate for the specific critical habitat.

We use the following approach to determine whether a proposed action is likely to jeopardize listed species or destroy or adversely modify critical habitat:

- Identify the rangewide status of the species and critical habitat expected to be adversely affected by the proposed action.
- Describe the environmental baseline in the action area.

- Analyze the effects of the proposed action on both species and their habitat using an "exposure-response-risk" approach.
- Describe any cumulative effects in the action area.
- Integrate and synthesize the above factors by: (1) Reviewing the status of the species and critical habitat; and (2) adding the effects of the action, the environmental baseline, and cumulative effects to assess the risk that the proposed action poses to species and critical habitat.
- Reach a conclusion about whether species are jeopardized or critical habitat is adversely modified.
- If necessary, suggest a RPA to the proposed action.

2.2 Range wide Status of the Species and Critical Habitat

This opinion examines the status of each species that would be adversely affected by the proposed action. The status is determined by the level of extinction risk that the listed species face, based on parameters considered in documents such as recovery plans, status reviews, and listing decisions. This informs the description of the species' likelihood of both survival and recovery. The species status section also helps to inform the description of the species' current "reproduction, numbers, or distribution" as described in 50 CFR 402.02. The opinion also examines the condition of critical habitat throughout the designated area, evaluates the conservation value of the various watersheds and coastal and marine environments that make up the designated area, and discusses the current function of the essential PBFs that help to form that value for the conservation of the listed species.

The following Federally listed species ESU, DPSs, and designated critical habitats occur in the action area and have the potential to be affected by the action (Table 4):

Table 4: ESA Listing History

Species	ESU or DPS	Original Final FR Listing	Current Final Listing Status	Critical Habitat Designated
Chinook salmon (*O. tshawytscha*)	Central Valley spring-run ESU	9/16/1999 64 FR 50394 Threatened	6/28/2005 70 FR 37160 Threatened	9/2/2005 70 FR 52488 (Not Present in Action Area)
Steelhead (*O. mykiss*)	California Central Valley DPS	3/19/1998 63 FR 13347 Threatened	1/5/2006 71 FR 834 Threatened	9/2/2005 70 FR 52488
Green sturgeon (*Acipenser medirostris*)	Southern DPS	4/7/2006 71 FR 17757 Threatened	4/7/2006 71 FR 17757 Threatened	10/9/2009 74 FR 52300

2.2.1 Central Valley Spring-run Chinook salmon

- Listed as threatened (September 16, 1999, 64 FR 50394), reaffirmed (June 28, 2005, 70 FR 37160).
- Designated critical habitat (September 2, 2005, 70 FR 52488)

The Federally listed ESU of Central Valley (CV) spring-run Chinook salmon ESU occurs in the action area and may be affected by the proposed action. Designated critical habitat does not occur in the action area. Detailed information regarding ESU listing and critical habitat designation history, designated critical habitat, ESU life history, and VSP parameters can be found in NMFS' 2014 Recovery Plan (NMFS 2014).

Historically, spring-run Chinook salmon were the second most abundant salmon run in the Central Valley and one of the largest on the west coast (CDFG 1990). These fish occupied the upper and middle elevation reaches (1,000 to 6,000 feet) of the San Joaquin, American, Yuba, Feather, Sacramento, McCloud and Pit rivers, with smaller populations in most tributaries with sufficient habitat for over-summering adults (Stone 1874, Rutter 1902, Clark 1929). The Central Valley drainage as a whole is estimated to have supported spring-run Chinook salmon runs as large as 600,000 fish between the late 1880s and 1940s (CDFG 1998). The San Joaquin River historically supported a large run of spring-run Chinook salmon, suggested to be one of the largest runs of any Chinook salmon on the West Coast with estimates averaging 200,000 500,000 adults returning annually (CDFG 1990).

Monitoring of the Sacramento River mainstem during spring-run Chinook salmon spawning timing indicates some spawning occurred in the river (CDFW 2018), but has been essentially non-existent since 2008/2009. Genetic introgression has likely occurred here due to lack of physical separation between spring-run and fall-run Chinook salmon populations (CDFG 1998). Sacramento River tributary populations in Mill, Deer, and Butte creeks are likely the best trend indicators for the CV spring-run Chinook salmon ESU. Generally, these streams have shown a positive escapement trend since 1991, displaying broad fluctuations in adult abundance (CDFW 2018). The Feather River Fish Hatchery (FRFH) spring-run Chinook salmon population represents an evolutionary legacy of populations that once spawned above Oroville Dam. The FRFH population is included in the ESU based on its genetic linkage to the natural spawning population, and the potential for development of a conservation strategy (June 28, 2005, 70 FR 37160).

The Central Valley Technical Review Team (TRT) estimated that historically there were 18 or 19 independent populations of CV spring-run Chinook salmon, along with a number of dependent populations, all within four distinct geographic regions, or diversity groups (Lindley et al. 2004). Of these populations, only three independent populations currently exist (Mill, Deer, and Butte creeks tributary to the upper Sacramento River) and they represent only the northern Sierra Nevada diversity group. Additionally, smaller populations are currently persisting in Antelope and Big Chico creeks, and the Feather and Yuba rivers in the northern Sierra Nevada diversity group (CDFG 1998).

In the San Joaquin River basin, observations in the last decade suggest that spring-running populations may still occur in the Stanislaus and Tuolumne rivers (Franks 2013). Currently, attempts to reintroduce an experimental population of CV spring-run Chinook salmon to the San Joaquin River basin are underway. A final rule was published to designate a nonessential experimental population of CV spring-run Chinook salmon to allow reintroduction of the species below Friant Dam on the San Joaquin River as part of the San Joaquin River Restoration Project (SJRRP) (78 FR 79622; December 31, 2013). Pursuant to ESA section 10(j), with limited exceptions, each member of an experimental population shall be treated as a threatened species. However, the rule includes proposed protective regulations under ESA section 4(d) that would provide specific exceptions to prohibitions under ESA section 9 for taking CV spring-run Chinook salmon within the experimental population area (San Joaquin River from Friant Dam downstream to the confluence of the Merced River), and in specific instances elsewhere. The first release of CV spring-run Chinook salmon juveniles into the San Joaquin River occurred in April 2014. A second release occurred in 2015, and future releases are planned to continue annually during the spring. Natural spawning of adult CV spring-run below Friant Dam on the San Joaquin River has been observed (presence of redds) in the last two years (2017, 2018). The SJRRP's future long-term contribution to the CV spring-run Chinook salmon ESU has yet to be determined, but is likely to include individuals present in the Project action area in future years.

The CV spring-run Chinook salmon ESU is comprised of two known genetic complexes. Analysis of natural and hatchery spring-run Chinook salmon stocks in the Central Valley indicates that the northern Sierra Nevada diversity group spring-run Chinook salmon populations in Mill, Deer, and Butte creeks retain genetic integrity as opposed to the genetic integrity of the Feather River population, which has been somewhat compromised by introgression with the fall-run ESU (Good et al. 2005, Garza et al. 2008, Cavallo et al. 2011).

Because the populations in Butte, Deer and Mill creeks are the best trend indicators for ESU viability, we can evaluate the risk of extinction based on VSP parameters in these watersheds. Over the long term, these three remaining populations are considered to be vulnerable to anthropogenic and naturally occurring catastrophic events. The viability assessment of CV spring-run Chinook salmon conducted during NMFS' 2010 status review (NMFS 2011a), found that the biological status of the ESU had worsened since the last status review (2005) and recommended that the species status be reassessed in two to three years as opposed to waiting another five years, if the decreasing trend continued. In 2012 and 2013, most tributary populations increased in returning adults, averaging approximately 19,000 fish in-river (CDFW 2018). However, 2014 returns were lower again, just over 7,000 fish in -river, indicating the ESU population remains highly fluctuating. The most recent status review was conducted in 2015 (NMFS 2016a), which looked at promising increasing populations for the period between 2012 and 2014. However, the 2015 returning in-river adult fish escapement was extremely low (1,195 fish), with additional pre-spawn mortality reducing populations even more. Since the effects of the 2012-2016 drought have not been fully realized, we anticipate at least several more years of very low returns, which may result in severe rates of decline (NMFS 2016a). Adult escapements for in-river adult spring-run escapement is 6,453 fish for 2016, but only 1,105 fish for 2017 (CDFW 2018). These returns are substantially lower than the cohort returns three years earlier.

Spring-run Chinook salmon adults are vulnerable to climate change because they over-summer in freshwater streams before spawning in autumn (Thompson et al. 2011). CV spring-run Chinook salmon spawn primarily in the tributaries to the Sacramento River, and those tributaries without cold water refugia (usually input from springs) will be more susceptible to impacts of climate change. Even in tributaries with cool water springs, in years of extended drought and warming water temperatures, unsuitable conditions may occur. Additionally, juveniles often rear in the natal stream for one to two summers prior to emigrating, and would be susceptible to warming water temperatures. In Butte Creek, fish are limited to low elevation habitat that is currently thermally marginal, as demonstrated by high summer mortality of adults in 2002 and 2003, and will become intolerable within decades if the climate warms as expected. Ceasing water diversion for power production from the summer holding reach in Butte Creek resulted in cooler water temperatures, more adults surviving to spawn, and extended population survival time (Mosser et al. 2013).

2.2.1.1 Summary of the Central Valley Spring-run Chinook salmon ESU Viability

In summary, the recent 5-year Status Review described the extinction risk for the CV spring-run Chinook salmon ESU as remaining at moderate risk of extinction (NMFS 2016a). Based on the severity of the drought and the low escapements as well as increased pre-spawn mortality in Butte, Mill, and Deer creeks in 2015, there is concern that these CV spring-run Chinook salmon strongholds will deteriorate into high extinction risk in the coming years based on the population size or rate of decline criteria (NMFS 2016a). This postulate is supported by the sharp declines in adult escapement for the years 2014 through 2017 for each cohort (CDFW 2018).

2.2.1.2 Critical Habitat and Physical or Biological Features for Central Valley Spring-run Chinook salmon

The critical habitat designation for CV spring-run Chinook salmon lists the PBFs (June 28, 2005, 70 FR 37160), which are described in NMFS' 2014 Recovery Plan (NMFS 2014). In summary, the PBFs include freshwater spawning sites, freshwater rearing sites, freshwater migration corridors, and estuarine habitat. The geographical range of designated critical habitat includes stream reaches of the Feather, Yuba, and American rivers, Big Chico, Butte, Deer, Mill, Battle, Antelope, and Clear creeks, and the Sacramento River, as well as portions of the northern Delta (June 28, 2005, 70 FR 37160). Waterways described in the listing for spring-run critical habitat do not include the southern Delta or lower San Joaquin River which are part of the action area.

2.2.1.3 Summary of the Value of CV Spring-run Chinook salmon Critical Habitat for the Conservation of the Species

Currently, many of the PBFs of CV spring-run Chinook salmon critical habitat are degraded, and provide limited high quality habitat. Features that lessen the quality of migratory corridors for juveniles include unscreened or inadequately screened diversions, altered flows in the Delta, scarcity of complex in-river cover, and the lack of floodplain habitat. Although the current conditions of CV spring-run Chinook salmon critical habitat are significantly degraded, the spawning habitat, migratory corridors, and rearing habitat that remain are considered to have high intrinsic value for the conservation of the species. However, the action area does not include waterways designated as critical habitat for CV spring-run Chinook salmon.

2.2.2 *California Central Valley Steelhead*

- Originally listed as threatened (March 19, 1998, 63 FR 13347); reaffirmed as threatened (January 5, 2006, 71 FR 834).
- Designated critical habitat (September 2, 2005, 70 FR 52488).

The Federally listed DPS of CCV steelhead and designated critical habitat for this DPS occurs in the action area and may be affected by the proposed action. Detailed information regarding DPS listing and critical habitat designation history, designated critical habitat, DPS life history, and VSP parameters can be found in the NMFS' 2014 Recovery Plan (NMFS 2014).

Historic CCV steelhead run sizes are difficult to estimate given the paucity of data, but may have approached one to two million adults annually (McEwan 2001). By the early 1960s the CCV steelhead run size had declined to about 40,000 adults (McEwan 2001). Current abundance data for CCV steelhead is limited to returns to hatcheries and redd surveys conducted on a few rivers. The hatchery data is the most reliable because redd surveys for steelhead are often made difficult by high flows and turbid water usually present during the winter-spring spawning period.

Overall CCV steelhead returns to the Coleman National Fish Hatchery (CNFH), which includes both wild and hatchery origin fish, have increased over the four-year period, 2011 to 2014. After hitting a low of only 790 fish in 2010, the last two years prior to the most recent 5-year review, 2013 and 2014, have averaged 2,895 fish. Wild adults counted at the hatchery each year represent a small fraction of overall returns, but their numbers have remained relatively steady, typically 200–300 fish each year. Numbers of wild adults returning each year have ranged from 252 to 610 from 2010 to 2014.

Redd counts are conducted in the American River and in Clear Creek (Shasta County). An average of 143 redds have been counted on the American River from 2002–2015 [data from Hannon et al. (2003), Hannon and Deason (2008), Chase (2010), Cramer Fish Sciences 2015, NMFS 2016b]. An average of 178 redds have been counted in Clear Creek from 2001 to 2015 following the removal of Saeltzer Dam, which allowed steelhead access to additional spawning habitat. The Clear Creek redd count data ranges from 100-1,023 and indicates an upward trend in abundance since 2006 (NMFS 2016b).

The returns of CCV steelhead to the Feather River Hatchery experienced a sharp decrease from 2003 to 2010, with only 679, 312, and 86 fish returning in 2008, 2009 and 2010, respectively. In recent years, however, returns have experienced an increase with 830, 1,797, and 1,505 fish returning in 2012, 2013, and 2014 respectively. Overall, steelhead returns to hatcheries have fluctuated so much from 2001 to 2015 that no clear trend is present.

An estimated 100,000 to 300,000 naturally produced juvenile CCV steelhead are estimated to leave the Central Valley annually, based on rough calculations from sporadic catches in trawl gear (Good et al. 2005). Nobriga and Cadrett (2001) used the ratio of adipose fin-clipped (hatchery) to unclipped (wild) CCV steelhead smolt catch ratios in the USFWS Chipps Island trawl from 1998 through 2000 to estimate that about 400,000 to 700,000 CCV steelhead smolts are produced naturally each year in the Central Valley. Trawl data indicate that the level of natural production of CCV steelhead has remained very low since the 2011 status review (NMFS 2016b), suggesting a decline in natural production based on consistent hatchery releases. Catches of CCV steelhead at the fish collection facilities in the southern Delta are another source of information on the production of wild CCV steelhead relative to hatchery CCV steelhead (data is found on the CDFW Fish Salvage Monitoring website). The overall catch of CCV steelhead has declined dramatically since the early 2000s, with an overall average of 2,705 in the last 10 years. The percentage of wild (unclipped) fish in salvage has fluctuated, but has leveled off to an average of 36 percent since a high of 93 percent in 1999. In 2018 (as of 5/22/18 – last recorded steelhead smolt for WY18), the total number of unclipped steelhead observed in salvage is 1,037. The number of clipped steelhead observed in salvage is 728 fish, which may indicate that 2017 (a wet year) had a strong year class for wild steelhead production.

About 80 percent of the historical spawning and rearing habitat once used by anadromous *O. mykiss* in the Central Valley is now upstream of impassible dams (Lindley et al. 2006). Many historical populations of CCV steelhead are entirely above impassable barriers and may persist as resident or adfluvial rainbow trout, although they are presently not considered part of the DPS. CCV steelhead are well-distributed throughout the Central Valley below the major rim dams (Good et al. 2005, NMFS 2016b). Most of the CCV steelhead populations in the Central Valley have a high hatchery component, including Battle Creek (adults intercepted at the Coleman NFH weir), American River, Feather River, and Mokelumne River, all of which have hatchery steelhead production programs.

CCV steelhead abundance and growth rates continue to decline, largely the result of a significant reduction in the amount and diversity of habitats available to these populations (Lindley et al. 2006). Recent reductions in population size are supported by genetic analysis (Nielsen et al. 2003). Garza and Pearse (2008) analyzed the genetic relationships among CCV steelhead populations and found that unlike the situation in coastal California watersheds, fish below barriers in the Central Valley were often more closely related to below barrier fish from other watersheds than to *O. mykiss* above barriers in the same watershed. This pattern suggests the ancestral genetic structure is still relatively intact above barriers, but may have been altered below barriers by stock transfers. The genetic diversity of CCV steelhead is also compromised by hatchery origin fish, placing the natural population at a high risk of extinction (Lindley et al. 2007). Historically, steelhead in the Central Valley consisted of both summer-run and winter-run migratory forms. Currently, only winter-run (ocean maturing) steelhead are found in California Central Valley rivers and streams as summer-run have been extirpated (McEwan and Jackson 1996, Moyle 2002).

CCV steelhead will experience similar effects of climate change as do Chinook salmon in the Central Valley, as they are also blocked from the vast majority of their historic spawning and rearing habitat. The effects may be even greater in some cases, as juvenile steelhead need to rear in their natal stream for one to two summers prior to emigrating as smolts. In the Central Valley, summer and fall temperatures below the dams in many streams already exceed the recommended temperatures for optimal growth of juvenile steelhead, which range from 14°C to 19°C (57°F to 66°F). Several studies have found that steelhead require colder water temperatures for spawning and embryo incubation than salmon (McCullough et al. 2001). In fact, McCullough et al. (2001) recommended an optimal incubation temperature at or below 11°C to 13°C (52°F to 55°F).

Successful smoltification in steelhead may be impaired by temperatures above 12°C (54°F), as reported in Richter and Kolmes (2005). As stream temperatures warm due to climate change, the growth rates of juvenile steelhead could increase in some systems that are currently relatively cold, but potentially at the expense of decreased survival due to higher metabolic demands and greater presence and activity of predators. Stream temperatures that are currently marginal for spawning and rearing may become too warm to support wild steelhead populations in the future.

2.2.2.1 Summary of California Central Valley Steelhead DPS Viability

All indications are that natural CCV steelhead have continued to decrease in abundance and in the proportion of natural fish observed compared to hatchery produced fish over the past 25 years (NMFS 2016b); the long-term trend remains negative. Hatchery production and returns are the dominant components of the Central Valley population structure. Most wild CCV populations are very small and may lack the resiliency to persist for protracted periods of time if subjected to additional stressors, particularly widespread stressors such as climate change. The genetic diversity of CCV steelhead has likely been impacted by low population sizes and high numbers of hatchery fish relative to wild fish.

In summary, the status of the CCV steelhead DPS appears to have remained unchanged since the 2011 status review, and the DPS is likely to become endangered within the foreseeable future throughout all or a significant portion of its range (NMFS 2016b).

2.2.2.2 Critical Habitat and Physical or Biological Features for California Central Valley Steelhead

The critical habitat designation for CCV steelhead lists the PBFs (June 28, 2005, 70 FR 37160), which are described in NMFS' 2014 Recovery Plan (NMFS 2014). In summary, the PBFs include freshwater spawning sites; freshwater rearing sites; freshwater migration corridors; and estuarine areas. The geographical extent of designated critical habitat includes: the Sacramento, Feather, and Yuba rivers, and Deer, Mill, Battle and Antelope creeks in the Sacramento River basin; the San Joaquin River, including its tributaries but excluding the mainstem San Joaquin River above the Merced River confluence; and the waterways of the Delta.

2.2.2.3 Summary of the Value of California Central Valley Steelhead Critical Habitat for the Conservation of the species

Many of the PBFs of CCV steelhead critical habitat are currently degraded and provide limited high quality habitat. Passage to historical spawning and juvenile rearing habitat has been largely eliminated due to construction of impassable dams throughout the Central Valley. Levee construction has also degraded the value for the conservation of the species of freshwater rearing and migration habitat and estuarine areas as riparian vegetation has been removed, reducing habitat complexity, food resources, and resulting in many other detrimental ecological effects. Contaminant loading and poor water quality in Central California waterways poses threats to steelhead, their habitat, and their food resources. Additionally, due to reduced access to historical habitats, genetic introgression is occurring because naturally-produced fish are interacting with hatchery-produced fish which has the potential to reduce the long-term fitness and survival of this species.

Although the current conditions of CCV steelhead critical habitat are significantly degraded, the spawning habitat, migratory corridors, and rearing habitat that remain in the Sacramento/San Joaquin River watersheds and the Delta are considered to have high intrinsic value for the conservation of the species as they are critical to the ongoing recovery effort.

2.2.3 *Southern Distinct Population Segment of North American Green Sturgeon*

- Listed as threatened (April 7, 2006, 71 FR 17757).
- Critical habitat designated (October 9, 2009, 74 FR 52300).

The federally listed sDPS of North American green sturgeon and designated critical habitat for this DPS occurs in the action area and may be affected by the proposed action. Detailed information regarding DPS listing and critical habitat designation history, designated critical habitat, and DPS life history can be found on the following web site: NOAA Fisheries West Coast Region Green Sturgeon web page.

Green sturgeon are known to range from Baja California to the Bering Sea along the North American continental shelf. During late summer and early fall, subadults and non-spawning adult green sturgeon can frequently be found aggregating in estuaries along the Pacific coast (Emmett et al. 1991, Moser and Lindley 2007). Using polyploid microsatellite data, Israel et al. (2009) found that green sturgeon within the Central Valley of California belong to the sDPS. Additionally, acoustic tagging studies have found that green sturgeon found spawning within the Sacramento River are exclusively sDPS green sturgeon (Lindley et al. 2011). In waters inland from the Golden Gate Bridge in California, sDPS green sturgeon are known to range through the estuary and the Delta and up the Sacramento, Feather, and Yuba rivers (Israel et al. 2009, Bergman et al. 2011, Seesholtz et al. 2015). It is unlikely that green sturgeon utilize areas of the San Joaquin River upriver of the Delta with regularity, and spawning events are thought to be limited to the upper Sacramento River and its tributaries. There is no known modern usage of the San Joaquin River upstream of the Delta by green sturgeon, and adult spawning has not been documented there (Jackson and Van Eenennaam 2013). However, a confirmed sighting of a green sturgeon based on visual observation, video documentation, and positive eDNA samples occurred in the fall of 2017 on the Stanislaus River (FishBio 2017). This sighting helps to corroborate reports of green sturgeon being caught by anglers on the San Joaquin River upstream of the Delta on the CDFW's sturgeon report cards which are required for the sport fishing of sturgeon in California (Gleason et al. 2008, DuBois et al. 2009, DuBois et al. 2010, Dubois et al. 2011, DuBois et al. 2012, DuBois 2013, DuBois et al. 2014, DuBois and Harris 2015, DuBois and Harris 2016, DuBois and Danos 2017, and DuBois and Danos 2018)

Recent research indicates that the sDPS is composed of a single, independent population, which principally spawns in the mainstem Sacramento River and also breeds opportunistically in the Feather River and possibly even the Yuba River (Bergman et al. 2011, Seesholtz et al. 2015). Concentration of adults into a very few select spawning locations makes the species highly vulnerable to poaching and catastrophic events. The apparent, but unconfirmed, extirpation of spawning populations from the San Joaquin River narrows the available habitat within their range, offering fewer habitat alternatives. Whether sDPS green sturgeon display diverse phenotypic traits such as ocean behavior, age at maturity, and fecundity, or if there is sufficient diversity to buffer against long-term extinction risk is not well understood. It is likely that the diversity of sDPS green sturgeon is low, given recent abundance estimates (NMFS 2015).

Trends in abundance of sDPS green sturgeon have been estimated from two long-term data sources: (1) salvage numbers at the State and Federal pumping facilities (see below), and (2) by incidental catch of green sturgeon by the CDFW white sturgeon sampling/tagging program. Historical estimates from these sources are likely unreliable because the sDPS was likely not taken into account in incidental catch data, and salvage does not capture range-wide abundance in all water year types. A decrease in sDPS green sturgeon abundance has been inferred from the amount of take observed at the south Delta pumping facilities: the Skinner Delta Fish Protection Facility, and the Tracy Fish Collection Facility. This data should be interpreted with some caution. Operations and practices at the facilities have changed over the decades, which may affect salvage data. These data likely indicate a high production year vs. a low production year qualitatively, but cannot be used to rigorously quantify abundance.

Since 2010, more robust estimates of sDPS green sturgeon have been generated. As part of a doctoral thesis at UC Davis, Ethan Mora has been using acoustic telemetry to locate green sturgeon in the Sacramento River, and to derive an adult spawner abundance estimate (Mora et al. 2015). Preliminary results of these surveys estimate an average annual spawning run of 223 (DIDSON camera) and 236 (telemetry) fish. This estimate does not include the number of spawning adults in the lower Feather or Yuba Rivers, where green sturgeon spawning was recently confirmed (Seesholtz et al. 2015).

The parameters of green sturgeon population growth rate and carrying capacity in the Sacramento Basin are poorly understood. Larval count data shows enormous variance among sampling years. In general, sDPS green sturgeon year class strength appears to be highly variable with overall abundance dependent upon a few successful spawning individuals (NMFS 2010b). Other indicators of productivity such as data for cohort replacement ratios and spawner abundance trends are not currently available for sDPS green sturgeon.

Southern DPS green sturgeon spawn primarily in the Sacramento River in the spring and summer. Anderson-Cottonwood Irrigation District Diversion Dam (ACID) is considered the upriver extent of green sturgeon passage in the Sacramento River (71 FR 17757, April 7, 2006). The upriver extent of green sturgeon spawning, however, is approximately 30 kilometers downriver of ACID where water temperature is higher than ACID during late spring and summer (Heublein et al. 2017a). Thus, if water temperatures increase with climate change, temperatures adjacent to ACID may remain within tolerable levels for the embryonic and larval life stages of green sturgeon, but temperatures at spawning locations lower in the river may be more affected. It is uncertain, however, if green sturgeon spawning habitat exists closer to ACID, which could allow spawning to shift upstream in response to climate change effects. Successful spawning of green sturgeon in other accessible habitats in the Central Valley (i.e., the Feather River) is limited, in part, by late spring and summer water temperatures (NMFS 2015). Similar to salmonids in the Central Valley, green sturgeon spawning in tributaries to the Sacramento River is likely to be further limited if water temperatures increase and higher elevation habitats remain inaccessible.

2.2.3.1 Summary of Green Sturgeon DPS Viability

The viability of sDPS green sturgeon is constrained by factors such as a small population size, lack of multiple populations, and concentration of spawning sites into just a few locations. The risk of extinction is believed to be moderate (NMFS 2010a). Although threats due to habitat alteration are thought to be high and indirect evidence suggests a decline in abundance, there is much uncertainty regarding the scope of threats and the viability of population abundance indices (NMFS 2010b). Lindley et al. (2007), in discussing Sacramento River winter-run Chinook salmon, states that an ESU (or DPS) represented by a single population at moderate risk of extinction is at high risk of extinction over a large timescale; this would apply to the sDPS for green sturgeon. The most recent 5 year status review for sDPS green sturgeon found that some threats to the species have recently been eliminated, such as take from commercial fisheries and removal of some passage barriers (NMFS 2015). Since many of the threats cited in the original listing still exist, the threatened status of the DPS is still applicable (NMFS 2015).

2.2.3.2 Critical Habitat and Physical or Biological Factors for sDPS Green Sturgeon

The critical habitat designation for sDPS green sturgeon lists the PBFs (October 9, 2009, 74 FR 52300), which are described on the NOAA Fisheries West Coast Region's green sturgeon page. In summary, the PBFs include the following for both freshwater riverine systems and estuarine habitats: food resources, water flow, water quality, migratory corridor, depth, and sediment quality. Additionally, for riverine systems, the designation includes substrate type or size. In addition, the PBFs include migratory corridor, water quality, and food resources in nearshore coastal marine areas. The geographical range of designated critical habitat includes the following.

In freshwater, the geographical range includes:

- the Sacramento River from the Sacramento I-Street bridge to Keswick Dam, including the Sutter and Yolo bypasses and the lower American River from the confluence with the mainstem Sacramento River upstream to the highway 160 bridge;
- Feather River from its confluence with the Sacramento River upstream to Fish Barrier Dam;
- Yuba River from its confluence with the Feather River upstream to Daguerre Point Dam; and,
- the Sacramento-San Joaquin Delta (as defined by California Water Code section 12220, except for listed excluded areas).

In coastal bays and estuaries, the geographical range includes:

- San Francisco, San Pablo, Suisun, and Humboldt bays in California,
- Coos, Winchester, Yaquina, and Nehalem bays in Oregon,

- Willapa Bay and Grays Harbor in Washington, and the
- lower Columbia River estuary from the mouth to river kilometer 74.

In coastal marine waters, the geographical range includes all U.S. coastal marine waters out to the 60-fathom depth bathymetry line from Monterey Bay north and east to include waters in the Strait of Juan de Fuca, Washington.

2.2.3.3 Summary of the Value of sDPS Green Sturgeon Critical Habitat for the Conservation of the Species

Currently, many of the PBFs of sDPS green sturgeon are degraded and provide limited high quality habitat. Additional features that lessen the quality of migratory corridors for juveniles include unscreened or inadequately screened diversions, altered flows in the Delta, and presence of contaminants in sediment. Although the current conditions of green sturgeon critical habitat are significantly degraded, the spawning habitat, migratory corridors, and rearing habitat that remain in both the Sacramento/San Joaquin River watersheds, the Delta, and nearshore coastal areas are considered to have high intrinsic value for the conservation of the species.

2.2.4 Global Climate Change

One factor affecting the range-wide status of CCV steelhead, CV spring-run Chinook salmon, and the sDPS of the North American green sturgeon, and aquatic habitat at large is climate change.

The world is about 1.3°F warmer today than a century ago and the latest computer models predict that, without drastic cutbacks in emissions of carbon dioxide and other gases released by the burning of fossil fuels, the average global surface temperature may rise by two or more degrees in the 21st century (IPCC 2001, 2007). Much of that increase likely will occur in the oceans, and evidence suggests that the most dramatic changes in ocean temperature are now occurring in the Pacific (Noakes et al. 1998). Using objectively analyzed data Huang and Liu (2001) estimated a warming of about 0.9°F per century in the Northern Pacific Ocean.

Sea levels are expected to rise by 0.5 to 1.0 meters in the northeastern Pacific coasts in the next century, mainly due to warmer ocean temperatures, which lead to thermal expansion much the same way that hot air expands. This will cause increased sedimentation, erosion, coastal flooding, and permanent inundation of low-lying natural ecosystems (e.g., salt marsh, riverine, mud flats) affecting listed salmonid and green sturgeon PBFs. Increased winter precipitation, decreased snow pack, permafrost degradation, and glacier retreat due to warmer temperatures will cause landslides in unstable mountainous regions and destroy fish and wildlife habitat, including salmon-spawning streams. Glacier reduction could affect the flow and temperature of rivers and streams that depend on glacier water, with negative impacts on fish populations and the habitat that supports them.

Summer droughts along the West Coast and in the interior Central Valley of California will mean decreased stream flow in those areas, decreasing salmonid survival and reducing water supplies in the dry summer season when irrigation and domestic water use are greatest. Global warming may also change the chemical composition of the water that fish inhabit: the amount of oxygen in the water may decline, while pollution, acidity, and salinity levels may increase. This will allow for more invasive species to overtake native fish species and impact predator-prey relationships (Petersen and Kitchell 2001, Stachowicz et al. 2002).

In light of the predicted impacts of global warming, the Central Valley has been modeled to have an increase of between 2 and 7°C by 2100, with a drier hydrology predominated by rainfall rather than snowfall (Dettinger et al. 2004, Hayhoe et al. 2004, VanRheenen et al. 2004, Stewart et al. 2005). This will alter river runoff patterns and transform the tributaries that feed the Central Valley from a spring and summer snowmelt dominated system to a winter rain dominated system. It can be hypothesized that summer temperatures and flow levels will become unsuitable for salmonid survival. The cold snowmelt that furnishes the late spring and early summer runoff will be replaced by warmer precipitation runoff. This will truncate the period of time that suitable cold-water conditions exist downstream of existing reservoirs and dams due to the warmer inflow temperatures to the reservoir from rain runoff. Without the necessary cold water pool developed from melting snow pack filling reservoirs in the spring and early summer, late summer and fall temperatures downstream of reservoirs, such as Lake Shasta, could potentially rise above thermal tolerances for juvenile and adult salmonids that must hold and/or rear downstream of the dam over the summer and fall periods.

Projected warming is expected to affect Central Valley Chinook salmon. Because the runs are restricted to low elevations as a result of impassable rim dams, if climate warms by 5°C (9°F), it is questionable whether any Central Valley Chinook salmon populations can persist (Williams 2006). Based on an analysis of an ensemble of climate models and emission scenarios and a reference temperature from 1951- 1980, the most plausible projection for warming over Northern California is 2.5°C (4.5°F) by 2050 and 5°C by 2100, with a modest decrease in precipitation (Dettinger 2005). Chinook salmon in the Central Valley are at the southern limit of their range, and warming will shorten the period in which the low elevation habitats used by naturally-producing Chinook salmon are thermally acceptable. This would particularly affect fish that emigrate as fingerlings, mainly in May and June, and especially those in the San Joaquin River and its tributaries. Specific climate change impacts have already been described in the rangewide status of the species and critical habitat sections for each species (Sections 2.2.1 through 2.2.3).

In summary, observed and predicted climate change effects are generally detrimental to the species (McClure 2011, Beechie et al. 2012,Wade et al. 2013), so unless offset by improvements in other factors, the status of the species and critical habitat is likely to decline over time. The climate change projections referenced above cover the time period between the present and approximately 2100. While there is uncertainty associated with projections, which increases over time, the direction of change is relatively certain (McClure et al. 2013).

2.3 Action Area

"Action area" means all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 CFR 402.02). The action area is not the same as the project boundary area because the action area must delineate all areas where federally-listed populations of salmon, steelhead, and green sturgeon may be affected by the implementation of the action.

RD 17 is located in south-central San Joaquin County, California, at the north end of the San Joaquin River Basin, and within the far southeast limit of the Delta. The extent of the action area during the construction phase of the Project extends from the farthest downstream construction area (Element 1a; approximately River Mile [RM] 46) which is located on the eastern levee paralleling the San Joaquin River, just to the north of the Howard Road Bridge spanning the San Joaquin River (Figures 2 and 4a). The extent of impacts from construction actions is expected to extend no more than 1,000 feet downstream of this location due to the propagation of noise and vibrations into the adjacent river channel from construction of chimney drains and seepage berms. The upstream boundary of the action area during the construction phase of the Project is located just upstream of Element VIIe. This element location is on the eastern bank of the San Joaquin River at the junction of Walthall Slough and the mainstem San Joaquin River (RM 57) (Figures 2 and 4c). Construction of deep slurry walls at this location is expected to propagate noise and vibrations approximately 2000 feet upstream in the San Joaquin River to the next river bend (latitude 37.77374º, longitude -121.30467º). The action area during the 2-year construction phase of the Project will impact the 11.5 miles of river channel between Element 1a and Element VIIe, as multiple construction sites are located along this reach of the San Joaquin River and the Project description indicates that construction will occur simultaneously at these sites during the 2 years of the proposed Project.

The long term action area of the Project following completion of the construction phase will be the area encompassed by the setback levee at Element IVc. This encompasses no more than approximately 6.1 acres of created floodplain between the landside toe of the existing levee, and the waterside toe of the newly constructed setback levee, and the waterside toe of the existing levee adjacent to the San Joaquin River. Duration and frequency of inundation of the newly created floodplain will depend on the final design elevation of the floodplain. The setback levee is located at approximately RM 52.5 (latitude 37.814525º, longitude -121.317369º).

2.4 Environmental Baseline

The "environmental baseline" includes the past and present impacts of all Federal, state, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7 consultation, and the impact of state or private actions which are contemporaneous with the consultation in process (50 CFR 402.02).

2.4.1 Local and Regional Characteristics

The Project is located in the southeastern portion of the Sacramento-San Joaquin Delta, upstream of the Port of Stockton to the north, and the Old River/ Middle River complex to the west (Figure 1), with Project construction sites distributed along the eastern bank of the mainstem San Joaquin River. This freshwater habitat provides critical habitat for CCV steelhead, and sDPS green sturgeon. All of the river channels are tidally influenced in the action area, although reversal of flow may not occur in portions of the action area when the mainstem San Joaquin River flows are elevated. This typically occurs during winter high-flow events on the San Joaquin River. Changes in water surface elevations due to tidal variation occurs in all of the waterways that contain construction element sites.

The land within the action area consist primarily of irrigated fields and orchards traversed by irrigation canals and drainage ditches to the west and northeast of the San Joaquin River, and urban developments within the southern portion of the action area (City of Lathrop and City of River Islands). The canals and ditches seasonally provide water from the Delta via pumps or siphons to the adjoining fields and then provide drainage back to the Delta, using pumps to move water over the levees to the adjoining waterways. Levees protect lands to both the east and west of the San Joaquin River from flooding during high water events. These existing levees were initially built in the late 1800s and are maintained for agricultural purposes by local Reclamation Districts, but are also part of the Federal Flood Control Project authorized by Congress in 1917, and completed in 1960 by the USACE.

2.4.1.1 Water Development

The diversion and storage of natural flows by dams and diversion structures on Central Valley watersheds has depleted stream flows in the tributaries feeding the Delta and altered the natural cycles by which juvenile and adult salmonids and sDPS green sturgeon base their migrations. As much as 60 percent of the natural historical inflow to Central Valley watersheds and the Delta have been diverted for human uses. Depleted flows have contributed to higher temperatures, lower DO levels, and decreased recruitment of gravel and large woody debris (LWD, also referred to as instream woody material or IWM). More uniform flows year round have resulted in diminished natural channel formation, altered foodweb processes, and slower regeneration of riparian vegetation (Mount 1995).

Water withdrawals, for agricultural and municipal purposes have reduced river flows and increased temperatures during the critical summer months, and in some cases, have been of a sufficient magnitude to result in reverse flows in the lower San Joaquin River (Reynolds et al. 1993). Direct relationships exist between water temperature, water flow, and juvenile salmonid survival (Brandes and McLain 2001). Elevated water temperatures in the Sacramento River have limited the survival of young salmon in those waters. Juvenile fall-run survival in the Sacramento River is also directly related with June streamflow and June and July Delta outflow (Dettman et al. 1987).

Water diversions for irrigated agriculture, municipal and industrial use, and managed wetlands are found throughout the Central Valley. Thousands of small and medium-size water diversions exist along the Sacramento River, San Joaquin River, and their tributaries as well as in the maze of Delta waterways surrounding the intensively farmed islands within the legal Delta boundaries. Although efforts have been made in recent years to screen some of these diversions, many remain unscreened. Depending on the size, location, and season of operation, these unscreened diversions entrain and kill many life stages of aquatic species, including juvenile salmonids and green sturgeon. For example, as of 1997, 98.5 percent of the 3,356 diversions included in a Central Valley database were either unscreened or screened insufficiently to prevent fish entrainment (Herren and Kawasaki 2001).

2.4.1.2 Water Conveyance and Flood Control

The development of the water conveyance system in the Delta has resulted in the construction of more than 1,100 miles of armored levees to increase channel flood capacity elevations and flow capacity of the channels (Mount 1995). Levee development in the Central Valley affects spawning habitat, freshwater rearing habitat, freshwater migration corridors, and freshwater riverine and estuarine habitat PBFs. As Mount (1995) indicates, there is an "underlying, fundamental conflict inherent in this channelization." Natural rivers strive to achieve dynamic equilibrium to handle a watershed's supply of discharge and sediment (Mount 1995). The construction of levees disrupts the natural processes of the river, resulting in a multitude of habitat-related effects; including isolation of the watershed's natural floodplain behind the levee from the active river channel and its fluctuating hydrology.

Many of these levees use angular rock (riprap) to armor the bank from erosive forces. The effects of channelization, and riprapping, include the alteration of river hydraulics and riparian vegetative cover along the bank as a result of changes in bank configuration and structural features (Stillwater Sciences 2006). These changes affect the quantity and quality of nearshore habitat for juvenile salmonids and have been thoroughly studied (USFWS 2000, Schmetterling et al. 2001, Garland et al. 2002). Simple slopes protected with rock revetment generally create nearshore hydraulic conditions characterized by greater depths and faster, more homogeneous water velocities than occur along natural banks. Higher water velocities typically inhibit deposition and retention of sediment and woody debris. These changes generally reduce the range of habitat conditions typically found along natural shorelines, especially by eliminating the shallow, slow-velocity river margins used by juvenile fish as refuge and escape from fast currents, deep water, and predators (Stillwater Sciences 2006).

2.4.1.3 Land Use Activities

Since the 1850s, wetlands reclamation for urban and agricultural development has caused the cumulative loss of 79 and 94 percent of the tidal marsh habitat in the Delta downstream and upstream of Chipps Island, respectively (Conomos et al. 1985, Nichols et al. 1986, Wright and Phillips 1988, Goals Project 1999). Prior to 1850, approximately 1400 km^2 of freshwater marsh surrounded the confluence of the Sacramento and San Joaquin Rivers, and another 800 km^2 of saltwater marsh fringed San Francisco Bay's margins. Of the original 2,200 km^2 of tidally influenced marsh, only about 125 km^2 of undiked marsh remains today. Even more extensive losses of wetland marshes occurred in the Sacramento and San Joaquin River basins. Little of the extensive tracts of wetland marshes that existed prior to 1850 along the valley's river systems and within the natural flood basins exist today. Most has been "reclaimed" for agricultural purposes, leaving only small remnant patches. Engineered levees have isolated the rivers from their natural floodplains and have resulted in the loss of their ecological functions.

Dredging of river channels to enhance inland maritime trade and to provide raw material for levee construction has significantly and detrimentally altered the natural hydrology and function of the river systems in the Central Valley. Starting in the mid-1800s, the USACE and other private consortiums began straightening river channels and artificially deepening them to enhance shipping commerce. This has led to declines in the natural meandering of river channels and the formation of pool and bar segments. The deepening of channels beyond their natural depth also has led to a significant alteration in the transport of bedload in the riverine system as well as the local flow velocity in the channel (Mount 1995). The Sacramento Flood Control Project at the turn of the nineteenth century ushered in the start of large scale USACE actions in the Delta and along the rivers of California for reclamation and flood control. The creation of levees and the deep shipping channels reduced the natural tendency of the San Joaquin and Sacramento rivers to create floodplains along their banks with seasonal inundations during the wet winter season and the spring snow melt periods. These annual inundations provided necessary habitat for rearing and foraging of juvenile native fish that evolved with this flooding process. The armored riprapped levee banks and active maintenance actions of Reclamation Districts precluded the establishment of ecologically important riparian vegetation, introduction of valuable LWD/ IWM from these riparian corridors, and the productive intertidal mudflats characteristic of the undisturbed Delta habitat.

Urban stormwater and agricultural runoff may be contaminated with pesticides, oil, grease, heavy metals, poly-aromatic hydrocarbons (PAHs), and other organics and nutrients (Regional Board 1998), which can destroy aquatic life necessary for salmonid survival (NMFS 1996a, b) and are also expected to negatively impact the different green sturgeon life stages also present. Point source (PS) and non-point source (NPS) pollution occurs at almost every point that urbanization activity influences the watershed. Impervious surfaces (i.e., concrete, asphalt, and buildings) reduce water infiltration and increase runoff, thus creating greater flood hazard (NMFS 1996a, b). Flood control and land drainage schemes may increase the flood risk downstream by concentrating runoff. A flashy discharge pattern results in increased bank erosion with subsequent loss of riparian vegetation, undercut banks and stream channel widening. In addition to the PS and NPS inputs from urban runoff, juvenile salmonids and green sturgeon are exposed to increased water temperatures as a result of thermal inputs from municipal, industrial, and agricultural discharges.

2.4.1.4 Water Quality

The water quality of the Delta has been negatively impacted over the last 150 years. Increased water temperatures, decreased dissolved oxygen (DO) levels, and increased turbidity and contaminant loads have degraded the quality of the aquatic habitat for the rearing and migration of salmonids and sDPS green sturgeon. Some common pollutants include effluent from wastewater treatment plants and chemical discharges such as dioxin from San Francisco Bay petroleum refineries (McEwan and Jackson 1996). In addition, agricultural drain water, another possible source of contaminants, can contribute up to 30 percent of the total inflow into the Sacramento River during the low-flow period of a dry year. The Regional Board, in its 1998 Clean Water Act §303(d) list characterized the Delta as an impaired waterbody having elevated levels of chlorpyrifos, dichlorodiphenyltrichlor (i.e. DDT), diazinon, electrical conductivity, Group A pesticides [aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, hexachlorocyclohexanes (including lindane), endosulfan and toxaphene], mercury, low DO, organic enrichment, and unknown toxicities (Regional Board 1998, 2001, California State Water Resources Control Board 2010).

In general, water degradation or contamination can lead to either acute toxicity, resulting in death when concentrations are sufficiently elevated, or more typically, when concentrations are lower, to chronic or sublethal effects that reduce the physical health of the organism, and lessens its survival over an extended period of time. Mortality may become a secondary effect due to compromised physiology or behavioral changes that lessen the organism's ability to carry out its normal activities. For example, increased levels of heavy metals are detrimental to the health of an organism because they interfere with metabolic functions by inhibiting key enzyme activity in metabolic pathways, decrease neurological function, degrade cardiovascular output, and act as mutagens, teratogens or carcinogens in exposed organisms (Rand et al. 1995, Goyer 1996). For listed species, these effects may occur directly to the listed fish or to its prey base, which reduces the forage base available to the listed species.

In the aquatic environment, most anthropogenic chemicals and waste materials, including toxic organic and inorganic chemicals, eventually accumulate in sediment (Ingersoll 1995). Direct exposure to contaminated sediments may cause deleterious effects to listed salmonids and green sturgeon. This may occur if a fish swims through a plume of the resuspended sediments or rests on contaminated substrate and absorbs the toxic compounds through one of several routes: dermal contact, ingestion, or uptake across the gills. Elevated contaminant levels may be found in localized “hot spots” where discharge occurs or where river currents deposit sediment loads. Sediment contaminant levels can thus be significantly higher than the overlying water column concentrations (U.S. Environmental Protection Agency [USEPA] 1994). However, the more likely route of exposure to salmonids or green sturgeon is through the food chain, when the fish feed on organisms that are contaminated with toxic compounds. Prey species become contaminated either by feeding on the detritus associated with the sediments or dwelling in the sediment itself. Therefore, the degree of exposure to the salmonids and green sturgeon depends on their trophic level and the amount of contaminated forage base they consume. Response of salmonids and green sturgeon to contaminated sediments is similar to water borne exposures once the contaminant has entered the body of the fish.

2.4.1.5 Hydrology of the Delta

Substantial changes have occurred in the hydrology of the Central Valley’s watersheds over the past 150 years. Many of these changes are linked to the ongoing actions of the CVP and SWP in their pursuit of water storage and delivery of this water to their contractors.

Prior to the construction of dams on the tributaries surrounding the Central Valley, parts of the valley floor hydrologically functioned as a series of natural reservoirs seasonally filling and draining every year with the cycles of rainfall and snow melt in the surrounding watersheds. These reservoirs delayed and muted the transmission of floodwaters traveling down the length of the Sacramento and San Joaquin rivers. Historically, there were at least six distinct flood basins in the Sacramento Valley. These extensive flood basins created excellent shallow water habitat for fish such as juvenile Chinook salmon, steelhead, and sturgeon to grow and rear before moving downstream into the Delta (The Bay Institute 1998). The magnitude of the seasonal flood pulses were reduced before entering the Delta, but the duration of the elevated flows into the Delta were prolonged for several months, thereby providing extended rearing opportunities for emigrating Chinook salmon, steelhead, and green sturgeon to grow larger and acquire additional nutritional energy stores before entering the main Delta and upper estuarine reaches.

Prior to the construction of dams, there were distinct differences in the natural seasonal flow patterns between the northern Sacramento River watershed and the southern San Joaquin River watershed. Furthermore, the natural unimpaired runoff in the Central Valley watersheds historically showed substantial seasonal and inter-annual variability. Watersheds below 5,000 feet in elevation followed a hydrograph dominated by rainfall events with peak flows occurring in late fall or early winter (northern Sierra Nevada, Cascade Range, and most of the western coastal mountains). Conversely, those watersheds with catchment areas above 5,000 feet, such as the Central and Southern Sierras, had hydrographs dominated by the spring snowmelt runoff period and had their highest flows in the late spring/early summer period. Summertime flows on the valley floor were considerably reduced after the seasonal rain and snowmelt pulses were finished (Figure 14), with base flows supported by the stored groundwater in the surrounding alluvial plains (The Bay Institute 1998). Since the construction of the more than 600 dams in the mountains surrounding the Central Valley, the variability in seasonal and inter-annual runoff has been substantially reduced and the peak flows muted, except in exceptional runoff years. Currently, average winter/spring flows are typically reduced compared to natural conditions, while summer/fall flows have been artificially increased by reservoir releases. Wintertime releases are coordinated for preserving flood control space in the valley's large terminal storage dams, and typically do not reach the levels necessary for bed load transport and reshaping of the river channels below the dams. Summertime flows have been scheduled for meeting water quality goals and consumptive water demands downstream (Figures 15 and 16). Mean outflow from the Sacramento River during the later portion of the 19th century has been reduced from nearly 50 percent of the annual discharge occurring in the period between April and June to only about 20 percent of the total mean annual outflow under current dam operations (The Bay Institute 1998). Currently, the highest mean flows occur in January, February, and March. The San Joaquin River has seen its snowmelt flood peak essentially eliminated, and the total discharge to the valley floor portion of the mainstem greatly reduced during the spring. Only in very wet years is there any marked late spring outflow peak (The Bay Institute 1998).

These changes in the hydrographs of the two main river systems in the Central Valley are also reflected in the inflow and outflow of water to the Delta. The operations of the dams and water transfer operations of the CVP and SWP have reduced the winter and spring flows into the Delta, while artificially maintaining elevated flows in the summer and late fall periods. The Delta has thus become a conveyance apparatus to move water from the Sacramento side of the Delta to the southwestern corner of the Delta where the CVP and SWP pumping facilities are located. Releases of water to the Delta during the normally low flow summer period have had several impacts on Delta ecology and hydrology. Since the projects started transferring water through the Delta, the normal variability in the hydrology of the Delta has diminished. Annual incursions of saline water into the Delta still occur each summer, but have been substantially muted compared to their historical levels by the release of summer water from the reservoirs (Herbold and Moyle 1989, Figures 17 and 18). The Delta has become a stable freshwater body, which is more suitable for introduced and invasive exotic freshwater species of fish, plants, and invertebrates than for the native organisms that evolved in a fluctuating and "unstable" Delta environment.

Furthermore, Delta outflow has been reduced by approximately 14 percent from the pre-dam period (1921-1943) when compared to the modern state and federal water project operations period (1968-1994). When differences in the hydrologic year types are accounted for and the "wet" years are excluded, the comparison between similar year types indicates that outflow has been reduced by 30 to 60 percent (The Bay Institute 1998), with most of this "lost" water going to exports. Currently, the Sacramento River contributes roughly 75-80% of the Delta inflow in most years and the San Joaquin River contributes about 10-15%; the Mokelumne, Cosumnes, and Calaveras rivers, which enter into the eastern side of the Delta, contribute the remainder. The sum of the river contributions flow through the Delta and into Suisun Bay, San Pablo Bay, San Francisco Bay, and eventually empties into the Pacific Ocean. Historical annual Delta inflow between 1945 and 1995 (i.e., the period of modern dam operations) averaged approximately 23 million acre-feet (MAF), with a minimum inflow of approximately 6 MAF in 1977 and a maximum of approximately 70 MAF in 1983 (USACE 2015).

Water movement in the Delta responds to four primary forcing mechanisms: (1) freshwater inflows draining to the ocean; (2) Delta exports and diversions; (3) operation of water control facilities such as dams, export pumps, and flow barriers; and (4) the regular tidal movement of seawater into and out of the Delta. In addition, winds and salinity behavior within the Delta can generate a number of secondary currents that, although of low velocity, can be of considerable significance with respect to transporting contaminants and mixing different sources of water. Changes in flow patterns within the Delta, whether caused by export pumping, winds, atmospheric pressure, flow barriers, tidal variations, inflows, or local diversions, can influence water quality at drinking water intakes (USACE 2015).

2.4.1.6 NMFS Salmon and Steelhead Recovery Plan Action Recommendations

The NMFS Recovery Plan that includes Sacramento River winter-run Chinook salmon, CV Spring-run Chinook salmon and CCV steelhead (NMFS 2014) identifies recovery goals for the Sacramento River and San Joaquin River basin populations that utilize the waterways of the Delta for aspects of their life history. These waterways include the action area for the proposed Project. Recovery efforts focus on addressing several key stressors that are vital to Sacramento River winter-run Chinook salmon, CV spring-run Chinook salmon, and CCV steelhead: (1) Altered natural riverine flows entering the Delta from the Sacramento and San Joaquin River basins affecting adult and juvenile migration and holding; (2) Altered hydrodynamics due to operations of the CVP and SWP export facilities affecting migratory cues of migrating juveniles; (3) Altered riparian and marsh habitats due to levee construction and marshland reclamation efforts; and (4) Increased exposure to non-native predation within the waterways of the Delta.

2.4.1.6.1 Specific Key Stressors in the Delta described in the Recovery Plan

- Altered hydrographs of the Sacramento and San Joaquin rivers entering the Delta due to upstream operations of reservoirs that does not represent the historic natural unimpaired inflow pattern used by fish for attraction and migratory behavioral cues.

- Altered hydrodynamics in the central and southern Delta due to the operations of the SWP and CVP export facilities.

- Loss of natural ecological function in the majority of the Delta landscape due to human activities.

- Limited quantity and quality of rearing and migratory habitat due to human actions related to levee construction.

- Loss of extensive marshland habitat in both fresh and saltwater habitats used for rearing and holding of migrating salmonids due to human activities.
- Unscreened or poorly screened agricultural diversions.
- Increased predation risks to juvenile salmonids from non-native predators.
- Restoration and/or creation of floodplain habitat for juvenile salmonids entering or rearing in the Delta.

Recovery actions identified in the Recovery Plan for the Delta that are relevant to this consultation include: landscape level restoration of ecological functions within the Delta waterways, and restoration of floodplain habitat, which are the subjects of the restoration actions currently being implemented in the south Delta region in concert with the Recovery Plan.

2.4.2 Status of Species and Critical Habitat within the Action Area

2.4.2.1 Status of the Species within the Action Area

The action area functions primarily as a migratory corridor for CV spring-run Chinook salmon from the San Joaquin River Restoration Program's (SJRRP) experimental population, CCV steelhead from the Southern Sierra Nevada Diversity Group, and potentially the sDPS of North American green sturgeon, but it also provides some use as holding and rearing habitat for each of these species as well. Juvenile salmonids may use the area for rearing for several weeks during the winter and spring before migrating to the marine environment. Green sturgeon may use the area for rearing and potentially migration into/ out of the San Joaquin River Basin year-round. Generally, as flows increase in the fall and through the winter, adult salmon, CCV steelhead, and sDPS green sturgeon migrate upstream through the Sacramento and San Joaquin rivers. Juvenile salmonids migrate downstream in the winter and spring, while juvenile green sturgeon have a protracted downstream migration that lasts from summer into winter. Adult CV spring-run migrate through the Delta between January and June (Table 5). Adult CCV steelhead migration typically begins in August, with a peak in September and October for the Sacramento River basin and slightly later for San Joaquin River basin fish, and extends through the winter to as late as May (Table 6). Adult green sturgeon start to migrate upstream to spawning reaches in the Sacramento River basin in February and their migrations can extend into July (Table 7), but may also be found holding in waters of the Sacramento River basin and Delta year-round. Less is known regarding their potential use of the San Joaquin River basin upstream of the Delta, but sturgeon report card information and the observation of a live green sturgeon in the Stanislaus River in October 2017, indicate that there is opportunistic use of this watershed to some degree.

2.4.2.1.1 CV Spring-run Chinook salmon

Currently there are no documented natural populations of CV spring-run in the San Joaquin River basin that would likely occur in the action area. However, there is anecdotal evidence of Chinook salmon occurring in the Stanislaus and Tuolumne Rivers that may represent residual populations of spring-run Chinook salmon or individuals that have strayed from other river basins and use the Stanislaus and Tuolumne rivers for spawning based on their run timing and the presence of fry and juveniles that show traits characteristic of spring-run populations such as hatching dates and seasonal sizes (Franks 2013). Furthermore, the SJRRP goal of re-establishing an experimental population of CV spring-run in the San Joaquin River basin will create the potential that spring-run Chinook salmon will be present in the action area over the Project's lifetime due to the continued presence of the constructed floodplain area into the future. Presence of adult or juvenile CV spring-run in the action area during the proposed construction window of July 1 through November 1 over the two year construction period is unlikely based on the following life history characteristics.

There are no spawning areas in the action area that could be used by adult spring-run, therefore the potential that eggs would be present in the action area is nonexistent. Likewise, the potential for alevins to be present in the action area is also unlikely, since only extreme precipitation events in the fall and early winter resulting in high river flows in the San Joaquin River basin could flush alevins out of their natal tributaries into the action area. Fry and parr are more likely to be present in the action area in response to high river flows due to the timing of winter storms and the progressive maturation of the fish. This period would be from approximately November through March. By April, juvenile spring-run are reaching the size that smoltification occurs, and the majority of smolts would be moving downriver to enter the Delta on their emigration to the ocean. Spring-run smolt outmigration is essentially over by mid-May with only a few late fish emigrating in early June. There is the potential that some juvenile spring-run will remain in the tributaries through the summer and outmigrate the following fall and winter as yearlings, but until the experimental population has had time to establish itself, this behavior is uncertain to occur (Table 5). Adult CV spring-run are expected to be migrating upstream through the action area from January to June with a peak presence from February to April (Table 5). Adult migration is also likely to be strongly influenced by the flow levels in the San Joaquin River basin that provides access to the upstream holding and spawning areas. The broodstock for the spring-run experimental population came from the Sacramento River basin (Feather River Fish Hatchery spring-run Chinook salmon) and are expected to exhibit similar migration timing behavior for both adult and juvenile life stages in the San Joaquin River basin.

The proposed construction period for the Project's actions on the mainstem San Joaquin in the action area is from July 1 through November 1. This will not overlap with the adult CV spring-run Chinook salmon migration period in the San Joaquin River basin (i.e., the months of January through June). The construction window will also avoid overlapping with juvenile CV spring-run Chinook salmon emigration during late winter and spring. However, the long-term operations of the Project's setback levee and constructed floodplain will overlap with both adult migration upstream and juvenile migration downstream every year.

2.4.2.1.2 CCV Steelhead

Small, but persistent populations of CCV steelhead are present in the Calaveras River and San Joaquin River basins and are part of the Southern Sierra Nevada Diversity Group. Both adults and smolts are detected by monitoring efforts in these basins indicating spawning is occurring in the basin's tributaries. There are no spawning areas in the action area that could be used by adult CCV steelhead; therefore the potential that eggs would be present in the action area is nonexistent. All adult CCV steelhead originating in the San Joaquin River basin will pass through the action area to reach their spawning grounds in the Stanislaus, Tuolumne, and Merced rivers, and the tailwater section of the San Joaquin River below Friant Dam, and return to the ocean following spawning through these same waterways. Some adults may access the San Joaquin River basin through the south Delta waterways leading to the Head of Old River near Lathrop, and may return to the ocean via this route too, but most fish are believed to use the mainstem of the San Joaquin River as their migratory route. CCV steelhead smolts leaving the San Joaquin River basin during their emigration pass through the action area. Some fish will use the Old River corridor while others will remain in the mainstem of the river, particularly if a fish barrier is installed at the Head of Old River during their emigration period. The waterways in the action area are expected to be used primarily as migration corridors for adult steelhead and emigrating steelhead smolts, but may also provide some rearing benefits to the emigrating smolts.

CCV steelhead smolts are expected to appear in the action area waterways as early as January, based on observations in tributary monitoring studies on the Stanislaus River, but in very low numbers. The peak emigration in the lower San Joaquin, as determined by the Mossdale trawls near the Head of Old River, occurs from April to May, but with presence of fish typically extending from late February to late June.

Adult CCV steelhead are expected to start moving upstream through the action area into the lower San Joaquin River as early as September, with the peak migration period occurring later in the fall during the November through January period, based on Stanislaus River fish weir counts. Adult CCV steelhead will continue to migrate upriver through March, with post spawn fish, "kelts", moving downstream potentially through spring and early summer, although most are expected to move back downstream earlier than later (Table 6).

The proposed construction period for the Project's actions on the mainstem San Joaquin in the action area is from July 1 through November 1. This will overlap with the adult CCV steelhead migration period in the San Joaquin River basin (i.e., the months of September and October) but will avoid the peak of spawning migration from November through January. However, the long-term operations of the Project's setback levee and constructed floodplain will overlap with both adult migration upstream, and juvenile migration downstream every year.

2.4.2.1.3 Southern DPS of North American Green Sturgeon

Adult green sturgeon begin to enter the Sacramento – San Joaquin Delta in late February and early March during the initiation of their upstream spawning run (Moyle et al. 1995, Heublein et al. 2009). The peak of adult entrance into the Delta appears to occur in late February through early April, with fish arriving upstream of the Glen-Colusa Irrigation District's water diversion on the upper Sacramento River in April and May to access known spawning areas (Moyle 2002). Adults continue to enter the Delta until early summer (June-July) as they move upriver to spawn in the upper Sacramento River basin. It is also possible that some adult green sturgeon will be moving back downstream as early as April and May through the Delta, either as early post-spawners or as unsuccessful spawners. The majority of post-spawn adult green sturgeon will move down river to the Delta either in the summer or during the fall. Fish that over-summer in the upper Sacramento will move downstream when the river water cools and rain events increase the river's flow and either hold in the Delta or migrate to the ocean. Data on green sturgeon distribution is extremely limited and out-migration appears to be variable occurring at different times of year. Seven years of recreational fishing catch data for adult green sturgeon (CDFW sturgeon fishing report cards) show that they are present in the Delta during all months of the year (Figure 19). Although the majority of green sturgeon are expected to be found along the Sacramento River corridor and within the western Delta, observations of green sturgeon occur in the San Joaquin River and upstream of the action area based on the information provided in the

CDFW sturgeon fishing report cards. Presence of fish occurs during all seasons of the year, but primarily from fall through spring. Few fish are caught during the summer period.

Juvenile green sturgeon migrate to the sea when they are 1 to 4 years old (Moyle et al. 1995). According to Radtke (1966), juveniles were collected year round in the Delta during a 1-year study in 1963-1964. The DJFMP rarely collected juvenile green sturgeon at the seine and trawl monitoring sites. From 1981 to 2012, 7,200 juvenile green sturgeon were reported at the State and Federal export facilities (Figure 20), which indicates a higher presence of juvenile green sturgeon during the spring and summer months in the south Delta where the export facilities are located. Based on the above information, adult and juvenile green sturgeon were determined to be present in the Delta year-round (Table 7).

2.4.2.2 Status of Critical Habitat within the Action Area

The PBFs for steelhead critical habitat within the action area include freshwater rearing habitat and freshwater migration corridors. Estuarine areas occur farther downstream where mixing occurs and salinity is greater than 0.5 ppt. The features of the PBFs included in these different sites essential to the conservation of the CCV steelhead DPS include the following: sufficient water quantity and floodplain connectivity to form and maintain physical habitat conditions necessary for salmonid development and mobility, sufficient water quality, food and nutrients sources, natural cover and shelter, migration routes free from obstructions, no excessive predation, holding areas for juveniles and adults, and shallow water areas and wetlands. Habitat within the action area is primarily utilized for freshwater rearing and migration by CCV steelhead smolts and for adult freshwater migration. No spawning of CCV steelhead occurs within the action area.

In regards to the designated critical habitat for the sDPS of North American green sturgeon, the action area includes PBFs which provide: adequate food resources for all life stages utilizing the Delta; water flows sufficient to allow adults, sub-adults, and juveniles to orient to flows for migration and normal behavioral responses; water quality sufficient to allow normal physiological and behavioral responses; unobstructed migratory corridors for all life stages utilizing the Delta; a broad spectrum of water depths to satisfy the needs of the different life stages present in the Delta and estuary; and sediment with sufficiently low contaminant burdens to allow for normal physiological and behavioral responses to the environment.

The general condition and function of the aquatic habitat has already been described in the *Rangewide Status of the Species and Critical Habitat* section of this Opinion. The substantial degradation over time of several of the PBFs has diminished the function and condition of the freshwater rearing and migration habitats in the action area.

Even though the habitat has been substantially altered and its quality diminished through years of human actions, its conservation value remains high for the CCV steelhead DPS and the sDPS of North American green sturgeon. All juvenile CCV steelhead smolts originating in the San Joaquin River basin will likely pass downstream through the action area within the San Joaquin River mainstem channel, particularly if there is a fish barrier at the Head of Old River to prevent smolt entrance into that route. Some steelhead smolts may enter the Old River migratory pathway at the Head of Old River junction, or enter Paradise Cut under high flows. Likewise, adults migrating upstream to spawn are likely to pass through the action area within the main stem of the San Joaquin River to reach their upstream spawning areas in the San Joaquin River basin. Therefore, it is of critical importance to the long-term viability of the CCV steelhead to maintain a functional migratory corridor and freshwater rearing habitat through the action area to sustain the Southern Sierra Nevada Diversity Group, and provide the necessary spatial diversity to achieve recovery.

Due to a deficit of monitoring data directed at this species, an unknown fraction of the sDPS green sturgeon population utilizes the middle and upper San Joaquin River reaches within the Delta, and even less is known about utilization of the San Joaquin River upstream of the Delta. However, designated critical habitat occurs in the action area and includes the San Joaquin River upstream to the limits of the legal Delta (Vernalis) on the San Joaquin River. Preservation of the functionality of the PBFs within this region is important to the long term viability of the sDPS green sturgeon population by providing suitable habitat for the rearing of juveniles, and the foraging and migratory movements of adults.

2.5 Effects of the Action

Under the ESA, "effects of the action" means the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action, that will be added to the environmental baseline (50 CFR 402.02). Indirect effects are those that are caused by the proposed action and are later in time, but still are reasonably certain to occur.

To evaluate the effects of the Project's levee repairs, NMFS examined the effects of the action. We analyzed construction-related impacts and the fish response to habitat modifications from the setback levee and the newly created floodplain. We also reviewed and considered RD 17's conservation measures taken during the repairs.

Our assessment considers the nature, duration, and extent of the action relative to the rearing, and migration timing, behavior, and habitat requirements of all life stages of federally listed fish in the action area. Effects of the levee repair on aquatic resources included both short- and long-term impacts. Short-term impacts include the impacts of construction during the repair. Long-term impacts include the permanent physical alteration of the river bank and riparian vegetation, as well as the construction of the setback levee and associated floodplain, which will last for many years.

Adverse effects can include any impact that reduces the quality or quantity of critical habitat, and may include direct or indirect physical, chemical, or biological alteration of the waters or substrate and loss of (or injury to) benthic organisms, prey species and their habitat, and other ecosystem components. In addition, adverse effects can include any direct or indirect impact to an individual fish that results in take. "Take" is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. "Harm" is further defined by regulation to include significant habitat modification or degradation that actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including breeding, spawning, rearing, migrating, feeding, or sheltering (50 CFR 222.102). The proposed actions include minimal waterside levee alterations (levee breech) and is dominated by bank stabilization measures on the upland portions of the levee above the ordinary high tide elevation, including the levee crown and landside portions of the levees that may impact NMFS-listed species and critical habitat.

Construction activities may increase the level of ambient noise and vibrations in the surrounding aquatic environment, increase turbidity and suspended sediment in adjacent waterways from erosion and airborne sources, and increased night time illumination of the river channel, all of which may disrupt feeding or temporarily displace fish from preferred habitat or impair normal behavior. Some of these effects may occur at a distance from the construction activities because noise and sediment may be propagated away from their point of origin in both an upstream and downstream direction from the construction sites. Substantial increases in suspended sediment could temporarily bury substrates and submerged aquatic vegetation that supports invertebrates for feeding juvenile fish.

The approach used for this analysis was to identify which ESA-listed species would be likely to be present in the action area from July 1 through October 31 (November 1) during construction activities (Table 8). NMFS conducted a review of nearby CDFW and USFWS monitoring locations, run timing, and fish salvage data to determine the likelihood of ESA-listed fish presence (Tables 5-7). Adult salmonids typically migrate through the Delta within a few days. Juvenile Chinook salmon spend from 3 days to 3 months rearing and migrating through the Delta to the mouth of San Francisco Bay (Brandes and McLain 2001, MacFarlane and Norton 2002).

Table 8: Presence of ESA-listed species in the action area during construction.

Month								
	July		August		September		October	
Life Stage								
Species	Adult	Juvenile	Adult	Juvenile	Adult	Juvenile	Adult	Juvenile
CV Spring-run	No	No	No	No	No	No	No	No
CCV Steelhead	No	No	No	No	Yes (Low[a])	Yes (Very Low[b])	Yes (Medium[a])	Yes (Very Low[b])
sDPS Green Sturgeon	Year-round		Year-round		Year-round		Year-round	

[a] Based on the data from the Stanislaus Fish Weir, adult CCV steelhead begin to migrate through the lower San Joaquin River region starting in September, and increasing to higher levels in October.
[b] Based on the DJFMP Sacramento trawl and Chipps Island trawl data, very low levels of juvenile steelhead have been observed in July, September, and October in the Delta region. Fall pulse flows on the San Joaquin River tributaries and fall storms in the San Joaquin River basin may stimulate out migration of steelhead smolts from the San Joaquin River Basin due to elevated flows similar to the emigration behavior observed in Sacramento River basin fish.

The levee repairs will also contribute to the continued confinement of the riverine system that in turn negatively impacts listed fish species and their designated critical habitat. This analysis also evaluates the long-term impacts of the levee repair on fish species and their critical habitat. Presence of CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon in the action area is assumed to occur during their migratory and rearing behaviors that correspond to their presence in the Delta as described in the baseline status section for each listed species.

2.5.1 Construction Related Effects

NMFS expects that adult CCV steelhead as well as juvenile and adult green sturgeon are likely to be present in the action area during the construction actions, although in low numbers. There is a very low probability that juvenile CCV steelhead may be present during the work-window. It is not expected that there is any potential for the presence of CV spring-run at any of the repair sites during the construction window for the Project. No spawning habitat for CV spring-run Chinook salmon, CCV steelhead, or green sturgeon is present in the action area, therefore no adverse effects to spawning adults or incubating eggs are expected.

2.5.1.1 Noise Related Effects

The repair and rehabilitation of the multiple levee elements described in the Project will necessitate the use of heavy construction equipment to transport soils, excavate and grade chimney drains and seepage berms, and excavate trenches or drill holes to create slurry cutoff walls. This equipment will include vehicles such as: dump trucks, front loaders, bulldozers, motor graders, earth compactors, water tank trucks, excavators, and crane mounted augers and drills (deep slurry wall construction). Vehicles are expected to use both patrol roads on existing levee crowns or haul roads on the landside of the levees to gain access to construction locations for each of the Project's elements. Active construction will be carried out on the landside of the existing levees (chimney drains, seepage berms), and upon the levee crown and landside slope to modify the geometry of the existing levee prism at each Project element to conform to USACE specifications for crown width and landside levee slope grade. In addition, the Project elements requiring open trenching to construct shallow slurry cutoff walls will require degradation of the levee prism to approximately 30-50 percent of the levee height. The degradation of the levee will start at the waterside edge of the levee crown, with soil excavated to final construction elevation with a 1:1 slope. These actions will require considerable construction activity at these locations. Those Project elements that require deep slurry cutoff walls will not require degradation of the levee crown, but rather have a special crane mounted auger/drill rig boring into the levee prism to a depth of 80 to 100 feet or more to loosen and mix the soil. Then, as the auger/drill rig is withdrawn, cement or bentonite slurry is injected and mixed with the loosened soil to form the impervious slurry wall.

Sounds can enter water through a variety of pathways. Sounds may enter from the air, although with strong attenuation of the signal, at the surface of the water (for example shipping and waves), and within the water column itself. In addition, sound may be generated within the substrate, especially by human activities such as pile driving, dredging, and the passage of vehicular traffic along adjacent highways and bridges (Popper and Hawkins 2018). Construction activities such as excavation, grading, and construction of slurry cut-off walls, as well as vehicular traffic of heavy construction equipment is expected to create vibrations and airborne sounds adjacent to the San Joaquin River at all Project element levee locations. These vibrations and sounds are expected to alter the soundscape of the aquatic environment in the adjacent river. Vibrations from construction activities and vehicular traffic will create compression waves in the soil of the levee prism that will rapidly propagate through this dense medium to the adjacent river channel. When the compression wave meets the interface between the soil and the overlying water body, a wave is created at the interface. This wave creates both a sound pressure wave that radiates away from the soil-water boundary as well as a localized acceleration of particles in the water (particle motion) (Popper and Hawkins 2018). Fish are able to detect both the sound pressure wave as well as the particle motion (Popper and Hastings 2009, Radford et al. 2012, Hawkins, Pembroke, and Popper 2015, and Popper and Hawkins 2018). The propagation of sound in the shallow-water environment of the San Joaquin River channel is likely to be highly complex, reflecting off of the water surface, from the substrate, discontinuities in the water, and any immersed objects.

Direct effects upon listed fish in the San Joaquin River are associated with the aforementioned construction work, and will produce the underwater sound pressure waves, and particle motion described above, thereby temporarily altering in-river conditions. Noise generated by construction activities are expected to take two main forms: sharp, transient spikes in noise caused typically by metal (such as an excavator bucket or bulldozer blade) striking a hard object, or by rocks falling on top of each other when armoring the levee face with stone riprap (levee breech location); and lower frequency or infrasonic sound caused by the movement of construction equipment and their earthmoving and excavation activities. Transient noise spikes that occur in the upland areas of the construction sites will be much lower in magnitude when they reach the water, losing energy as the sound travels through the soil and through the soil/water interface into the active channel. There is a very low potential for direct injury or mortality due to the short duration of transient spikes and the nature of their wave rise form. Transient noise is more likely to result in behavioral reactions in exposed fish, such as a startle response. Low frequency or infrasonic noise is also likely to have a low potential for causing direct injury to exposed fish. It is more likely to cause behavioral responses, such as avoidance or movement away from the noise source, or a delay in migration past the location of the noise source.

Only those fish that are holding adjacent to or migrating past the levee repair site will be directly exposed or affected by construction related noise. Those fish that are exposed to the effects of construction activities will encounter short-term construction-related noise (several hours during the day) for most of the Project element locations. Most of the Project elements are likely to have construction work occurring during the day with a period of relative quiet during the night. However, some locations (elements Va and VI1a.1) are described as having construction activities continuing over a 24 hour period, 7 days a week, until the construction activity is completed. These two sites are associated with the construction of 9,500 feet of continuous cutoff walls using the open-cut method of slurry cutoff wall construction. Although direct injury or harm is unlikely, behavioral avoidance may cause injury or harm by increasing the susceptibility of some individuals to predation by temporarily disrupting normal sheltering behaviors. These changes may also impair feeding behaviors, which in turn impact their ability to grow and survive. Fish, especially adults, often respond to construction activities by quickly swimming away from the construction sites, resulting in the majority escaping direct physical injury. Avoidance of the reach of river with construction related noise may prolong or inhibit migratory behavior through that reach. This is considered a form of harassment that results in take of the exposed fish.

Based on the timing of the construction actions, only adult steelhead and adult and juvenile green sturgeon are likely to be present in the action area during the construction window (July 1 through November 1) and therefore be exposed to construction related noise. Based on the observations of steelhead passage at the Stanislaus fish weir, adult steelhead begin to be observed moving into San Joaquin River basin tributaries in September, but do not arrive in any substantial numbers until after the middle of September to early October. By mid-October and through the end December, the frequency of adult steelhead observations at the Stanislaus River weir increases. Observation of adult steelhead passage into the Stanislaus River is artificially truncated in most years by the removal of the fish counting weir on the Stanislaus River by the end of December or early January. There is a very low probability that juvenile CCV steelhead may be present in the action area during the construction window and thus be exposed to construction related noise. Presence of juvenile steelhead would likely only occur if significant increases in river flows occur either through dam releases or strong fall storms. Since both juvenile and adult green sturgeon are observed year–round in the Delta, it is assumed that these life stages of green sturgeon will be present in the action area during the entire construction window. No life stages of CV spring-run Chinook salmon will be directly affected by construction associated noise during the construction work window since they are not present in the action area during this period of time.

2.5.1.2 Contaminant Related Effects

Toxic substances used at construction sites, including gasoline, lubricants, and other petroleum-based products, could enter the waterway as a result of spills or leakage from machinery and injure listed salmonids and green sturgeon exposed to these substances. Petroleum products also tend to form oily films on the water surface that can reduce the exchange of oxygen between the atmosphere and the water, thus reducing the concentration of dissolved oxygen available to aquatic organisms. The exposure to these substances can kill fish directly in high enough concentrations through acute toxicity or suffocation from lack of oxygen. These chemicals may also kill the prey of listed fish species, reducing their ability to feed and therefore grow and survive. However, due to adherence to BMPs that dictate the use, containment, and cleanup of contaminants, the use of toxic substances within the action area is unlikely to negatively impact listed fish species.

Furthermore, based on the timing of the construction window, only adult CCV steelhead, and adult and juvenile green sturgeon are likely to be present during the period of construction activities that might cause the release of contaminants. As stated previously, it is very unlikely that juvenile steelhead would be present during the construction window. It is also not likely that any life stages of CV spring-run will be present during the construction window and thus potentially be exposed to any spill of contaminants related to the construction of the Project.

2.5.1.3 Turbidity Related Effects

Excavation of the levee crown and landside levee face will create conditions that can increase the amount of local water turbidity through erosion of exposed soils through precipitation runoff and by soils dislodged by winds during construction being carried into adjacent San Joaquin River waters. Responses of salmonids to elevated levels of suspended sediments often fall into three major categories: physiological effects, behavioral effects, and habitat effects (Bash et al. 2001). Salmonids exposed to slight to moderate increases in turbidity exhibited avoidance, loss of station in the stream, reduced feeding rates and reduced use of overhead cover. Reaction distances of rainbow trout to prey were reduced with increases of turbidity of only 15 NTUs over an ambient level of 4 to 6 NTUs in experimental stream channels (Barret et al. 1992). Increased turbidity, used as an indicator of increased suspended sediments, also is correlated with a decline in primary productivity, a decline in the abundance of periphyton, and reductions in the abundance and diversity of invertebrate fauna in the affected area (Lloyd 1987, Newcombe and MacDonald 1991). These impacts to the aquatic environment decrease the availability of food resources for salmonids and sturgeon through trophic energy transfers from the lowest trophic levels (i.e., phytoplankton and periphyton) through intermediate levels (e.g., invertebrates) to higher trophic levels (i.e., salmonids and sturgeon).

Based on the timing of construction, it is unlikely that any other listed salmonid other than adult steelhead, will be present during the construction window. It is expected that any adult steelhead will move away from any turbidity plume and seek waters that are more acceptable to their preferences. It is very unlikely that any juvenile steelhead will be present during the construction window and thus be exposed to construction related turbidity. Furthermore, NMFS anticipates adherence to the BMPs described above in the Proposed Action section will greatly minimize the risk of injury or death caused by increases in turbidity. The Project description indicates that a

SWPPP will be developed and implemented for the Project that identifies specific BMPs to avoid and minimize Project effects on water quality, and that the Project will have all appropriate NPDES permits in place before construction starts. Thus, short term turbidity increases associated with construction will be minimized by the implementation of these permits and plans.

It is expected that both juvenile and adult green sturgeon will be present during the construction window. Increases in turbidity and sedimentation events are not expected to affect visual feeding success of green sturgeon, as they are not believed to utilize visual cues (Sillman et al. 2005). Green sturgeon, which can occupy waters containing variable levels of suspended sediment and thus turbidity, are not expected to be impacted by the increases in the turbidity levels anticipated from the proposed project directly, but suffer secondary effects due to impacts on the habitat (i.e., invertebrate forage base populations).

2.5.1.4 Nighttime Worksite Illumination

In order to continue construction work to install the cutoff walls at elements Va and VIa.1 at night, the work site areas must be illuminated by artificial light. This will require that lights and potentially power generators be used during the nighttime construction hours. Lights will be located along the crown of the levee where the trenching and slurry wall work is occurring. The Project description indicates that one of the avoidance and minimization measures to be used for listed fish is to shield any lighting used for nighttime work and to direct the lights away from the waterside face of the levee. The intent is to reduce or avoid any direct illumination of the adjacent river waters during the night. Although direct lighting of the adjacent waterway will be avoided, illumination of the work areas will still create elevated light levels over the river channel due to backscatter from dust or moisture in the air.

Natural conditions would normally have low light levels during the nocturnal period, with light provided only by the moon or by starlight. Due to the increase in artificial lights related to modern civilization, the nighttime environment has been transformed, and true darkness at night is rare. Even in relatively isolated areas with little development or human populations, the night time sky has increased illumination due to “light pollution” from distant urban centers that will brighten the horizon. Light pollution is the degradation of the photic habitat by artificial light and impacts organisms when they are exposed to light in the wrong place, at the wrong time, or at the wrong intensity.

Alterations in the level of light at night has been shown to alter the circadian rhythms of European perch (*Perca fluviatilis*) by altering the production of the hormone melatonin (Brüning et al. 2015). Melatonin is typically produced at night by the pineal organ. Melatonin production is suppressed during the day due to increased light. The pineal organ in fish is light sensitive and directly processes photoperiodic information for cells and organs. Melatonin production was inhibited by light levels as low as 1 lux (approximately equivalent to the light of a full moon). Impairment of melatonin production can eventually affect sexual maturation and gonadal development in multiple species of fish. Increased illumination at night has also been shown to alter the behavior of juvenile salmonids (Tabor and Bell 2015, Tabor et al. 2017). Experimentally manipulating illumination along the shoreline of lakes in Washington increased the abundance of juvenile salmon, including Chinook salmon, Coho salmon (*O. kisutch*), and sockeye salmon (*O. nerka*) in the nearshore areas illuminated by artificial light sources compared to areas of no additional lighting. Other ecological effects of light pollution, besides changes to physiology, include disruption of predator-prey relationships. Yurk and Trites (2000) observed that harbor seals (*Phoca vitulina*) congregated to feed on juvenile salmon in illuminated areas below bridges as the salmon migrated downstream. Seal predation on the juvenile salmon was reduced when the lights were turned off. Tabor et al. (2017) observed avian predators feeding on subyearling salmon in their illuminated study areas at night.

NMFS anticipates that the increased nighttime illumination provided by the work lights at the two construction locations (Va and VIa.1) will negatively impact fish present in those river reaches. Impacts may be either physiological (i.e., altered melatonin levels affecting circadian rhythms) or behavioral (alteration of migratory or movement behavior). Nighttime illumination may also enhance the risk of predation. The longer the exposure to the increased nighttime illumination, the higher the risk of potential harm.

Based on the timing of the construction window, only adult CCV steelhead, and adult and juvenile green sturgeon are likely to be present during the period of construction activities that would increase nighttime illumination. As stated previously, it is very unlikely that juvenile steelhead would be present during the construction window. It is not likely that any life stages of CV spring-run will be present during the construction window and thus potentially be exposed to increased nighttime illumination related to the construction of the Project.

2.5.1.5 Perpetuation of Levee presence

The repair of the levees will perpetuate the current habitat conditions in the southern Delta. The construction of levees to protect against flooding has significantly altered the environment of the southern Delta. Levees replaced the naturally occurring shallow water habitat that existed along the banks of rivers and sloughs in the Delta and the spectrum of complex habitats they provided. Shallow water habitats had a broad range of depths and water velocities present due to the presence of shallow water and riparian vegetation, fallen trees and woody materials (i.e., IWM) that existed on their banks, and the ability of the river to migrate across the floodplain to create additional complexity in the geometry of the river's cross section. Native fish species, including listed salmonids and green sturgeon, evolved under these environmental conditions. In addition, naturally flowing rivers were able to construct riverside benches and naturally formed levees during flood events. These benches could be up to 20 feet high and extended for considerable distances inland creating suitable conditions for the establishment and successional development of structurally diverse riparian vegetation communities (The Bay Institute 1998).

Rock rip-rapping, which is designed to protect the levee faces from erosion, will have deleterious effects on the functioning of the riverine process (USFWS 2000). The intent of riprap is to stabilize stream channels and limit natural fluvial processes. The reduction of the erosion and consequent deposition cycle, naturally inherent to all alluvial channels, eliminates a channel's ability to maintain bedforms for salmonid habitat and impairs the ability for a stream to be maintained in a dynamic steady state. This alteration of the aquatic ecosystem has diverse deleterious effects on aquatic communities, ranging from carbon cycling to altering salmonid population structures and fish assemblages (Schmetterling et al. 2001). Riprap does not provide the intricate habitat requirements for multiple age classes or species similar to natural banks, or banks that include IWM (Peters et al. 1998).

Loss of IWM negatively impacts salmonids through multiple phases of their life history. Schaffter et al. (1983) showed that juvenile Chinook salmon densities along riprapped banks are one third that of natural banks with the presence of fallen trees and their root balls in the water. They concluded that traditional riprap methods of protection will likely cause decreases in the salmon numbers in the Sacramento River basin. USFWS (2000) reported that in studies conducted in the Sacramento River near the Butte Basin, the highest number of juvenile Chinook salmon were associated with the nearshore areas with woody material, sloping banks, and moderate velocities. Juvenile Chinook salmon catches (measured as catch per unit effort or "CPU") were consistently lowest at riprapped sites and highest at natural bank sites (areas with overhead cover and instream woody cover) and intermediate in areas where experimental mitigation studies placed artificial IWM bundles and root balls. USFWS (2000) reported that additional studies conducted between Chico Landing and Red Bluff on the Sacramento River confirmed the low value of riprapped banks, the high value of natural banks with varying degrees of instream and overhead woody cover, and the intermediate value of mitigated sites.

In large mainstem streams and rivers such as the Sacramento and San Joaquin rivers, the primary benefit of IWM is to the channel margins. The woody materials act to deflect and break up stream flow, creating small eddies, pools, undercut banks, variability in channel depth, and back water areas conducive to rearing and growth of salmonids (Murphy and Meehan 1991, Bisson et al. 1987). Sediment that is trapped by the woody material and stored along the channel margins contributes to the hydraulic and biologic complexity of the stream reach, particularly where organically rich materials are present (Bisson et al. 1987). These storage areas create new habitat complexity by trapping inorganic material that creates bars and holes and organic materials that contribute energy and carbon to the local food web of the stream reach (Murphy and Meehan 1991, Bisson et al. 1987). These breaks in the river flow also create beneficial holding areas with plentiful food resources and the conditions where salmonids can hold with minimal energy expenditure and feed while rearing. These areas are also beneficial to a wide range of other species native to the system. Such refuges are critically important to the lower river reaches where levee construction and riprapping have disconnected the rivers from the adjoining floodplain where these refuges and rearing habitats formerly existed.

Riprapping affects the stability of IWM along the river channel margin. Stable wood retention is important for creating and maintaining good fish habitat (Bisson et al. 1987). Whole trees and their root balls are more important for long-term stability than smaller fragments, as they tend to stay in place for long periods of time. These large pieces of wood may remain in place for decades and in the process trap additional IWM, thus adding to the structure. The longevity of large woody debris however may mask changes in the input of woody materials to the river. Since these large pieces of wood would normally be slow to decay, a decline in the woody material input may be masked. Riprapping of the San Joaquin and Sacramento rivers and Delta waterway banks prevents the normal input of upstream woody materials through erosion. The smooth hydraulic roughness along the riprapped banks prevents pieces of woody materials from becoming anchored and remaining in place. The woody materials are transported downstream, but the riprapping of the lower river and Delta waterway banks further limit these pieces from becoming lodged on the banks and the woody material is lost to the system. There is a continuing reduction of IWM input from upstream and local waterways, so that the presence of large pieces of IWM in the Delta is becoming exceedingly rare. Existing pieces that are removed or break apart from decay are not being replenished from upstream.

Like the studies upriver in the mainstem Sacramento River, salmonids in the Delta are associated with natural banks and IWM cover where there is sandy or muddy substrates and shallow water shorelines (McLain and Castillo 2009). Areas with riprap and a lack of cover tended to be dominated by non-native predators and these riprapped shorelines had lower densities of salmonids present. Other studies have shown this trend for non-natives, in particular piscivorous fish that prey on salmonids, (Nobriga et al. 2005, Brown and May 2006, Brown and Michniuk 2007, and Grimaldo et al. 2012). It is unclear whether the low density of salmonids in riprapped areas is caused by salmon avoiding these areas volitionally or whether they are very vulnerable to predation from non-native predators with a resulting high predation loss (Schmetterling et al. 2001, McLain and Castillo 2009).

2.5.1.6 Setback Levee

The Project proposes to construct a setback levee at element IVc and create up to 11.1 acres of riparian vegetation between the setback levee and the San Joaquin River. This will include approximately 6.1 acres of restored riparian scrub habitat between the landside of the existing levee along the San Joaquin River and the waterside toe of the newly constructed setback levee, and between the river and the waterside toe of the existing levee. In addition, approximately 5 acres of Great Valley oak woodland/ upland refugia habitat along the existing levee prism will be created. The elevation of the proposed floodplain portion of this newly constructed area is still under review. Current proposals range from an elevation of 8 feet NAVD88 to 14 feet NAVD88 with a return interval of 2 to 6 years respectively for inundation of the levee breech invert (Table 2). Based on current design, not all of the interior floodplain will be inundated once the high river flows inundate the levee breech. The Project description states that 1-2 acres of the interior floodplain will be set to 14 feet NAVD88 or below, which will inundate at least every 6 years on average based on historical hydrology. More frequent inundation of this area could occur if the elevation is set lower than 14 feet NAVD88.

Over a much longer time period, inundation may become more frequent due to sea level rise, resulting in tides in the Delta reaching higher water surface elevations than are currently seen. Although the elevation of the setback levee and created floodplain is much higher than sea level and above any predicted increase in sea level rise, the effects of tides in the Delta are manifested by increasing the level of the river surface elevations as the flood tides push back upstream against the river flow. There is typically a 2 to 3 foot change in water surface elevation between low tide and high tide in the action area with a slightly greater range during spring tides. Over the next century, predicted sea level rise in the northern Pacific ranges from 0.5 meters to 1 meter (~ 20 to 40 inches) and thus could potentially raise the water surface elevation of the San Joaquin River in the action area due to tidal actions an equivalent amount. This has the potential to increase the frequency of the inundation of the breeched levee invert due to typical tides increasing the water surface elevation an additional 20 to 40 inches during high river flows.

Annual inundation of seasonal floodplains enhances the productivity and biotic interactions in river-floodplain systems as proposed by Junk et al. (1989) in their flood pulse concept. Floodplains provide higher biotic diversity, increasing the production of fish and invertebrates, while increasing habitat diversity and enhancing nutrient flow and cycling between terrestrial and aquatic habitats. Inundation of floodplains has been shown to be beneficial to Central Valley native fish including Chinook salmon (Sommer et al. 2001a, b; Sommer et al. 2005, Moyle et al. 2007, Jeffres et al. 2008; Takata et al. 2017). These studies reported that the growth of juvenile Chinook salmon on the inundated floodplains was enhanced and fish were typically larger than fish that remained in the mainstem river channel. In the Yolo Bypass, the duration of floodplain inundation is positively associated with hatchery juvenile Chinook salmon residing longer on the floodplain and growing to larger sizes. Wild juvenile Chinook salmon also grew larger and emigrated later (Takata et al. 2017). Jeffres et al. (2008) found similar results on the Cosumnes River floodplain, with significant differences in growth rates between salmon reared on the floodplain and those reared in river enclosures. Salmon reared in seasonally inundated habitats with annual terrestrial vegetation experienced higher growth rates than those fish reared in perennial ponds on the floodplain.

Rearing on floodplains can also increase risks such as stranding or predation (Sommer et al. 2005, Moyle et al. 2007, Takata et al. 2017). Floodplain habitats are typically spatially and temporally variable, with the period and extent of inundation changing from year to year and even month to month during the wet winters in California. However, Chinook salmon appear to successfully avoid most stranding and predation issues. Although some fish may become stranded, particularly in manmade structures such as the concrete scour ponds adjacent to the Fremont and Sacramento weirs at the upstream end of the Yolo Bypass (Sommer et al. 2005), most fish appeared to successfully negotiate leaving the floodplains as the water levels receded (Sommer et al. 2005, Moyle et al. 2007). Moyle et al. (2007) also found that the majority of fish found stranded in isolated pools and ponds on the Consumnes River floodplain after the flood waters receded were non-native species, although some native species such as Chinook salmon and splittail (*Pogonichthys macrolepidotus*) were seen immediately after the floodplain stopped draining. Predation is also possible, but appears to be offset by the size of the floodplain inundated during flood events. Sommers et al. (2001a) reported that while avian predation was likely, the density of wading birds on the inundated floodplain was low due to the area of habitat flooded, and the variability of the habitat used by fish on the floodplain. Likewise, predation by fish is also likely to occur, but due to the area of inundated habitat, the amount of habitat refugia used by juvenile fish should reduce the probability of encounters with a predator.

Moyle et al. (2007) reported that native fish do best in open floodplain areas covered with annual vegetation and provided suggested guidelines for floodplain restoration. These guidelines include:

1. Provide early season flooding, preferably from early January through April. Flooding can come in pulses, but duration of flooding is also important to maximize the floodplain benefits to native fishes.
2. Create floodplains that drain completely. Avoid artificial structures that obstruct the drainage pattern, and could lead to stranding.

3. Reduce permanent water habitats such as ponds or sloughs. These waterways favor non-native fish species which may be a significant source of predators on juvenile native fish.
4. Maintain a mosaic of habitats on the floodplain.
5. Maintain both a high variability in flood regime and regular annual flooding. High year to year variability in the extent and duration of flooding is both natural and desirable to maintain habitat diversity. Some flooding should occur every year if possible to benefit native fishes.
6. Create experimental habitats to help maintain or re-establish populations of native fishes.
7. Provide long-term monitoring programs to enhance the knowledge of floodplain dynamics.

The new floodplain, as proposed, meets some of these guideline. However the main difference between these guidelines and the proposed floodplain design lies in the frequency and duration of inundation. A floodplain elevation of 14 feet (NAVD88) will only inundate on average every 6 years, based on the Project's modeling. An elevation of 9 to 10 feet (NAVD88) for the levee breach will only allow water onto the floodplain every 2 to 4 years. As designed, only 1 to 2 acres of the restored riparian scrub habitat will be below 14 feet (NAVD88) and has the potential to flood with any frequency. Elevations greater than this on the floodplain will flood only in years when flows on the San Joaquin exceed 24,000 cfs, which is an infrequent occurrence. Thus the full benefits of the newly created floodplain will be greatly diminished for native fish due to the infrequency of the floodplain being activated by high water conditions.

2.5.2 Effects to Critical Habitat

The levee repairs as proposed for the Project will not create any permanent impacts to critical habitat for CCV steelhead or sDPS green sturgeon. All impacts related to the construction phase of the Project will last only as long as the construction actions are taking place, and are therefore transitory in nature. As described in the description of the action, construction will occur between July 1 and November 1 over the planned two year duration of the construction phase. Although the Project's goals are to improve and repair the levees in the RD 17 sphere of operations, none of the Project's actions will physically alter current critical habitat for either CCV steelhead or sDPS green sturgeon as the Project's actions are above the normal high tide elevation on the waterside of the levees and are predominately located from the edge of the levee crown on the waterside of the levee and landwards from the levee crown. Thus, the current condition of the waterside face of the levee is essentially unaltered by the Project's actions except for the location of the levee breach for the new floodplain.

2.5.2.1 CCV Steelhead Designated Critical Habitat

The effects to designated critical habitat for CCV steelhead related to the direct effects of construction actions will be short lived during the construction season. Within the action area of the Project, the PBFs for designated critical habitat for CCV steelhead are freshwater rearing habitat and freshwater migration corridors. The period of active migration for CCV steelhead adults in the San Joaquin River during fall and early winter (Table 6) overlaps with the proposed work window of July 1 through October 31 in the action area. There is a very low probability that juvenile steelhead may be emigrating downstream through this area during the work window, and would likely only do so if flows in the basin tributaries were elevated by storms or reservoir releases.

As described earlier in this document regarding Project effects, the construction actions are anticipated to create elevated levels of noise due to construction equipment moving on the levees and the actual construction activities associated with the levee repairs (i.e., grubbing, excavations, and construction of the slurry cutoff walls). Noise related to construction equipment and vehicles and the proposed construction activities on the levees will degrade the functioning of the waterways as a freshwater migration corridor during the migration period. NMFS expects that fish will be startled by the construction activity and associated noise, temporarily leaving the nearshore area while the construction is taking place. NMFS assumes that fish will move to an area of the river that is quieter and resume holding or upstream movements during their upstream migration phase. Migration during the daytime may be depressed by the construction activities along the levees, and fish will potentially hold until evening and night before moving through the active construction areas when construction activities cease for the night. In those sections of river within the action area where work will occur during the night and lights will illuminate the work area, migratory movements will potentially be delayed or halted until there is a lull in the construction activities or the behavioral need to migrate upstream surpasses the avoidance response of the exposed fish to noise and higher light levels. Overall, the impacts to critical habitat associated with construction related activities, traffic, and noise are expected to be temporary and result in no permanent damage to the PBFs of the designated critical habitat. When construction in a given reach of the levee repair site is completed, the construction related traffic, activities, and noise ends and no further acute construction related impacts will affect the aquatic system.

As previously described in this document, the perpetuation of the levees, their armored riprapped waterside faces, and the removal of vegetation will diminish the functioning of the action area’s waterways for rearing and migration of juvenile CCV steelhead. Levees simplify riverine and estuary habitat complexity and reduce the integrity of the riparian and wetland corridors associated with stream borders and sloughs. Levees also isolate the floodplains from the river, destroying the valuable interface between the riparian and the adjacent aquatic communities that depend on an exchange of inorganic and organic materials to function fully. Riprapping the waterside faces of the levees to provide protection against erosion reduces the ability of riparian vegetation to establish itself, changes the hydrodynamics of the river adjacent to the bank in an ecologically unfavorable manner, and reduces and prevents the establishment of IWM along the river’s edge.

2.5.2.2 sDPS of North American Green Sturgeon

The potential impacts to sDPS green sturgeon critical habitat are similar to that just described for the CCV steelhead critical habitat. The construction actions will create temporary noise impacts on the waterways of the action area as described for the CCV steelhead above. Presence of juvenile sDPS sturgeon, however, are likely to overlap with all of the construction in-water work window since juveniles are expected to be present year round in the action area. Adults are most likely to be present in the winter and spring, but may also be present year round in low numbers. Potential effects range from delay of migration through the affected reaches due to behavioral avoidance of the construction sounds (and potentially increased light levels at night). As described for the CCV steelhead, construction will occur from July 1 to November 1, for two years. There will be no permanent impacts to designated critical habitat due to the construction generated noises, and no noise related effects when construction is not occurring or when construction has been completed after two years.

The long term presence of the levees, with riprapped armored levee faces, will impair the functioning of the riparian and aquatic habitats as already discussed in this Opinion. NMFS expects that food resources will be negatively affected due to a lack of riparian and shallow water habitat that would benefit food webs in the action area. Likewise the benefit of diverse channel morphology and variable flows and water depths that a naturally meandering river channel would provide are prohibited from occurring due to the levee construction and armoring. This affects the quality of the migratory corridor, food resources, and variable water depths identified as PBFs for freshwater riverine habitats.

2.6 Cumulative Effects

"Cumulative effects" are those effects of future state or private activities, not involving Federal activities, that are reasonably certain to occur within the action area of the Federal action subject to consultation (50 CFR 402.02). Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

Some continuing non-Federal activities are reasonably certain to contribute to climate effects within the action area. However, it is difficult if not impossible to distinguish between the action area's future environmental conditions caused by global climate change that are properly part of the environmental baseline *vs.* cumulative effects. Therefore, all relevant future climate-related environmental conditions in the action area are described in the environmental baseline (Section 2.2.4).

2.6.1 Agricultural Practices

Agricultural practices in the Delta may negatively affect riparian and wetland habitats through upland modifications of the watershed that lead to increased siltation or reductions in water flow in stream channels flowing into the Delta. The Delta islands surrounding the action area are primarily agricultural lands with orchards, row crops, and grazing lands for dairy cattle present. Unscreened agricultural diversions throughout the Delta entrain fish including juvenile salmonids and juvenile green sturgeon and are present in the action area within the mainstem San Joaquin River, and Old River. Grazing activities from dairy and cattle operations can degrade or reduce suitable critical habitat for listed salmonids by increasing erosion and sedimentation as well as introducing nitrites, nitrates, ammonia, and other nutrients into the watershed, which then flow into the receiving waters of the Delta. Stormwater and irrigation discharges related to both agricultural and urban activities contain numerous pesticides and herbicides that may negatively affect salmonid reproductive success and survival rates (Dubrovsky et al. 1998, 2000; Daughton 2003).

2.6.2 Increased Urbanization

The action area occurs within the Delta and Stockton regions, which include portions of San Joaquin County. Population is expected to increase by nearly 3 million people by the year 2020 in the Delta region. Expansion of urban development is occurring in the cities of Manteca, Lathrop, Stockton, and Tracy along the I-5 and I-205/580 corridors. Increases in urbanization and housing developments can impact habitat by altering watershed characteristics, and changing both water use and stormwater runoff patterns. Increased growth will place additional burdens on resource allocations, including natural gas, electricity, and water, as well as on infrastructure such as wastewater sanitation plants, roads and highways, and public utilities. Some of these actions, particularly those which are situated away from waterbodies, will not require Federal permits, and thus will not undergo review through the ESA section 7 consultation processes with NMFS.

Increased urbanization also is expected to result in increased recreational activities in the region. Among the activities expected to increase in volume and frequency is recreational boating. There are currently several boating facilities (large private and public facilities with docks, boat launches, and marinas) within the immediate vicinity of the action area. These sites provide recreational boaters access to the Delta. Any increase in recreational boating due to population growth would likely result in increased boat traffic in the action area. Boating activities typically result in increased wave action and propeller wash in waterways. This potentially will degrade riparian and wetland habitat by eroding channel banks and mid-channel islands, thereby causing an increase in siltation and turbidity. Wakes and propeller wash also churn up benthic sediments thereby potentially resuspending contaminated sediments and degrading areas of submerged vegetation. This in turn would reduce habitat quality for the invertebrate forage base required for the survival of juvenile salmonids and green sturgeon moving through the system. Increased recreational boat operation in the Delta is anticipated to result in more contamination from the operation of gasoline and diesel powered engines on watercraft entering the water bodies of the Delta. Furthermore, increased recreational boating, particularly those that can be trailered from one water body to another, greatly increases the risk of spreading non-native invasive species into the Delta.

Increased commercial activity in the Port of Stockton has the potential to increase commercial shipping in the Port of Stockton. Increased commercial shipping increases the potential for spills of petroleum products and other toxic compounds into the Stockton deep water ship channel (DWSC) from the large vessels, as well as the introduction of non-native invasive species into the area waterways through the discharge of ballast waters. Ship movements increase the resuspension of sediments from the channel bottom which may introduce contaminants into the water column and increase turbidity in the DWSC. Finally, increased shipping traffic may increase the risks of propeller entrainment and propeller strikes to listed fish in the DWSC. Propeller strikes are particularly dangerous to adult sturgeon (Brown and Murphy 2010, Balazik et al. 2012).

2.6.3 Rock Revetment and Levee Repair Projects

Cumulative effects include non-Federal riprap projects. Depending on the scope of the action, some non-Federal riprap projects carried out by state or local agencies do not require Federal permits. These types of actions as well as illegal placement of riprap occur within the watersheds of the Sacramento and San Joaquin rivers and their tributaries, as well as the waterways of the Delta. For example, most of the levees have roads on top of the levees which are either maintained by the county, the local reclamation district, the landowner, or by the state. Landowners may utilize roads at the top of the levees to access parts of their agricultural lands and repair the levees to protect property with unauthorized materials (i.e., concrete rubble, asphalt, etc.). The effects of such actions result in continued fragmentation of existing high-quality habitat, and conversion of complex nearshore aquatic to simplified habitats that affect salmonids in ways similar to the adverse effects associated with the Project.

2.7 Integration and Synthesis

The Integration and Synthesis section is the final step in our assessment of the risk posed to species and critical habitat as a result of implementing the proposed action. In this section, we add the effects of the action (Section 2.5) to the environmental baseline (Section 2.4) and the cumulative effects (Section 2.6), taking into account the status of the species and critical habitat (Section 2.2), to formulate the agency's biological opinion as to whether the proposed action is likely to: (1) Reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing its numbers, reproduction, or distribution; or (2) appreciably diminishes the value of designated or proposed critical habitat for the conservation of the species.

2.7.1 Status of CV Spring-run Chinook Salmon

In the 2016 status review (NMFS 2016a), NMFS found, with a few exceptions, that CV spring-run Chinook salmon populations have generally increased through the 2013 returns (23,696 fish total including hatchery fish) but then sharply declined in 2014 (9,901 total fish including hatchery fish; the last escapement numbers available to the TRT since the last status review in 2010/2011). Based on these escapement numbers, the 2016 status review changed the status of the Mill and Deer creek populations from the high extinction risk category, to moderate, while keeping the Butte Creek in the low risk of extinction category. Additionally, the Battle Creek and Clear Creek populations continued to show stable or increasing numbers in that period, putting them at moderate risk of extinction based on abundance. Overall, the Southwest Fisheries Science Center concluded in their viability report that the status of CV spring-run Chinook salmon (through 2014) had probably improved since the 2010/2011 status review and that the ESU's extinction risk may have decreased.

However, adult escapement numbers in 2015 were extremely low. The adult escapement to Central Valley waterways was 1,195 fish. The return to the Feather River Fish Hatchery was 4,440 fish. Returns in 2016 increased slightly but then declined again in 2017. Since the effects of the 2012 to 2016 drought have not been fully realized, NMFS anticipates at least several more years of very low returns, which may result in severe rates of decline (NMFS 2016a).

2.7.2 Status of CCV Steelhead

The 2016 status review (NMFS 2016b) concluded that overall, the status of CCV steelhead appears to have changed little since the 2011 status review when the TRT concluded that the

DPS was in danger of extinction. Furthermore, there is still a general lack of data on the status of wild populations. The Central Valley population of steelhead still faces the loss of the majority of the historical spawning and rearing habitat due to dams and other passage impediments, as well as the other factors previously described for their decline. There are some encouraging signs however, as several hatcheries in the Central Valley have experienced increased returns of steelhead over the last few years. There has also been a slight increase in the percentage of wild steelhead in salvage at the south Delta fish facilities, and the percentage of wild fish in those data remains much higher than at Chipps Island. The new video counts at Ward Dam show that Mill Creek likely supports one of the best wild steelhead populations in the Central Valley, though at much reduced levels from the 1950's and 60's. Restoration efforts in Clear Creek continue to benefit CCV steelhead. However, the catch of unmarked (wild) steelhead at Chipps Island is still less than 5 percent of the total smolt catch, which indicates that natural production of steelhead throughout the Central Valley remains at very low levels. Despite the positive trend on Clear Creek and encouraging signs from Mill Creek, all other concerns raised in the previous status review remain.

2.7.3 Status of sDPS North American Green Sturgeon

The viability of sDPS green sturgeon is constrained by factors such as a small population size, lack of multiple populations, and concentration of spawning sites into just a few locations. The risk of extinction is believed to be moderate because, although threats due to habitat alteration are thought to be high and indirect evidence suggests a decline in abundance, there is much uncertainty regarding the scope of threats and the viability of population abundance indices (NMFS 2015).

Although the population structure of sDPS green sturgeon is still being refined, it is currently believed that only one population of sDPS green sturgeon exists. Lindley et al. (2007), in discussing winter-run Chinook salmon, states that an ESU represented by a single population at moderate risk of extinction is at high risk of extinction over the long run. This concern applies to any DPS or ESU represented by a single population, and if this were to be applied to sDPS green sturgeon directly, it could be said that sDPS green sturgeon face a high extinction risk. However, the position of NMFS, upon weighing all available information (and lack of information) has stated the extinction risk to be moderate (NMFS 2015).

There is a strong need for additional information about sDPS green sturgeon, especially with regards to a robust abundance estimate, a greater understanding of their biology, and further information about their micro- and macro-habitat ecology.

2.7.4 Status of Environmental Baseline and Cumulative Effects in the Action Area

Salmon, steelhead, and green sturgeon use the action area as an upstream and downstream migration corridor and for rearing. Within the action area, the essential features of freshwater rearing and migration habitats for salmon, steelhead and green sturgeon have been transformed from meandering waterways lined with dense riparian vegetation, to a highly leveed system. Levees have been constructed near the edge of the river and sloughs and most floodplains have been completely separated and isolated from the river. Severe long-term riparian vegetation losses have occurred throughout the Delta, and there are large gaps along leveed shorelines devoid of riparian vegetation due to the high amount of riprap. The change in the ecosystem as a result of halting the lateral migration of the river channels, the loss of floodplains, and the removal of riparian vegetation and IWM have likely affected the functional ecological processes that are essential for growth and survival of salmon, steelhead, and green sturgeon in the action area.

The Cumulative Effects section of this opinion describes how continuing or future effects such as the agricultural transformation of the land within the action area, increased runoff and non-point source contaminants, armoring of levees and shoreline modifications, and increased urbanization affect the species in the action area. These actions typically result in habitat fragmentation, and conversion of complex nearshore aquatic habitat to simplified habitats that incrementally reduces the carrying capacity of the rearing and migratory corridors.

2.7.5 Summary of Project Effects on CV Spring-run Chinook Salmon, CCV Steelhead, and sDPS North American Green Sturgeon

2.7.5.1 CV Spring-run Chinook salmon

2.7.5.1.1 Active Construction Related Effects

These effects are related to the immediate acute effects of the construction activities at the repair sites during the July 1 through November 1 construction work window. This will apply to all of the impacted fish species for acute construction related actions.

2.7.5.1.1.1 Temporal and Spatial Overlap

Adults: It is not anticipated that there will be any spatial or temporal overlap between construction activities and the presence of adult spring-run Chinook salmon in the action area. The timing of the construction work window (July 1 through November 1) does not overlap with the anticipated timing of adult spring-run upstream migrations through the Delta and into the San Joaquin River basin (Table 5). Since the likelihood of adult spring-run Chinook salmon presence in the action area at the time of construction activities is remote, NMFS does not anticipate that there will be any affects to individual adult spring-run, and therefore no effects to the ESU.

Juveniles: It is not anticipated that there will be any spatial or temporal overlap between construction activities and the presence of juvenile spring-run Chinook salmon in the action area. The timing of the construction work window (July 1 through November 1) does not overlap with the anticipated timing of the downstream emigration of young-of-the-year spring-run Chinook salmon from the San Joaquin River basin (Table 5). Since the likelihood of juvenile spring-run Chinook salmon presence in the action area at the time of construction activities is remote, NMFS does not anticipate that there will be any affects to individual juvenile spring-run, and therefore no effects to the ESU.

2.7.5.1.1.2 Effects to Individual Fish

Adults - Since it is not expected that any adult spring-run will be present during the construction work window of July 1 to November 1, at any of the repair sites, there are no effects to individual fish.

Juveniles - Since it is not expected that any juvenile spring-run will be present during the construction work window of July 1 to November 1, at any of the repair sites, there are no effects to individual fish.

2.7.5.1.1.3 Effects to the CV Spring-run Chinook salmon ESU

Adults - NMFS expects that there will be no effects to the spring-run ESU due to the lack of effects to individual fish as previously explained.

Juveniles - NMFS expects that there will be no effects to the spring-run ESU due to the lack of effects to individual fish as previously explained.

2.7.5.1.2 Long Term Effects

2.7.5.1.2.1 Temporal and Spatial Overlap

Adults – Returning adults from the SJRRP introductions of spring-run Chinook salmon will migrate upstream in the San Joaquin River each year enroute to the San Joaquin River below Friant Dam. These fish will pass the location of the setback levee and new floodplain. Access to the floodplain would only occur when the area is inundated during the adult migratory period. Adults may potentially migrate into other tributaries of the San Joaquin River such as the Stanislaus, Tuolumne, and Merced rivers as this population re-colonizes former habitat in those watersheds. It is expected that adult spring-run will move through the lower reaches of the San Joaquin River where the Project actions took place relatively quickly, taking from a few hours to a few days to transit these reaches.

Juveniles – Downstream emigration of juvenile spring-run will occur through the winter and spring each year within the mainstem San Joaquin River. A proportion of the juvenile population may leave the mainstem of the river at the Head of Old River and migrate through the Old River/ Middle River complex to the western Delta, avoiding the setback levee area. Most of the young-of-the-year spring-run juveniles are expected to move downstream in the March through May time frame, with a peak in April, when flows from the tributaries are typically elevated. However, some fish may emigrate earlier than March, or later than May, if river flows are elevated during those periods of time. Access to the floodplain would only occur when the floodplain is inundated during juvenile outmigration.

2.7.5.1.2.2 Effects to Individual Fish

Adults - It is not anticipated that adult spring-run Chinook salmon will be substantially affected by the long term effects of the setback levee and new floodplain. Adult Chinook salmon do not feed during their upstream migration, and thus would not benefit from the additional food base created by an inundated floodplain. It is also unlikely that adult fish would consistently be attracted to the floodplain due to the lack of any attractant flows from incoming streams or watercourses. As proposed, most of the floodplain is unlikely to become activated more than once every 3 to 6 years, based on the design elevations. Under lower flow conditions when the floodplain is not inundated, there would be no effect on individual fish. A few fish may hold for a short time due to the velocity break the floodplain would offer from the mainstem flows in the San Joaquin River during the high flow events that would lead to the inundation of the floodplain. The frequency of inundation may increase in the future due to climate change and projected increases in sea level elevations as discussed earlier in this document. However, this increase may take decades to be realized.

Outside of the levee setback area, adult fish would encounter the same altered aquatic habitat due to the continued presence of levees that currently exists into the foreseeable future. This alteration of aquatic habitat and its effects are described in section 2.5.1.5 *Perpetuation of Levee Presence*.

Juveniles – Juvenile spring-run Chinook salmon are expected to utilize the floodplain when it is inundated during their downstream migration in spring. As described above, flows that inundate the floodplain for longer than a few days will enhance the growth potential of the fish rearing on it. Food resources are expected to increase through the growth in biomass of invertebrates occupying the flooded habitat. The inundated floodplain will also offer refuge from high velocity water currents in the mainstem river channel, and provide slightly warmer waters to enhance the bioenergetics of the salmon rearing there. While most of the effects of the inundated floodplain are positive to individual fish, some fish will be lost to predation while rearing on the floodplain or by stranding during the draining of the floodplain. These negative effects are far outweighed by the positive aspects of enhanced juvenile salmon growth that the floodplain can provide. During those periods when San Joaquin River flows are insufficient to inundate the floodplain, fish will not be benefit from the presence of the floodplain. There will be essentially “no effect” of the floodplain if it remains dry and inaccessible to emigrating spring-run juveniles. As proposed, most of the floodplain is unlikely to become activated more than once every 3 to 6 years, based on the design elevations. The frequency of inundation may increase in the future due to climate change and projected increases in sea level elevations as discussed earlier in this document. However, this increase may take decades to be realized.

Outside of the levee setback area, juvenile fish would encounter the same altered aquatic habitat due to the continued presence of levees that currently exists into the foreseeable future. This alteration of aquatic habitat and its effects are described in section 2.5.1.5 *Perpetuation of Levee Presence*.

2.7.5.1.2.3 Effects to the CV Spring-run Chinook salmon ESU

Adults - Since few if any adult spring-run Chinook salmon would be impacted by the long-term habitat effects of the setback levee and floodplain, there will be little impact to the adult fraction of the spring-run ESU from this component of the Project. The ongoing presence of the armored levees and the changes to the aquatic environment they produce will continue to be a negative influence on the viability of the CV spring-run Chinook salmon ESU.

Juveniles – Those juveniles that are able to access the inundated floodplain associated with the setback levee should, overall, see mostly positive growth enhancements. As previously described, some fish may be lost to predation or stranding, but overall, effects should be beneficial to the San Joaquin River basin population. It is postulated that larger Chinook salmon smolts entering the marine environment from the freshwater environment have a higher probability of survival during this transitional phase. A higher rate of survival at this stage can carry through the ocean rearing phase and enhance the number of adults that migrate back into freshwater to spawn. By increasing the adult escapement of spring-run back into the San Joaquin River basin, the overall health of the ESU is enhanced by increasing the population of this diversity group (Southern Sierra Nevada). In contrast, the ongoing presence of the armored levees and the changes to the aquatic environment they produce will continue to be a negative influence on the viability of the CV spring-run Chinook salmon ESU.

2.7.5.2 California Central Valley Steelhead

2.7.5.2.1 Active Construction Related Effects

2.7.5.2.1.1 Temporal and Spatial Overlap

Adults - Adult CCV steelhead will be present in the waterways of the action area during the construction work window of July 1 through November 1. Adult steelhead begin to enter the Delta in July and peak in their abundance in September and October on the Sacramento River side of the Delta. Adult steelhead entering the San Joaquin River basin start to appear in September in low numbers and typically increase in numbers from October through January based on the Stanislaus River weir data. Migration trends after late December are compromised due to the removal of the weir by the end of December in many of the years in which it was operated.

Juveniles – Juvenile steelhead have a very low probability of being present in the action area during the construction work window of July 1 through November 1. Most emigration by juvenile steelhead through the action area occurs from March through May based on data from the Mossdale trawl.

2.7.5.2.1.2 Effects to Individual Fish

Adults - Only adult steelhead that are holding adjacent to or migrating past the levee repair sites will be directly exposed or affected by construction related noise and activities. Those fish that are exposed to the effects of construction activities will encounter short-term (i.e., minutes to hours) construction-related noise depending on how fast they move through the reach of river channel adjacent to the repair site. Although direct injury or harm is unlikely, behavioral avoidance may cause fish to delay their upstream migration or drop back downstream. Fish often respond to construction activities by quickly swimming away from the construction sites, resulting in the majority escaping direct physical injury. This effect is considered a form of harassment that results in take of exposed fish. The probability of an individual fish being present during construction actions in the affected river reaches increases after mid-September. Prior to mid-September, few adult steelhead have been observed passing the Stanislaus River fish weir. This information is used as a surrogate for when fish might be present in the San

Joaquin River system within the action area. Construction at the multiple repair sites is scheduled to occur from July 1 to November 1, giving approximately 45 days of overlap between the presence of adult steelhead and construction actions each year; for a duration of two years of construction. There is approximately 2.5 months (approximately 62 to 77 days) when adult steelhead are less likely to be present in the action area. Since certain construction actions will take place throughout an entire 24 hour period in a day (i.e., cutoff wall construction) there will be no “quiet period” for fish to move upstream without encountering the noise associated with construction actions (as well as night time illumination of the cutoff wall construction locations). Effects related to contaminants and turbidity are not expected to impact adults migrating through the action area due to the implementation of construction BMPs designed to limit these factors and the short duration of exposure anticipated for adults as they move through the action area.

Juveniles - There is a low probability of exposure of juvenile steelhead to the effects of the active construction activities during the work window. This is due to temporal and spatial separation of the Project’s actions with the migratory timing and presence of juvenile steelhead in the San Joaquin River and south Delta. If fish are present, they are unlikely to be exposed to conditions that will cause direct mortality or injury. It is expected that most of the responses of exposed fish will be behavioral in nature (harassment) although some individuals may be lost to predation associated with delays in migrating past the levee repair sites during construction. Predation would be considered a secondary consequence of the Project’s actions.

2.7.5.2.1.3 Effects to the CCV Steel head DPS

Adults - The majority of the currently existing populations of the CCV steelhead DPS originate in the Sacramento River basin (Northwestern California, Northern Sierra Nevada, and the Basalt and Porous Lava diversity groups) and are not expected to be present in the action area. Steelhead from the Southern Sierra Nevada diversity group are expected to be present in the action area, and thus will be affected by the Project’s actions. The majority of adult steelhead migrating upstream are expected to use the mainstem of the San Joaquin River as their migratory route, migrating past the locations of the Project’s repair sites. However, since most of the San Joaquin River basin population (Southern Sierra Nevada diversity group) will be migrating after the end of October when the construction work window ends, the majority of the population will not be exposed to the construction actions and their effects. Since no lethal take of adult steelhead is expected from exposure to the action’s activities and any non-lethal take is expected to be primarily due to harassment of fish by noise and activity, the CCV steelhead DPS will not be negatively impacted by the exposure of the San Joaquin River basin steelhead population to the construction related effects of the action.

Juveniles - As described for the adult steelhead above, the majority of the juvenile steelhead comprising the CCV steelhead DPS originate in the Sacramento River basin and will not be present in the action area. There is a low probability that some juvenile steelhead from the Southern Sierra Nevada diversity group originating in the San Joaquin River basin may emigrate early and be present in the action area during construction activities. These fish will have non-lethal exposures to construction actions associated with the levee repair sites and will continue migrating downstream, although some fish may experience migratory delays due to the effects of the action. A few of those individuals delayed may be predated upon due to an increase in their temporal exposure to predators in the action area. The small numbers of fish migrating during the work window coupled with the small percentage of fish actually lost to the Project's actions will not substantially affect the CCV steelhead DPS viability.

2.7.5.2.2 Long Term Effects

2.7.5.2.2.1 Temporal and Spatial Overlap

Adults - Returning steelhead adults from the Southern Sierra Nevada diversity group will migrate upstream in the San Joaquin River each year enroute to the San Joaquin River basin and its tributaries from approximately mid-September through early winter (January/ February) based on fish passage records from the Stanislaus River fish weir. It should be noted, however, that adult steelhead passage records are truncated artificially by the fish counting weir being removed at the end of December in most years. These fish will pass the location of the setback levee and new floodplain. Adults may potentially migrate into any one of the tributaries of the San Joaquin River such as the Stanislaus, Tuolumne, and Merced rivers to reach their spawning grounds. It is expected that adult steelhead will move through the lower reaches of the San Joaquin River where the Project actions took place relatively quickly, taking from a few hours to a few days to transit these reaches. Some adult steelhead will survive after spawning and return downstream as "kelts" through the action area. It is expected that kelts will migrate through the action area later in the year, typically in winter and spring.

Juveniles - Downstream emigration of juvenile steelhead will typically occur through the winter and spring each year within the mainstem San Joaquin River. A proportion of the juvenile population may leave the mainstem of the river at the Head of Old River and migrate through the Old River/ Middle River complex to the western Delta, avoiding the setback levee area. Most of the juvenile steelhead are expected to move downstream from March through May, peaking in April and May, when flows from the San Joaquin River basin tributaries are typically elevated. However, some fish may emigrate earlier than March, or later than May, if river flows are elevated during those periods of time.

2.7.5.2.2.2 Effects to Individual Fish

Adults – The majority of adult steelhead moving upstream towards spawning locations will pass the location of the setback levee and the new floodplain on the San Joaquin River. Only those fish which move through Old River will bypass the location. Fish will only be able to gain access to the floodplain when water elevations are sufficiently high to inundate the levee breach and those portions of the floodplain with the lowest elevations. These inundations must happen when the adults are migrating past the location of the levee breech. Since most adult steelhead are typically making their way upstream before there are sufficiently elevated flows in the San Joaquin River to inundate the breech and floodplain, the majority of adults will never be present when the floodplain is inundated and thus will not benefit from it. A smaller fraction of the adult population may move upstream in winter when there is the potential for elevated flood flows. As proposed, most of the floodplain is unlikely to become activated more than once every 3 to 6 years, based on the design elevations. Under lower flow conditions when the floodplain is not inundated, there would be no effect on individual fish. However, if the floodplain is inundated, individual fish could move onto the floodplain and take advantage of velocity refugia from the main river channel to rest and hold during their upstream migration. Kelts moving back downstream after spawning in winter and spring have a higher likelihood of encountering the floodplain when it is inundated, as higher river flows typically occur during this period of time. Although the activated floodplain is likely to provide enhanced forage base from increased invertebrate production, adult steelhead engage in minimal feeding during their upstream spawning migration and this benefit is unlikely to be used during their upstream spawning migration. However the floodplain can provide this benefit to kelts moving back downstream following spawning, when the adult fish begin to regularly feed again. In addition, native fish are likely to use the inundated floodplain to spawn if the duration of flooding is long enough, and this boost to native fish populations could in turn provide additional forage base for adult steelhead to feed upon while migrating through the system.

Outside of the levee setback area, adult fish would encounter the same altered aquatic habitat due to the continued presence of levees that currently exists. This alteration of aquatic habitat and its effects are described in section 2.5.1.5 *Perpetuation of Levee Presence*.

Juveniles – Juvenile steelhead from the San Joaquin River basin will typically migrate through the action area from January through June with the majority of the population emigrating from March through May. The peak of emigration, based on observations at the Mossdale trawl location near the Head of Old River, is during April and May. A fraction of the emigrating steelhead juveniles may take the Old River channel at the Head of Old River bifurcaton. These fish will not be exposed to those portions of the action area downstream of the bifurcation, including the setback levee and flood plain. For those fish that continue down the main channel of the San Joaquin River, they may be exposed to the effects of the new floodplain. Fish will only be able to gain access to the floodplain if the water elevations are sufficiently high enough to inundate the levee breach and those portions of the floodplain with the lowest elevations. As proposed, most of the floodplain is unlikely to become activated more than once every 3 to 6 years. Under these lower flow conditions, the floodplain would have no effect on individual fish. However, if the floodplain is inundated, individual fish could move onto the floodplain and take advantage of velocity refugia from the main river channel to rest and hold during their downstream migration.

Steelhead juveniles holding on the floodplain can also benefit from preying on both the increased invertebrate production associated with inundated floodplains and potentially larval fish from floodplain spawners using the floodplain habitat. These fish are expected to grow larger than those steelhead juveniles that remain in the main channel. Growing larger is expected to enhance survival of juvenile steelhead moving from the freshwater environment to the marine environment due to larger energy stores from the additional caloric intake gained from feeding on the floodplain.

Outside of the levee setback area, juvenile fish would encounter the same altered aquatic habitat due to the continued presence of levees that currently exists into the foreseeable future. This alteration of aquatic habitat and its effects are described in section 2.5.1.5 *Perpetuation of Levee Presence*.

2.7.5.2.2.3 Effects to the CCV Steelhead DPS

Adults – There will be a slight positive effect on the CCV steelhead DPS as a result of the setback levee and the newly created floodplain in regards to its use by adult steelhead from the San Joaquin River basin (Southern Sierra Nevada diversity group). The primary reason that there would not be a more positive response is the infrequent inundation of the floodplain by elevated river flows at a time when adult steelhead are present. As designed, the levee breech and floodplain will only be activated by floodwater inundation every ~3-6 years, and this would typically occur when most adult steelhead are not present during their upstream migration. Thus, benefits of the floodplains will not be available to every year's returning adult escapement population. The frequency of inundation may increase in the future due to climate change and projected increases in sea level elevations as discussed earlier in this document. However, this increase may take decades to be realized. The ongoing presence of the armored levees and the changes to the aquatic environment they produce will continue to be a negative influence on the viability of the CCV steelhead DPS.

Juveniles – It is expected that there will be an overall positive effect on the CCV steelhead DPS due to the utilization of the floodplain by juvenile steelhead. This benefit will occur only to the fish belonging to the Southern Sierra Nevada diversity group, the only diversity group which occupies the San Joaquin River basin. Benefits will be derived from using the floodplain as a refugia from high river flows, a place to rear, and a place to forage on the increased invertebrate and larval fish populations (i.e., native fish species that are floodplain spawners) expected from the created floodplain habitat. It is expected that these juvenile steelhead will be larger and have better overall survival when moving downstream to the marine environment. If the population of steelhead entering the ocean has better initial survival, then there may be more fish surviving to return to spawn in the San Joaquin River basin following their ocean residency phase. Increasing the population of the Southern Sierra Nevada diversity group aids in the recovery of the CCV steelhead DPS by increasing the viability of this diversity group, and hence the overall viability of the DPS. This positive effect on the DPS would be greater if the frequency and duration of the floodplain inundation increased, which may occur in the future due predicted climate change and projected increases in sea level elevations. In contrast, the ongoing presence of the armored levees and the changes to the aquatic environment they produce will continue to be a negative influence on the viability of the CCV steelhead DPS.

2.7.5.3 sDPS of North American Green Sturgeon

2.7.5.3.1 Active Construction Related Effects

2.7.5.3.1.1 Temporal and Spatial Overlap

Adults - Adult green sturgeon are expected to be present year-round in the Delta. Peak presence is during the upstream spawning migration into the Sacramento River from approximately February through June. Post-spawn adults move back downstream following spawning, but spend varying lengths of time resting upriver before returning downstream. Less is known regarding their potential use of the San Joaquin River basin upstream of the Delta, but CDFW sturgeon report card information and the observation of a live green sturgeon in the Stanislaus River in October 2017, indicate that there is opportunistic use of this watershed. The information provided in the CDFW sturgeon report cards indicates that green sturgeon have been caught during all seasons of the year in the San Joaquin River basin, but primarily from fall through spring. Few fish are caught during the summer period.

Juveniles - Juvenile green sturgeon may rear for up to three years in the Delta before finally emigrating to the marine environments along the continental shelf. It is believed that juveniles make use of all accessible waterways in the Delta to rear during this period, including all of the waters in the action area.

2.7.5.3.1.2 Effects to Individual Fish

Adults - For those adults that are in proximity to the levee repairs sites during active construction, NMFS believes that only non-lethal behavioral modifications will occur. NMFS does not anticipate that any lethal effects will occur to adults following exposure to noise, vibrations, nocturnal illumination from construction lights, or bank-side activities related to the construction activities. Exposed fish are expected to move away from the disturbance and noise to waters that are quieter and have less activity, resuming foraging or holding behavior. Any delays to movements are temporary. For most of the construction sites, fish can continue their movements during the night when construction activities cease until the next morning. For the two locations that will have continuous cutoff wall construction, fish will have their movements delayed or prevented. Some fish may eventually move past construction activities when their behavioral drive and needs supersedes their avoidance response to the disturbance.

NMFS does not expect any demonstrable effects to adult green sturgeon due to turbidity or contaminants related to Project activities. The Project will adhere to construction BMPs that will minimize the effects or potential release of turbidity plumes. Any turbidity associated with the Project’s actions is not anticipated to reach a magnitude that would adversely affect green sturgeon, a species that is typically found in the turbid waters of the Delta and San Francisco Bay estuary. The release of contaminants is also unlikely due to the spill prevention and clean up components of the Project’s BMPs. These components of the BMPs are designed to prevent spills or leaks before they can occur, and if they do occur, quickly containing them and cleaning them up before they can enter adjacent waterways.

Juveniles - Effects to juveniles are expected to be the same as those described for adult green sturgeon. NMFS does not anticipate any lethal effects from construction activities. Like the effects to adults, juveniles are most likely to have behavioral modifications. Fish are expected to move away from noise and disturbances to quieter areas of the adjacent waterways, and resume their normal behaviors. These effects are considered non-lethal and temporary in duration.

2.7.5.3.1.3 Effects to the sDPS of North American Green Sturgeon

Adults - No effects to the viability of the sDPS of green sturgeon are expected from the exposure to Project’s construction activities. Since exposure to the effects will result in only non-lethal responses, which are temporary in nature, there are no lasting effects to the individual fish and hence the DPS as a whole.

Juveniles - There are no effects to the viability of the sDPS of green sturgeon due to exposure of juveniles to the Project's construction activities. Since only non-lethal behavioral effects are expected, and individuals are anticipated to fully recover from these effects, there are no losses of any individual fish to the overall population. Thus there is no diminishment in abundance or any of the other elements that affect the viability of the DPS.

2.7.5.3.2 Long Term Effects

2.7.5.3.2.1 Temporal and Spatial Overlap

Adults - The temporal and spatial distribution of adult green sturgeon in relationship to the action area is the same as previously described for section 2.7.5.3.1.1. Since adult green sturgeon are present year-round in the action area, there is no discernable difference in the distribution of adults between the acute construction phase and the long-term project effects in the action area.

Juveniles – The temporal and spatial distribution of juvenile green sturgeon in the action area is the same as previously described for section 2.7.5.3.1.1. Since juvenile green sturgeon are present year-round in the action area, there is no discernable difference between the distribution of juveniles in the acute construction phase and the long-term project effects phase.

2.7.5.3.2.2 Effects to Individual Fish

Adults – Adult green sturgeon may benefit from the creation of the floodplain habitat through the increase in invertebrate biomass that will come off of the floodplain as it drains and which has the potential to provide additional forage base to adults. Some sturgeon may swim up onto the floodplain to forage if water depth is sufficient, but use of the floodplain by adults is uncertain. In addition, when the floodplain is activated by inundation, organic material and nutrients will come off the floodplain and provide benefits to downstream aquatic habitats. However, as previously described, the benefits of the floodplain will only occur when the floodplain is inundated, which will occur every 3 – 6 years based on the proposed elevations of the levee breech and floodplain. The frequency of inundation may increase in the future due to climate change and projected increases in sea level elevations as discussed earlier in this document. However, this increase may take decades to be realized.

Outside of the levee setback area, adult fish would encounter the same altered aquatic habitat due to the continued presence of levees that currently exists. This alteration of aquatic habitat and its effects are described in section 2.5.1.5 Perpetuation of Levee Presence.

Juveniles – Juveniles are also expected to benefit from the inundated floodplain in the same manner as adults. Juveniles are expected to make more use of the floodplain than adults due to their smaller size and the relative depth of water on the floodplain during inundation when compared to their size. The frequency of inundation is projected to be every 3 to 6 years, but may increase in the future due to climate change and projected increases in sea level elevations as discussed earlier in this document. However, this increase may take decades to be realized.

Outside of the levee setback area, juvenile fish would encounter the same altered aquatic habitat due to the continued presence of levees that currently exists. This alteration of aquatic habitat and its effects are described in section 2.5.1.5 Perpetuation of Levee Presence.

2.7.5.3.2.3 Effects to the sDPS of North American Green Sturgeon

Adults - There will be a slight positive effect on the sDPS of North American green sturgeon as a result of the setback levee and the newly created floodplain in regards to the increased food resources for adults that the floodplain can potentially provide. There would be more positive effects to the sDPS of green sturgeon if the inundation frequency of the floodplain was higher. The frequency of inundation may increase in the future due to climate change and projected increases in sea level elevations as discussed earlier in this document. However, this increase may take decades to be realized. The ongoing presence of the armored levees and the changes to the aquatic environment they produce will continue to be a negative influence on the viability of the sDPS of green sturgeon.

However, the overall magnitude of long term effects of the Project to the sDPS of green sturgeon are diminished due to the location of the action area in the southern Delta; a region of the Central Valley that is not used extensively by this species. It is anticipated that only a small fraction of the population of green sturgeon from this DPS will be present within the action area affected by the setback levee and thus be exposed to its impacts.

Juveniles – There will be beneficial effects to the sDPS of green sturgeon in relation to juvenile use of the floodplain. Increased invertebrate production originating on the floodplain should increase the forage base of juvenile green sturgeon. Increased flow of nutrients and organic matter from the floodplain should enhance downstream aquatic habitat which will in turn benefit juvenile green sturgeon rearing in those waters. But like adults, these benefits are less than what is possible due to the infrequent inundation of the floodplain and its activation by floodwaters. Benefits to the sDPS of green sturgeon are likely to occur only once every 3-6 years, but may increase due to climate change and more frequent inundation as discussed in previous sections of this opinion. In contrast, the ongoing presence of the armored levees and the changes to the aquatic environment they produce will continue to be a negative influence on the viability of the sDPS of green sturgeon.

As discussed above for adult green sturgeon in the sDPS, the overall magnitude of impacts to juvenile green sturgeon from the Project over the long term are minimized due to the Project's location in the southern Delta. A small fraction of the overall population of sDPS green sturgeon are expected to be found in this region compared to the Sacramento River watershed and remainder of the Delta.

2.7.6 Summary of Project Effects on CCV steelhead and sDPS Green Sturgeon Critical Habitat

Within the Project's action area, there is designated critical habitat for CCV steelhead, and sDPS green sturgeon. The action area does not include designated critical habitat for CV spring-run Chinook salmon.

The relevant PBFs of the designated critical habitat for steelhead are migratory corridors and rearing habitat, and for green sturgeon the six PBFs include food resources, substrate type/size, flow, water quality, migration corridor free of passage impediments, depth (holding pools), and sediment quality.

Migration may be temporarily delayed due to noise and bankside activities for CCV steelhead smolts in those rare cases when they may be present during the work window for construction. The PBF of migratory corridors for adult steelhead are expected to be impacted due to the timing of the adult migration. Although migrating adult steelhead are unlikely to use the nearshore habitat that will be most affected by this project, preferring to use the deeper water of the channel thalweg for migratory movements, the sound pressure waves and particle movement caused by construction will carry across the width of the channels at each repair location. These delays to migration will be temporary in most of the river reaches adjacent to construction sites as fish can move again at night when construction ceases. This occurs at most of the construction sites, but not at sites Va and VI a.1 where construction is anticipated to occur 24 hours a day, 7 days per week. On the other hand, fish can simply pass through the disturbances as it happens since the magnitude of sound energy will never reach the level of injury or mortality, but is only a behavioral deterrent to passage. Once the behavioral drive of the fish to move exceeds the avoidance behavior caused by the disturbance, the fish may choose to swim through the reach impacted by the sounds and vibrations. Furthermore, the construction related sound delays will last approximately four months each construction season (2 seasons total) at each repair site location, then cease with the end of construction. The Project did not install any features that are expected to permanently block or impede juvenile or adult migration.

The green sturgeon PBF of an unobstructed migratory corridor free of passage impediments is expected to be adversely affected by the project. Construction noise and activities may cause a delay in green sturgeon movements for both adult and juvenile fish. However, as described in the effects synthesis above, these delays are transitory as fish can move at night in most cases to avoid the noise or simply move to another area of the river to carry out their normal behaviors, including feeding and holding. Furthermore, the delays are of a temporary nature as the construction at each site will last only four months each construction season, and then the construction related sounds will cease with the conclusion of construction activities. Only two construction seasons are anticipated for this Project.

As previously described for the effects of the inundated floodplain on individual fish, the floodplain may benefit the functioning of the PBFs for both steelhead and green sturgeon by enhancing food resources which in turn enhance the quality of the rearing habitat. This benefit to the PBFs for steelhead and green sturgeon will be limited however by the low frequency of inundation of the floodplain. When the floodplain is not inundated, it does not provide the benefit to the PBFs of the steelhead and green sturgeon designated critical habitats in the action area.

2.8 Conclusion

After reviewing and analyzing the current status of the listed species and critical habitat, the environmental baseline within the action area, the effects of the proposed action, any effects of interrelated and interdependent activities, and cumulative effects, it is NMFS' biological opinion that the proposed action is not likely to jeopardize the continued existence of CV spring-run Chinook salmon, CCV steelhead, and sDPS of the North American green sturgeon. The project will not adversely modify designated critical habitat for CCV steelhead, or the sDPS of North American green sturgeon. Designated critical habitat for CV spring-run Chinook salmon does not occur within the action area of this Project.

2.9 Incidental Take Statement

Section 9 of the ESA and Federal regulations pursuant to section 4(d) of the ESA prohibit the take of endangered and threatened species, respectively, without a special exemption. "Take" is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. "Harm" is further defined by regulation to include significant habitat modification or degradation that actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including breeding, spawning, rearing, migrating, feeding, or sheltering (50 CFR 222.102). "Incidental take" is defined by regulation as takings that result from, but are not the purpose of, carrying out an otherwise lawful activity conducted by the Federal agency or applicant (50 CFR 402.02). Section 7(b)(4) and section 7(o)(2) provide that taking that is incidental to an otherwise lawful agency action is not considered to be prohibited taking under the ESA if that action is performed in compliance with the terms and conditions of this ITS.

2.9.1 Amount or Extent of Take

In the biological opinion, NMFS determined that incidental take is reasonably certain to occur as follows:

NMFS anticipates incidental take of CV spring-run Chinook salmon, CCV steelhead, and the sDPS of North American green sturgeon in the action area through the implementation of the proposed Project. Because of the proposed timing of the in-water work for the construction phase of the Project, actual numbers of fish adversely affected by the construction actions are expected to be low. Only adult CCV steelhead and juvenile and adult sDPS green sturgeon will be present in the action area in any substantial numbers during the construction period, but may not always be present at the levee repair sites during actual construction due to the variability in spatial and temporal distribution within the action area. Only very small numbers of individual juvenile steelhead from the CCV steelhead Southern Sierra Nevada diversity group are expected to be present in the action area during the construction period. Greater numbers of individuals from the three listed species are expected to be present in the action area over the long term, and will be present in the action area in greater numbers than during the construction phase. These fish will be exposed to the post-construction levee repair sites, including the setback levee and floodplain and take will occur.

However, while individual fish will be present in the action area, NMFS cannot, using the best available information, precisely quantify and track the amount or number of individuals that are expected to be incidentally taken (injure, harm, kill, etc.) per species as a result of the proposed action. This is due to the variability and uncertainty associated with the response of listed species to the effects of the proposed action, the varying population size of each species, annual variations in the timing of spawning and migration, individual habitat use within the action area, and difficulty in observing injured or dead fish. However, it is possible to estimate the extent of incidental take by designating as ecological surrogates, those elements of the project that are expected to result in incidental take, that are more predictable and/or measurable, with the ability to monitor those surrogates to determine the extent of take that is occurring.

The most appropriate threshold for incidental take, is an ecological surrogate of habitat disturbance, which includes the factors (construction area containing the Project actions) causing fish to relocate and rear in other locations and reduce the carrying capacity of the existing habitat. NMFS will describe (1) the causal link between the surrogate and take of the species; (2) why it is not practical to express the amount of anticipated take or to monitor take related impacts in terms of individuals of the listed species; and (3) sets a clear standard for determining when the amount or extent of the taking has been exceeded.

The behavioral modifications of fish responses that result from the habitat disturbance are described below. NMFS anticipates annual take during the 2 years of construction activities will be limited to the following forms:

Incidental take will be primarily in the form of harassment to migrating CCV steelhead adults and juvenile and adult sDPS green sturgeon due to the repair of a cumulative 26,000 linear feet of levee within the RD 17 levee system as proposed under the Project. Levee repairs will affect adult CCV steelhead and adult and juvenile sDPS green sturgeon through displacement of fish from preferred locations in the river channel used for holding, rearing, and feeding, and the delay of migratory behavior within the affected river reaches. Although their presence is unlikely due to their migratory timing, exposure of CCV steelhead smolts may occur in rare instances, and is included as part of the ITS for this Project. Juvenile steelhead that are displaced from preferred locations in the riverine channel or delayed in their migratory behaviors may also have an enhanced level of predation due to increased exposure to predators both spatially and temporally as they attempt to avoid the shore side disturbances.

Construction actions along the 26,000 linear feet of levee alignment in the RD 17 action area associated with the Project will be the cause of disturbances that will impact listed fish. Construction actions will create the noise, vibrations, and shore side activities that will cause the harassment of exposed fish that are adjacent to the locations of the Project's different elements. Construction actions along the levees within the action area are directly linked to the footprint of the repair elements and their associated river reaches. Levee repair construction actions associated with the Project will not occur outside of the Project element footprints as described in the BA.

Since it is unlikely that individual fish and their responses to the construction actions will be visible to shore side observation due to water depth and lack of water clarity, the physical footprint of each Project element serves as the proxy for the extent of Project related impacts to listed fish. Each of the Project's elements are described in Table 1, which provides the linear feet of remaining levee repairs to be completed under the Project. The following table (Table 9) describes these physical attributes. These physical attributes describe the length of aquatic habitat disturbance that represents the ecological surrogate of take at each Project element.

Table 9: Ecological Surrogates for the Incidental Take of Listed Species due to Phase 3 of the RD17 Levee Repair Project's Construction Elements

Site/Element	Project Related Actions to Complete Levee Rehabilitation		
	Seepage Berm (feet)	Chimney Drain (feet)	Cutoff Wall (feet)
I a	240*	590	0
I b	0	130	0
I e	0	590	0
II ab	0	0	2,600
III a	0	4,750	0
IV a	0	720	0
IV c	300	0	300
V a and VI a.1	0	0	9,500
VI a.4	0	0	70
VI b	0	0	2,00
VI c	0	300	0
VI d	0	150	0
VI e	0	250	0
VI b	0	350	0
VII e	0	0	2,500
VII g	400	0	0
Sum	940	8,280	17,020

*The 240 feet of seepage berm to be constructed overlaps with the 590 feet of chimney drain to be constructed.

Incidental take of listed fish will occur over the long term in response to the creation of the setback levee and the new floodplain. Even though the creation of floodplain habitat for native fish (including listed fish species) will be of great benefit to these populations, a small number of juvenile CV spring-run Chinook salmon, CCV steelhead, and sDPS green sturgeon are expected to be lost due to predation of juvenile fish while rearing or otherwise using the floodplain. Although unlikely for native fish such as Chinook salmon, steelhead, or green sturgeon, stranding of adult or juvenile fish in depressions or pools can occur when flood waters recede from the floodplain, particularly if the recession of floodwaters occurs quickly. The absolute magnitude of loss due to predation and stranding is expected to be related to the area of the floodplain that is inundated during each flooding event. Due to the variability in the numbers of listed fish and/or predators present on the floodplain at any given time, variations in inter-annual listed fish population size, and the inherent variability of listed fish behavior and usage of the different floodplain habitats, it is not possible to precisely quantify the numbers of listed fish that may be lost due to predation or stranding. The appropriate ecological proxy for quantifying the incidental take of listed fish due to stranding or predation on the floodplain is the area of floodplain that is expected to be inundated during flood flows. Since flood flows will vary from event to event both within years and between years, NMFS will use the maximum area of the floodplain habitat (6.1 acres) to arrive at an upper limit for the area of floodplain that may become inundated from the highest flood flows anticipated.

Incidental take will be exceeded if the amount of habitat disturbance related to construction is exceeded (26,000 linear feet of levee) or the area of the floodplain created by the setback levee exceeds 6.1 acres.

2.9.2 Effect of the Take

In the biological opinion, NMFS determined that the amount or extent of anticipated take, coupled with other effects of the proposed action, is not likely to result in jeopardy to the CV spring-run Chinook salmon ESU, the CCV steelhead DPS, or the sDPS of North American green sturgeon or destruction or adverse modification of designated critical habitat of the CCV steelhead or sDPS of North American green sturgeon occurring within the action area.

2.9.3 Reasonable and Prudent Measures

"Reasonable and prudent measures" are nondiscretionary measures that are necessary or appropriate to minimize the impact of the amount or extent of incidental take (50 CFR 402.02).

1. Measures shall be taken by the USACE or their permittees to minimize or avoid deleterious effects of the Project on listed CV spring-run Chinook salmon, CCV steelhead and sDPS green sturgeon.

2. The USACE shall ensure that RD 17 or its agents, implements all avoidance and minimization measures described in the project description for Phase 3 of the RD 17 Levee Seepage Repair Project.

2.9.4 Terms and Conditions

The terms and conditions described below are non-discretionary, and the USACE or any applicant must comply with them in order to implement the RPMs (50 CFR 402.14). The USACE or any applicant has a continuing duty to monitor the impacts of incidental take and must report the progress of the action and its impact on the species as specified in this ITS (50 CFR 402.14). If the entity to whom a term and condition is directed does not comply with the following terms and conditions, protective coverage for the proposed action would likely lapse.

1. The following terms and conditions implement reasonable and prudent measure 1:

    a. Continuous construction operations shall be restricted to the period between July 1 and September 15 of each construction season. Between September 16 and November 1 of each construction season, work will cease for 1.5 hours before sunset or sunrise and resume 1.5 hours after sunrise or sunset. This will give a cumulative period of 6 hours free from construction related noise and a period of natural lighting conditions during the crepuscular period of fish movement.

    b. Illumination of night time work will require that construction lighting utilize diffusers to reduce the extent of back scatter and glare. All lighting will be directed away from the water's surface and directed landwards towards the ground. Artificial lighting on construction sites will comply with 1a above.

c. Floodplains associated with the setback levee will be inspected during the recession phase after each high water event that inundates the floodplain. The floodplain will be inspected for potential stranding sites that may entrap listed fish. Should stranding events occur, the USACE, RD 17, or its agents, shall engage in fish rescue actions to remove listed fish from the stranding locations and return them to the San Joaquin River. RD 17 shall develop a fish rescue protocol and submit it to NMFS for review 30 days prior to the initiation of construction at the address in 2(i) below. Upon approval by NMFS, the fish rescue protocol will be implemented by RD 17 or its agents to rescue any stranded listed fish.

d. Any locations identified as a fish stranding location shall be filled in or modified to prevent future stranding. This may include filling in any depressions or scour holes by grading or placing new soil fill materials.

e. Any pile driving of sheet piles for the cutoff wall at Element VII will use a vibratory pile driving hammer between September 16 and November 1 to install the sheet piles. Use of an impact pile driving hammer is permissible between July 1 and September 15 to install the sheet pile cutoff wall at this location. However NMFS prefers that vibratory pile driving hammers be used during the entire construction window to minimize or avoid negative effects to aquatic organisms in the adjacent river during pile driving actions.

2. The following terms and conditions implement reasonable and prudent measure 2:

a. The USACE shall ensure that RD 17 or its agents, through the terms of the issued permits, requires all contractors and personnel involved with this Project to be educated and informed of the Terms and Conditions of this biological opinion and the avoidance and minimization measures described in the project description.

b. The USACE shall ensure that RD 17 or its agents, develops and delivers a worker environmental awareness training program to NMFS prior to initiating project activities for NMFS approval. Following NMFS approval of the training program, RD 17 shall provide written documentation of environmental training of all personnel involved in the construction of the project to NMFS. This documentation shall be delivered to NMFS within 30 days of the completion of personnel training.

c. All biologists engaged in the implementation of the Project's avoidance and minimization measures shall be qualified to carry out their duties. All biologists shall present their qualifications to NMFS for approval at least 30 days prior to engaging in project activities.

d. The USACE shall ensure that copies of all permits required for the Project will be delivered to NMFS at least 30 days prior to initiation of construction actions. This shall include, but is not limited to, the USACE's permits issued under section 404 of the Clean Water Act, and sections 10 and 14 (section 408) of the Rivers and Harbor Act, as well as any permits issued by the State of California (i.e., Clean Water Act section 401 permit, NPDES permit, streambed alteration permit, etc.).

e. At least 30 days prior to initiation of construction, a full and complete copy of the Project's SWPPP will be delivered to NMFS. The SWPPP will also include the following requirements:

   i. RD 17 will report any spills over 5 gallons to NMFS immediately (within 24 hours) following their occurrence. This notification will include identifying the composition of the spilled materials, the volume of the spill, and the cleanup procedures implemented.

   ii. Within 15 working days, a summary report of the effectiveness of the cleanup efforts will be delivered to NMFS.

   iii. Within 60 days of the completion of the Project's construction actions, a summary report regarding the SWPPP's effectiveness and the final disposition of any spill responses will be delivered to NMFS.

f. At least 30 days before the initiation of construction, a finalized copy of the Conceptual MMP will be delivered to NMFS. This document will include the final floodplain and levee breech elevations for the setback levee area.

g. Within 60 days of completing the construction activities associated with the Project, RD 17 shall submit a report to the USACE and NMFS summarizing the work that was performed, the starting and ending dates of the construction actions, any observed adverse effects to aquatic habitats and their duration (i.e., increased suspended sediment levels or turbidity, instances of pollution, unusual animal behaviors in adjacent waters, etc.), any problems encountered during construction activities, and any adverse effects to Chinook salmon, steelhead, or green sturgeon associated with the construction activities that was not previously considered.

h. All reports and documents will be sent to the address provided in 2(i) to deliver materials to NMFS.

i. Any Chinook salmon, steelhead, or green sturgeon found dead or injured within 0.25 mile upstream or downstream of any individual construction sites during levee repairs shall be reported immediately to NMFS via fax or phone within 24 hours of discovery to:

Attention: Assistant Regional Administrator
NMFS California Central Valley Office
Fax at (916) 930-3623, or
Phone at: (916) 930-3600

A follow-up written notification shall also be submitted to NMFS which includes the date, time, and location that the carcass or injured specimen was found, a color photograph, the cause of injury or death, if known, and the name and affiliation of the person who found the specimen. Written notification shall be submitted within 72 hours of discovery to:

Assistant Regional Administrator
California Central Valley Office
National Marine Fisheries Service
650 Capitol Mall, Suite 5-100
Sacramento, California 95814

Any dead specimen(s) should be placed in a cooler with ice and held for pick up by NMFS personnel or an individual designated by NMFS to do so.

2.10 Conservation Recommendations

Section 7(a)(1) of the ESA directs Federal agencies to use their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of the threatened and endangered species. Specifically, conservation recommendations are suggestions regarding discretionary measures to minimize or avoid adverse effects of a proposed action on listed species or critical habitat or regarding the development of information (50 CFR 402.02).

1. The Corps should minimize any potential for take whenever possible, and implement practices that avoid or minimize negative impacts to listed salmon, steelhead, and sturgeon and their critical habitat.

2. The Corps should support and promote aquatic and riparian habitat restoration within the Delta and other watersheds, especially those with listed aquatic species. Practices that avoid or minimize adverse effects to listed species should be encouraged.

3. The Corps should continue to work cooperatively with State and Federal agencies, private landowners, regional governments, and local watershed groups to identify opportunities for cooperative analysis and funding to support salmonid habitat restoration projects.

4. The Corps should make set-back levees integral components of their authorized bank protection or ecosystem restoration efforts.

5. The Corps should conduct or fund studies to identify set-back levee opportunities, at locations where the existing levees are in need of repair or where set-back levees could be built in the future. Removal of the existing riprap from the abandoned levee should be investigated in restored sites and anywhere removal does not compromise flood safety.

These conservation recommendations are complimentary to the needs described in the NMFS Recovery Plan for the Sacramento River winter-run Chinook salmon and CV spring-run Chinook salmon ESUs and the CCV steelhead DPS (NMFS 2014). In particular, these conservation recommendations support Delta Recovery Actions as described in the NMFS Recovery Plan. The restoration of riparian and floodplain habitat, tidal marshes, and the creation of setback levees are described in the Recovery Plan as actions that would substantially benefit the ecological functioning of waterways in the Delta region and thus improve the value of designated critical habitat for listed salmonid species in the Delta region.

Implementation of the conservation recommendations by the USACE will enhance nearshore, tidal marsh, and riparian habitat in the Delta where there is currently a considerable deficit of these types of habitats. As previously discussed in this opinion, these types of habitats have been extensively reduced or eliminated in the Delta region by anthropogenic related changes to the landscape. In particular, construction of armored levees along hundreds of miles of waterways in the Delta region and along tributaries and rivers entering the Delta to provide for flood control and to reclaim land for human use have disconnected the aquatic systems from their riparian and floodplain habitats. Loss of these riparian and floodplain habitats have been extremely detrimental to listed salmonid species, as well as most native fish species in the Delta region, which have evolved to use these types of habitats during one or more phases of their life histories. Restoring these habits and providing renewed access to them will benefit listed species as well as native species that depend upon them for their long term survival.

The following Delta Recovery Actions represent actions from the NMFS Recovery Plan which identified the USACE as a potential partner and collaborator and are compatible with the conservation recommendations provided above:

- Del 1.4 — Landscape level restoration of ecological functions in the Delta.
- Del 1.6 — Provide access to new floodplain habitat in the South Delta for salmonids from the San Joaquin River system.
- Del 1.7 — Restore, improve, and maintain salmonid rearing and migratory habitats in the Delta.
- Del 1.13 -1.17 — Restoration of tidal marsh habitat within the Delta at multiple locations.
- Del 2.1 — Flood control improvements on the McCormick-Williamson Tract.
- Del 2.2 – 2.11 — Riparian and tidal marsh habitat restoration actions throughout the Delta – sites with secondary priority action status.
- Del 2.15 — Use alternatives to rip-rap for providing bank stabilization along Delta waterways.
- Del 2.16 — Increase monitoring for and enforcement of illegal rip-rap applications in the Delta.

In order for NMFS to be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, NMFS requests notification of the implementation of any conservation recommendations.

2.11 Reinitiation of Consultation

This concludes formal consultation for the Phase 3 RD 17 Levee Seepage Repair Project.

As 50 CFR 402.16 states, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained or is authorized by law and if: (1) The amount or extent of incidental taking specified in the ITS is exceeded, (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion, (3) the agency action is subsequently modified in a manner that causes an effect on the listed species or critical habitat that was not considered in this opinion, or (4) a new species is listed or critical habitat designated that may be affected by the action.

3. MAGNUSON-STEVENS FISHERY CONSERVATION AND MANAGEMENT ACT ESSENTIAL FISH HABITAT RESPONSE

Section 305(b) of the MSA directs Federal agencies to consult with NMFS on all actions or proposed actions that may adversely affect EFH. The MSA (section 3) defines EFH as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." Adverse effect means any impact that reduces quality or quantity of EFH, and may include direct or indirect physical, chemical, or biological alteration of the waters or substrate and loss of (or injury to) benthic organisms, prey species and their habitat, and other ecosystem components, if such modifications reduce the quality or quantity of EFH. Adverse effects on EFH may result from actions occurring within EFH or outside of it and may include site-specific or EFH-wide impacts, including individual, cumulative, or synergistic consequences of actions (50 CFR 600.810). Section 305(b) also requires NMFS to recommend measures that can be taken by the Action Agency to conserve EFH. For the purposes of interpreting the definition of EFH, "waters" includes aquatic areas and their associated physical, chemical, and biological properties that are used by fish, and may include areas historically used by fish where appropriate; "substrate" includes sediment, hard bottom, structures underlying the waters, and associated biological communities; "necessary" means habitat required to support a sustainable fishery and a healthy ecosystem; and, "spawning, breeding, feeding, or growth to maturity" covers all habitat types used by a species throughout its life cycle.

This analysis is based, in part, on the EFH assessment provided by the United States Army Corps of Engineers (USACE) and descriptions of EFH for Pacific coast salmon as described in Amendment 18 to the Pacific Coast Salmon Plan (Pacific Fisheries Management Council [PFMC], 2014) contained in the fishery management plans (FMP) developed by the PFMC and approved by the Secretary of Commerce.

The proposed Project area is within the region identified as EFH for Pacific salmon in Amendment 18 of the Pacific Coast Salmon FMP. The USACE is receiving this consultation under the MSA for potential impacts to the EFH of Pacific salmon as a result of implementing the Phase 3 RD 17 Levee Seepage Repair Project (Project) in USGS Hydrologic Unit Code (HUC) 18040003 (San Joaquin Delta).

The PFMC has identified and described EFH, Adverse Impacts and Recommended Conservation Measures for salmon in Amendment 18 to the Pacific Coast Salmon FMP (PFMC 2014). Freshwater EFH for Pacific salmon in the California Central Valley includes waters currently or historically accessible to salmon within the Central Valley ecosystem as described in Myers et al. (1998). Sacramento River winter-run Chinook salmon (Oncorhynchus tshawytscha), Central Valley spring-run Chinook salmon (O. tshawytscha), and Central Valley fall-/late fall-run Chinook salmon (O. tshawytscha) are species managed under the Salmon Plan that occur in the USGS HUCs described in Amendment 18 and occur in the San Joaquin Delta HUC.

3.1 Essential Fish Habitat Affected by the Project

The geographic extent of freshwater EFH is identified as all water bodies currently or historically occupied by Council-managed salmon as described in Amendment 18 of the Pacific Coast Salmon Plan. In the estuarine and marine areas, salmon EFH extends from the extreme high tide line in nearshore and tidal submerged environments within state territorial waters out to the full extent of the Exclusive Economic Zone (EEZ) (200 nautical miles or 370.4 km) offshore of Washington, Oregon, and California north of Point Conception. The proposed Project occurs in the area identified as “freshwater EFH”, as it is above the tidal influence where the salinity is above 0.5 parts per thousand.

The implementing regulations for the EFH provisions of the MSA (50 CFR part 600) recommend that the FMPs include specific types or areas of habitat within EFH as “habitat areas of particular concern” (HAPC) based on one or more of the following considerations: (1) the importance of the ecological function provided by the habitat; (2) the extent to which the habitat is sensitive to human-induced environmental degradation; (3) whether, and to what extent, development activities are, or will be, stressing the habitat type; and (4) the rarity of the habitat type. Based on these considerations, the Council designated five HAPCs: (1) complex channels and floodplain habitats; (2) thermal refugia; (3) spawning habitat; (4) estuaries; and (5) marine and estuarine SAV. No HAPCs occur in the Project area or will be affected by the Project.

3.2 Adverse Effects on Essential Fish Habitat

The proposed Project is considered to have multiple non-fishing activities that affect EFH for Pacific salmon as described in Amendment 18 to the Pacific Coast Salmon FMP. The following actions are considered to have potential adverse effects on the freshwater EFH in the action area of the Project:

1) *Bank Stabilization and Protection* – The proposed Project has components that will entail bank stabilization and protection activities in the action area which includes freshwater EFH. The alteration of riverine and estuarine habitat from bank and shoreline stabilization, and protection from flooding events can result in varying degrees of change in the physical, chemical, and biological characteristics of existing shoreline and riparian habitat. Human activities removing riparian vegetation, armoring, relocating, straightening and confining stream channels and along tidal and estuarine shorelines influences the extent and magnitude of stream bank erosion and down-cutting in the channel. In addition, these actions have reduced hydrological connectivity and availability of off-channel habitat and floodplain interaction. Armoring of shorelines to prevent erosion and maintain or create shoreline real estate simplifies habitats, reduces the amount of intertidal habitat, and affects nearshore processes and the ecology of a myriad of species (Williams and Thom 2001).

2) *Flood Control Maintenance* - The protection of riverine and estuarine communities from flooding events can result in varying degrees of change in the physical, chemical, and biological characteristics of existing shoreline and riparian habitats. Managing flood flows with flood control structures such as levees can disconnect a river from its floodplain eliminating off-channel habitat important for salmon. Floodplains serve as a natural buffer to changes in water flow: retaining water during periods of higher flow and releasing it from the water table during reduced flows. These areas are typically well vegetated, lowering water temperatures, regulating nutrient flow and removing toxins. Juvenile salmon use these off channel areas because their reduced flows, greater habitat complexity and shelter from predators may increase growth rates and their chance of survival. Artificial flood control structures have similar effects on aquatic habitat as does the efforts to stabilize banks and remove woody debris. The function of natural

stream channels and associated riparian areas and the effects of flood control structures such as levees has been discussed in section 2.5.1.5 of this biological opinion.

3) *Wetland and Floodplain Alterations* – Pacific salmon evolved in the Central Valley with an extensive and complex floodplain adjacent to the river, with many channels and sloughs dissecting the plain and extensive wetlands and marshes fringing the waterways. Most of these floodplains and associated wetlands and marshes have been lost to anthropogenic causes. Floodplains, including side channels, and wetlands throughout the region have been converted through diking, draining, and filling to create agricultural fields, livestock pasture, areas for ports, cities, and industrial lands. The construction of dikes, levees, roads, and other structural development in the floodplain that confine the river have further effects on salmon habitat (PFMC 2014). As described in Amendment 18, a river confined by adjacent development and/or flood control and erosion control structures, can no longer move across the floodplain and support the natural processes that 1) maintain floodplain connectivity and fish access that provide velocity refugia for juvenile salmon during high flows; 2) reduce flow velocities that reduce streambed erosion, channel incision, and spawning redd scour; 3) create side channels and off-channel areas that shelter rearing juvenile salmon; 4) allow fine sediment deposition on the floodplain and sediment sorting in the channel that enhance the substrate suitability for spawning salmon; 5) maintain riparian vegetation patterns that provide shade, large wood, and prey items to the channel; 6) provide the recruitment of large wood and spawning gravels to the channel; 7) create conditions that support hyporheic flow pathways that provide thermal refugia during low water periods; and 8) contribute to the nutrient regime and food web that support rearing and migrating juvenile salmon in the associated mainstem river channels.

3.3 Essential Fish Habitat Conservation Recommendations

The USACE should implement the following conservation measures to offset the adverse effects described in section 3.2 above. In order to avoid or minimize the effects to EFH, NMFS recommends the following conservation measures described in Amendment 18 to the Pacific Coast Salmon FMP:

1) *Bank Stabilization and Protection*

- Minimize the loss of riparian habitats as much as possible.
- Bank erosion control should use vegetation methods or “soft” approaches (such as beach nourishment, vegetative plantings, and placement of IWM) to shoreline modifications whenever feasible. Hard bank protection should be a last resort and the following options should be explored (tree revetments, stream flow deflectors, and vegetative riprap.
- Re-vegetate sites to resemble the natural ecosystem community.
- Replace in-stream fish habitat by providing root wads, deflector logs, boulders, rock weirs and by planting shaded riverine aquatic cover vegetation.
- Use an adaptive management plan with ecological indicators to oversee monitoring and ensure mitigation objectives are met. Take corrective action as needed.

- Implement term and conditions 1(a-e), from the section 7 Opinion for this Project.

2) *Flood Control Maintenance*

Include the conservation measures from the *Bank Stabilization and Protection* section of the Opinion and:

- Retain trees and other shaded vegetation along earthen levees and outside levee toe.
- Ensure adequate inundation time for floodplain habitat that activates and enhances near-shore habitat for juvenile salmon.
- Reconnect wetlands and floodplains to channel/tides.

3) *Wetland and Floodplain Alterations*

- Minimize alteration of floodplains and wetlands in areas of salmon EFH.
- Determine cumulative effects of all past and current floodplain and wetland alterations before planning activities that further alter wetlands and floodplains.
- Promote awareness and use of the USDA's wetland and conservation reserve programs to conserve and restore wetland and floodplain habitat.
- Promote restoration of degraded floodplains and wetlands, including in part reconnecting rivers with their associated floodplains and wetlands and invasive species management.

Fully implementing these EFH conservation recommendations would protect, by avoiding or minimizing the adverse effects described in section 3.2, above, approximately 26,000 linear feet of shoreline of designated EFH for Pacific coast salmon along the San Joaquin River,

3.4 Statutory Response Requirement

As required by section 305(b)(4)(B) of the MSA, the USACE must provide a detailed response in writing to NMFS within 30 days after receiving an EFH Conservation Recommendation. Such a response must be provided at least 10 days prior to final approval of the action if the response is inconsistent with any of NMFS' EFH Conservation Recommendations unless NMFS and the Federal agency have agreed to use alternative time frames for the Federal agency response. The response must include a description of measures proposed by the agency for avoiding, minimizing, mitigating, or otherwise offsetting the impact of the activity on EFH. In the case of a response that is inconsistent with the Conservation Recommendations, the Federal agency must explain its reasons for not following the recommendations, including the scientific justification for any disagreements with NMFS over the anticipated effects of the action and the measures needed to avoid, minimize, mitigate, or offset such effects (50 CFR 600.920(k)(1)).

In response to increased oversight of overall EFH program effectiveness by the Office of Management and Budget, NMFS established a quarterly reporting requirement to determine how many conservation recommendations are provided as part of each EFH consultation and how many are adopted by the Action Agency. Therefore, we ask that in your statutory reply to the EFH portion of this consultation, you clearly identify the number of conservation recommendations accepted.

3.5 Supplemental Consultation

The Corps must reinitiate EFH consultation with NMFS if the proposed action is substantially revised in a way that may adversely affect EFH, or if new information becomes available that affects the basis for NMFS' EFH Conservation Recommendations (50 CFR 600.920(l)).

4. DATA QUALITY ACT DOCUMENTATION AND PRE-DISSEMINATION REVIEW

The Data Quality Act (DQA) specifies three components contributing to the quality of a document. They are utility, integrity, and objectivity. This section of the opinion addresses these DQA components, documents compliance with the DQA, and certifies that this opinion has undergone pre-dissemination review.

4.1 Utility

Utility principally refers to ensuring that the information contained in this consultation is helpful, serviceable, and beneficial to the intended users. The intended users of this opinion are the USACE. Other interested users could include the USFWS, CDFW, and DWR. Individual copies of this opinion were provided to the Corps and USFWS. This opinion will be posted on the Public Consultation Tracking System Website. The format and naming adheres to conventional standards for style.

4.2 Integrity

This consultation was completed on a computer system managed by NMFS in accordance with relevant information technology security policies and standards set out in Appendix III, 'Security of Automated Information Resources,' Office of Management and Budget Circular A-130; the Computer Security Act; and the Government Information Security Reform Act.

4.3 Objectivity

Information Product Category: Natural Resource Plan

Standards: This consultation and supporting documents are clear, concise, complete, and unbiased; and were developed using commonly accepted scientific research methods. They adhere to published standards including the NMFS ESA Consultation Handbook, ESA regulations, 50 CFR 402.01 et seq., and the MSA implementing regulations regarding EFH, 50 CFR 600.

Best Available Information: This consultation and supporting documents use the best available information, as referenced in the References section. The analyses in this opinion and EFH consultation contain more background on information sources and quality.

Referencing: All supporting materials, information, data and analyses are properly referenced, consistent with standard scientific referencing style.

Review Process: This consultation was drafted by NMFS staff with training in ESA and MSA implementation, and reviewed in accordance with West Coast Region ESA quality control and assurance processes..

The annnual Sacramento River runoff at Red Bluff is on average nearly four times greater than the San Joaquin River at Millerton. Temporal differences in the pattern of runoff of the two rivers is due to differences in the amount of precipitation received as rain (dominant on the Sacramento), versus snow (dominant on the San Joaquin) and differences in underlying geology. The lower graph also plots the pattern of Central Valley precipitation to illustrate how precipitation and runoff are out of phase.

Data from California Department of Water Resources.

Sacramento, CA 95814

Subject: Biological Opinion on Phase 3 of the Reclamation District 17 Levee Seepage Repair Project

Dear Mr. Ziminske:

This is in response to your letter requesting formal consultation with the U.S. Fish and Wildlife Service (Service) for Phase 3 of the Reclamation District 17 (RD 17) Levee Seepage Repair (project). At issue are the effects of the proposed project on the federally listed valley elderberry longhorn beetle (*Desmocerus californicus*) (beetle) and riparian brush rabbit (*Sylvilagus bachmanni riparius*) (rabbit). Your request was received on August 21, 2018. This response is provided under the authority of the Endangered Species Act of 1973, as amended (16.U.S.C. 1531 *et seq.*) (Act).

The Federal action on which we are consulting is the Corp of Engineers' (Corps) issuance of a combined Section 404 and Section 10 Department of Army permit and Section 408 permission to RD 17 for alterations of a Federal project, specifically, within the RD 17 levee system. The scope of this Biological Opinion (BiOp) includes emergency construction done in 2017 as a result of the volume and duration of flooding that year, and additional remaining work to be done to complete construction. The findings in this consultation are based on the Biological Assessment (BA) included with your letter, discussions and communications with Corps staff, and other information in our files.

Consultation History

May 14, 2010: Memorandum with attached preliminary wetland delineation from RD 17's consultant (AECOM) to the Service requesting technical assistance on the effects of the project to listed species, noting the need to remove vegetation on both sides of the project levees to comply with Corps vegetation management standards.

January 24, 2011: Service staff (Hansen, Schoenberg) meet with RD 17 consultant AECOM (Holland-Fitzgerald, Lehman) to discuss comments on draft Biological Assessment; included a presentation of habitat impacts (map and tabular summary).

March 1, 2011: Service staff (Schoenberg) attends a site visit to the project area.

September 13, 2011: Draft Environmental Impact Statement/Environmental Impact Report (DEIR/S) on the project is received.

October 24, 2011: Service transmits a comment letter on the DEIR/S, noting effects of maintenance, limited setbacks, effects on dispersal habitat for the listed rabbit, potential underestimation of habitat effects, growth-inducing effects, uncertainty regarding any variance request, and other remarks.

July 9, 2014: Email exchange; Service staff respond to Corps request regarding distance of the project to giant garter snake location records.

April 6, 2015: Service receives Corps' March 27, 2015, request for formal consultation on the project; the enclosed February 2015 BA indicates that, under the Corps interim policy dated March 21, 2014, waterside vegetation would be managed in accordance with RD 17 existing practices.

October 2, 2015: Service transmits a letter requesting additional information on current and future waterside maintenance, listed species habitat effects and compensation, management/monitoring of setback element IVc, future flood control projects, and other on-site compensation opportunities.

June 3, 2016: Service receives the Final Environmental Impact Report (FEIR) for the project including responses to Service comments (FEIR pp. B38-B43; also referencing pp. B1-B2). Therein, RD 17 states a preferred alternative to retain waterside slope vegetation.

March 13, 2017: Service receives the Corps' March 8, 2017, request for formal consultation; the enclosed revised BA dated February 2017 includes clarifications and responses to our additional information request, and an updated description of the proposed action. The revised BA (p. 18) states that RD 17 is not considering full compliance with the Corps' Engineering Technical Letter standards as an alternative because the requester of Section 408 permission is not required to bring portions of an existing project that are not impacted by an alteration up to Corps standards. Landside vegetation would be cleared from work areas, but no waterside woody or riparian vegetation would be removed. Long term vegetation management would be a continuation of current practices to maintain access and visibility.

March 22, 2017: Corps (Ha) transmits an email informing Service of receipt of a Regional General Permit #8 Emergency Action notification for RD 17 emergency construction project and requests comments (permit request and supportive materials provided).

March 23, 2017: Service (Kline) transmits an email responding to the Corps' March 22, 2017, email request for comments on emergency construction, recommending a 100-foot buffer around elderberry shrubs or transplantation to avoid effects on the beetle, and daytime work to avoid effects on the rabbit.

April 4, 2017: Corps issues a letter to RD 17 approving emergency work permit request.

January 12, 2018: Corps (Lee) emails the Service a request to review a conceptual mitigation/monitoring plan.

February 27, 2018: Service (Schoenberg) emails comments on the conceptual mitigation/monitoring plan.

August 21, 2018: Service receives Corps letter requesting formal consultation and a second revised BA dated May 2018; it identifies 3.31 acres of effects to landside woodlands suitable as rabbit habitat and states that 1.61 acres of such habitat were removed through emergency action.

November 30, 2018: Meeting of the Service, RD 17, Corps, and consultants (GEI, KSN) to discuss this consultation, responses to the information request, work done and remaining, and any further needs. The consultants provide exhibits showing locations and types of work done during emergency and remaining, as-built footprints where grading had occurred, and a conceptual planting plan for the setback mitigation area. Service requests a tabulation of impacts by cover type, emergency and remaining, for the project elements.

December 3, 2018: Service emails the Corps a request to clarify construction schedule and best estimate of timeframe for acquisition of lands for proposed setback levee/floodplain restoration element.

December 17, 2018: Corps transmits the requested tabulation of habitat impacts, showing the 3.31 acres of rabbit habitat and other cover types affected or to be affected by the project.

December 19, 2018: Corps forwards the consultants' response to requested clarification of construction schedule (i.e., 3 seasons for project [2019-2021], 2 for setback [no year specified]).

February 7, 2019: Corps forwards the consultants' response to the requested clarification of setback area acquisition schedule (i.e., RD 17 is moving forward with and is 100% committed to acquisition [no year indicated]).

March 14, 2019: Service transmits a draft BiOp project description for Corps review.

March 22, 2019: Corps transmits comments on the draft BiOp project description.

April 2, 2019: Phone communication between Service (Schoenberg) and Corps staff (Toland), The Corps clarifies construction sequencing, requiring existing elderberries to be transplanted to a bank rather than in the setback area, and that additional elderberry plantings would be included in the setback area after completion of element IVc and site preparation.

BIOLOGICAL OPINION

Description of the Action

The proposed project involves a third phase of intermittent work totaling 5.3 miles of the levee along the right (east) bank of the San Joaquin River bordering Reclamation District 17 (RD 17). This border of RD 17 extends from French Camp Slough, about 3 miles south of the city center of Stockton, south to Walthall Slough. The purpose of the project is to correct seepage deficiencies needed to meet current Corps standards. Nearly all of the work that has been done or will be done in all phases is considered "in place" and is almost entirely on the landside of existing levees. Phase I, completed in 2009, involved constructing seepage berms in elements III and VI; phase II, completed in 2010, was construction of drained seepage berms in 8 reaches and maintenance/cleanup at a 9th reach; phase III - the subject of this consultation - encompasses 19 elements, and would involve constructing a combination of seepage berms, chimney drains, cutoff walls, a landside grade raise, and a setback levee which includes limited waterside work to the existing levee. Appendix 1 (Figures) includes the location of work sites and cover types (Figures 1a-c), conceptual-level detail for the compensation site (Figure 2), schematics of the basic work types (Figures 3a-g), and locations of known elderberry shrubs (Figure 4). The basic work types and specific locations are described below.

Seepage Berm

A drained seepage berm is a structure built on the landside of a levee consisting of layers of sand filter material, drain rock, filter fabric, and soil fill (Figure 3a). It works by collecting and conveying seepage that moves under the levee and then away from the levee ("under seepage"), and reducing the potential for boils, piping, and failure. It is sized based on the underlying soil permeability and expected pressure head during high water. For the proposed project, berm widths of 60-120 feet are expected to be adequate. Some seepage berms have a toe drain (e.g., in element VIIg), which is an additional element at the landward margin of the seepage berm consisting of a below-grade perforated pipe surrounded by a trench filled with sand and drain rock (Figure 3b). This is used to collect and convey seepage water away from the berm.

Chimney Drain

A chimney drain collects and conveys seepage that flows through the levee itself ("through seepage"). It consists of a 1-3 foot thick layer of sand and drain rock placed against the lower landside slope of the levee, with filter fabric between the soil and rock layers. A layer of levee fill material is then keyed in over the levee slope and chimney drain, widening the levee landside. The chimney drain rock is tied into the existing or new seepage berm drain rock (Figure 3c).

Cutoff Wall

Cutoff walls are proposed for selected project locations. A cutoff wall involves installing a vertical layer of impermeable material (usually bentonite clay or bentonite/cement mixture) through the levee and underlying permeable soils as needed until low-permeability foundational soils are reached. Cutoff walls will intercept both under and through seepage. Two methods are used depending on the depth of foundational soils. The conventional open-trench method is used for depths up to 80 feet, and involves removing the top third to half of the levee height, excavating a trench, filling the trench with bentonite slurry, and rebuilding the removed portion with a cap of levee fill material (Figure 3d). The deep slurry mixing method can install cutoff walls up to 120 feet deep without degrading the levee crown (Figure 3e). Specialized equipment is used to excavate into the subsurface and mix soil in place with cement or bentonite. For the RD 17 phase III project, cutoff walls would overlap seepage berms by 300 feet, and slopes would be modified with added fill to achieve a 20-foot crown width and 3:1 landside slope.

Setback Levee

A setback levee is a levee which is built some distance to the landside of an existing levee. The proposed action includes a 1,100-foot-long setback levee in element IVc, portions with either a seepage berm or cutoff wall (Figures 3f-g). The setback levee would tie into the existing levee at the upstream and downstream ends. To accomplish the tie-in, the top one-third to one-half of the existing levee would be degraded, beginning with a 1:1 cut at the existing waterside crown. Where the existing levee intersects the new setback levee, the waterside of the existing levee above the high tide line would be stabilized with approximately 0.64 acres (740 linear feet) of riprap. The riprap would be handplaced around any trees/shrubs. Once the new setback levee is complete and certified, 400 linear feet of the existing levee above the high tide line would be removed to allow inundation of the expanded land in the floodway.

Floodplain Restoration

After the setback levee is complete, restoration of the oxbow area separated by the setback levee would proceed (Figure 2). About 400 linear feet of the existing levee above the high tide line on the downstream side of the oxbow would be degraded to a to-be-decided level to allow floodwater inundation (probably around 10 feet North American Vertical Datum). Some site preparation may be done such as grading, excavation, and/or ripping of the existing levee or other surfaces. It would be designed to drain after high water events. The existing levee would be planted with trees, shrubs (including blue elderberry), and herbs to create oak riparian forest habitat, the swale planted with wetland herbs, and the remainder of the site planted with a riparian scrub pallette. The current plan is conceptual and subject to refinement. A range of 9.9-11.1 acres combined of riparian forest (maximum 5 acres) and riparian scrub (maximum 6.1 acres) habitats will be restored, and is considered a compensation measure for effects to the beetle and rabbit.

Raise Landside Grade

At one site in element Ib, a 5-foot-deep depression next to the landside toe would be raised with fill.

A number of additional activities are considered as part of the proposed project, specifically:

- **Levee geometry corrections:** Fill material would be placed along the landside of existing levee slopes where needed to provide the minimum 3:1 slope and a minimum 20-foot-wide levee crown. All elements require some level of levee geometry correction.
- **Operations and Maintenance (O&M) access and utility corridors:** A 20-foot-wide permanent O&M access corridor would be established adjacent to the landside toe of seepage berms and levees (if not already present for levees). Any relocated power poles and other utility infrastructure would be located outside this easement.
- **Temporary construction easements:** Where needed, a 20-foot-wide temporary construction easement and construction turnaround area (up to 80 feet in diameter) would be included adjacent to the inland side of the permanent O&M access corridor, to provide access to the site during construction. These features would be removed and the site(s) would be returned to pre-project conditions following completion of construction.
- **Stormwater /irrigation controls:** Drainage/irrigation swales would be constructed around the outside boundaries of levee repairs, where needed, and other stormwater best management practices would be implemented to manage stormwater runoff and/or irrigation during and after construction. These swales would be located so that they would not drain to/from wetlands or other waters of the United States.
- **Right-of-way acquisition:** Lands within the project footprint would be acquired as needed, to accommodate levee repairs (e.g., seepage berms, setback levees) and establish the minimum 20-foot-wide O&M access corridor at the landside toes of all the improved levees, to prevent encroachment. Privately owned lands would be acquired in fee preferably, but may be taken as easements if needed. Where the project footprint overlies land owned and managed by other agencies (i.e., the City of Lathrop, San Joaquin County, Union Pacific Railroad), either the land would have to be acquired in fee or easements would have to be obtained and secured.
- **Hauling:** An estimated 700,000 cubic yards of imported material (i.e., soil, aggregate, and cement) would be used in construction. Materials would be hauled to the work sites from commercial sources up to 11 miles away. Personnel, equipment, and imported materials would be transported to the Phase 3 Repair Project area using various surface roads that connect with Interstate 5 or State Route 120. The primary corridors where construction activity would take place would be public roadways, on and within 300 feet of the levees, on existing unpaved roads used for access to work areas, and on levee patrol roads atop the levee crown.
- **Vegetation removal:** Landside vegetation within the footprint of the proposed levee work, including maintenance roadway corridors and temporary access easements, would be removed to prepare for levee repair work. Any elderberry shrubs that cannot be avoided will be transplanted, either to the setback area or to an approved mitigation bank, which is considered a compensation measure for effects to the beetle. The proposed action would involve performing limited work on the waterside of the levee above the high tide line (e.g., installing riprap and degrading a portion of the existing levee in element IVc where a setback levee would be constructed). However, no waterside

woody or riparian vegetation would be removed; the areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Encroachment management:** Several features, including power poles, vegetation, and a variety of agricultural-related facilities (e.g., irrigation infrastructure, fences), are within the Phase 3 Repair Project footprint. Utility infrastructure would be relocated as needed to accommodate the levee repairs, and any pipelines or other underground utility crossings would be replaced as needed. Other encroachments in the Phase 3 Repair Project area would be removed or relocated as required to meet the criteria of the Corps, the Central Valley Flood Protection Board, and the Federal Emergency Management Agency. No waterside woody or riparian vegetation would be removed. Areas where riprap would be placed and the levee degraded are characterized by ruderal land cover.

- **Long-Term Vegetation Management:** Vegetation on the levees and within the access easements would be managed by RD 17 continuing its current O&M practices to maintain access and visibility. These practices include: mechanical trimming of existing trees and removal of large dead and downed trees annually; regular summer and winter application of herbicides for weed control; and summer application of berbicides to control woody plants and berries. The zone where trees would be trimmed includes the levee prism on both landside and waterslide slopes, and beyond the levee prism within 15 feet of the landside and waterside toes. The vertical extent of trimming would be from the ground up to 5 feet above the ground (except roads), and from the surface up to 12 feet above the crown road. Trees would be trimmed only and not removed. However, no waterside or landside vegetation outside of the project footprint would be removed because of future vegetation management activities (BA p. 56; see Effects, below, for details).

Conservation Measures

The following general, avoidance and minimization, and compensation measures shall be implemented:

General

- A qualified biologist will be on-site to ensure compliance with these measures.

- A worker awareness training program will be conducted for construction crews before start of construction, including an overview of special-status species and sensitive resources (including riparian habitats) in the project area, measures to avoid and minimize effects on these resources, and conditions of relevant regulatory permits.

- Vehicle speeds on unpaved surfaces will be limited to 15 miles per hour.

Valley Elderberry Longhorn Beetle

Avoidance and Minimization Measures

- Elderberry shrubs near construction areas that can be avoided will be protected by temporary fencing 20 feet from the shrub dripline where possible; if closer than 20 feet, k-rails will be placed at the shrub dripline. This will be done before any constuction. Fences will be inspected weekly during construction.

- No insecticide/herbicide/chemicals that could harm the beetle or its host plant will be used within 100 feet of elderberry shrubs.

- Where avoidance is not possible elderberry shrubs will be transplanted to a Service approved site from November 1 - February 15 only.[1]

- Elderberry shrubs affected by transplantation and any associated riparian habitat that would be removed will be replaced by additional plantings to the levee setback area in element IVc.

Compensation Measure

- RD 17 proposes to offset the impacts from the removal of 3.28 acres of landside riparian vegetation considered beetle habitat and the transplantation of associated elderberry shrubs with stems >1 inch, with the creation of at last 9.9 acres (and up to 11.1 acres) of riparian forest and riparian scrub habitat within a setback area created by construction of element IVc. The restoration design would include elderberry seedlings and associated species plantings.

Riparian Brush Rabbit

Avoidance and Minimization Measures

- Potential rabbit habitat will be identified and avoided whenever possible. Contractors will coordinate with a Service-approved biologist to ensure that construction will minimize disturbance to rabbit habitat to the extent feasible.

- Temporary fencing will be installed to prevent disturbance of potential rabbit habitat adjacent to construction areas, and construction personnel, vehicles, and equipment will not enter these areas. In addition, a silt fence or other suitable temporary barrier (either incorporated into the temporary fence, or separate) will be installed to deter entry of

[1] The specified location for transplants in the BA (p. 54) is the setback area created by element IVc, however, that area may not be available to accept transplants if construction sequencing requires removal of elderberries before element IVc and other setback area site preparations including grading are complete. In that circumstance, this project description assumes transplanting the affected shrubs to a Service-approved mitigation bank.

rabbits into construction areas. Signage will be posted warning workers to stay within construction areas and outside of habitat. The fencing, barrier, and signage will be removed after work is completed.

- If rabbit habitat must be removed, it will be done by hand 2 weeks before construction, and overseen by a qualified biologist. Areas of temporary disturbance will be revegetated with native plants and restored to pre-project conditions.

Compensation Measure

- RD 17 proposes to offset the effect of removal of 3.31 acres of landside riparian vegetation considered rabbit habitat by the restoration of at least 9.9 acres (and up to 11.1 acres) of riparian habitats within the setback area of construction element IVc.

Emergency and remaining work by location:

At those elements where a cutoff wall was not indicated, some or all of the seepage berm part of construction was installed during emergency work in 2017. However, these emergency sites all require additional work to complete (chimney drains, levee fill material, and/or remaining seepage berms). No work has yet been done at sites with cutoff walls, chimney drains only, setback levee, and at one seepage berm site. Table 1 shows the proposed work for each site, emergency work done in 2017, and remaining work to be done, for each element location.

Construction Schedule

The emergency work was done from February-November, 2017. The remaining construction is expected to span up to 3 seasons, starting in May 2019; two seasons may be sufficient and a third season is included for contingency purposes. Actual levee work is seasonal (July 1 - November 1), however, variances outside this window may be requested and approved, and there is other work such as utility relocation which could be done outside this window. The setback levee and floodplain restoration, which is a compensation measure, would take two seasons to complete. The construction sequence includes advance work involving relocation of power poles, site preparation (including vegetation removal and elderberry shrub relocation), and removal of landside structures.

Action Area

The action area is defined in 50 CFR §402.02, as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action." For the proposed project, this means all areas directly or indirectly affected by construction of the 19 elements of the proposed RD 17 phase 3 project, including the levee work, the floodplain created by the setback levee, and the subsequent long term vegetation management as defined in the project description of this BiOp.

Table 1. Comparison of all Major RD 17 Phase 3 Levee Repair Project Features with Those Features Completed as Emergency Actions in 2017 and Those Features Remaining to be Completed (and which are the subject of this consultation)

Element	Type of Remediation	Phase 3 Project Major Features	Phase 3 Project Features Constructed as 20-17 Emergency Response Actions	Phase 3 Project Features Remaining To be Constructed
Ia	under seepage and through seepage	Construct approximately 590 feet of seepage berm (approximately 110 feet wide) and approximately 590 feet of chimney drain to meet required exit gradients. Construct PG&E high voltage tower footing raisings. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.	Constructed approximately 350 feet of seepage berm to meet required exit gradients. The constructed seepage berm width is approximately 110 feet.	Construct approximately 240 feet of additional seepage berm (approximately 110 feet wide) and approximately 590 feet of chimney drain to meet required exit gradients. Construct PG&E high voltage tower footing raisings. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.
Ib	under seepage and through seepage	Fill existing depression to approximately 300 feet from toe of existing levee. Construct approximately 130 feet of seepage berm (approximately 80 feet wide) and approximately 130 feet of chimney drain on top of fill to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.	Filled existing depression to approximately 300 feet from toe of existing levee. Constructed approximately 130 feet of seepage berm on top of fill to meet required exit gradients. The constructed seepage berm width is approximately 80 feet.	Construct approximately 130 feet of chimney drain to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.
Ie	under seepage and through seepage	Construct approximately 590 feet of seepage berm (approximately 70 feet wide) and approximately 590 feet of chimney drain to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.	Constructed approximately 590 feet of seepage berm to meet required exit gradients. The constructed seepage berm width is approximately 70 feet.	Construct approximately 590 feet of chimney drain to meet required exit gradients. Place levee fill material along landside of existing levee slope where needed to provide minimum 3:1 slope and 20-foot levee crown width.

Analytical Framework for the Jeopardy Determination

Section 7(a)(2) of the Act requires that Federal agencies ensure that any action they authorize, fund or carry out, is not likely to jeopardize the continued existence of listed species. "Jeopardize the continued existence of..." means to engage in an action that would reasonably be expected, either directly or indirectly, to appreciably reduce the likelihood of both the survival and recovery of a listed species in the wild by reducing reproduction, numbers, or distribution of that species (50 CFR §402.02).

The jeopardy analysis in this biological opinion considers the effects of the proposed Federal action and any cumulative effects on the rangewide survival and recovery of the listed species being consulted on. There are four components of this analysis for each species: (1) the *Status of the Species*, which evaluates the species' range-wide condition, the factors responsible for that condition, and its survival and recovery needs; (2) the *Environmental Baseline*, which evaluates the condition of species in the action area, the factors responsible for that condition, and the relationship of the action area to the survival and recovery of the species; (3) the *Effects of the Action*, which determines the direct and indirect impacts of the proposed Federal action and the effects of any interrelated or interdependent activities on the species; and (4) *Cumulative Effects*, which evaluates the effects of future, non-Federal activities in the action area on the species.

Status of the Valley Elderberry Longhorn Beetle

The Service designated the beetle as threatened and proposed critical habitat on August 8, 1980 (Service 1980) and approved a final Recovery Plan on June 28, 1984 (Service 1984). This wood-boring beetle is a subspecies of the California elderberry longhorn beetle, which persists in small isolated populations in the California Central Valley in riparian areas which have a component of elderberry savannah. The listed subspecies is typified by sexual dimorphism, in which the male shows a predominantly red elytra. The primary threat to the species is habitat loss, particularly along major river systems that are known to bave supported the species, often as a result of urban or agricultural development and flood control actions (both construction and operation and maintenance). Additional major threats are that of extinction due to small population size, predation from alien species such as the Argentine ant, inadequate protections (other than the Endangered Species Act), pesticides, non-native plants of various types that compete with native riparian vegetation including elderberries, and other factors. The beetle itself is rarely seen, and the vast majority of its detections reported in the California Natural Diversity Database have been inferred from the presence of exit holes in host elderberry plant stems.

The period since the beetle's listing to the present has witnessed considerable population and urban growth in California at the expense of remaining riparian habitat and adjacent upland habitat near river systems that supported elderberry. Elderberry plants can colonize and persist on levees and nearby lands as well, and some beetle and exit hole records have been reported in this type of habitat. In floodways, this form of habitat is often the result of deferred maintenance. However, Federal flood control improvements including the currently proposed project, as well as State-wide initiatives to improve the standard of flood control in urban systems generally, have resulted in levee improvements and more rigorous maintenance that has limited floodway habitat. Mitigation for beetle habitat losses is typically done off-site in mitigation or conservation banks, and habitat enhancement has been almost entirely limited to Federal and State refuge lands in the north Central Valley. Since its 1980 listing continuing to the present time, there has been a progressive further decline in beetle habitat amount and distribution with increasing discontinuity between remaining habitat fragments, reduced frequency of sightings, and likely curtailment of the range of this species.

Valley Elderberry Longhorn Beetle Environmental Baseline in the Action Area

Most of the records of adult beetles date from the 1980s and 1990s or earlier. With the exception of recent pheromone trials on a Service refuge that yielded ~20+ captures in 2014, only about a dozen other beetle specimens have been seen anywhere in the last 15 years, and the majority of these were in conservation areas on Federal or State lands or conservation banks in the North Central Valley. The nearest to the proposed projectis a sighting of adult beetles (including a male) in 1984 from Middle River, <4 miles west of project element Va. In the region of the proposed project, there were several beetle exit holes detected along the Calaveras River and Bear Creek 15-20 miles northeast of the project area. Upon re-examination in 1989 by Barr (1991), these particular vicinity locations no longer supported beetles nor live elderberry plants. Occasional exit holes have been seen in elderberry plants along the Stanislaus River 12-20 miles to the southeast of the project area as well. Other studies of formerly occupied areas of both South and North Central Valleys have shown complete loss of elderberry plants, negative surveys for beetle holes, or very low occupancy (Collinge et al. 2001; Kucera et al. 2006; River Partners 2007; Holyoak and Graves 2010).

The project area includes potential habitat for the species which will be affected by the proposed action, but no critical habitat. Patches of riparian vegetation are present in scattered, limited amounts, throughout the project area, depending on the extent and intensity of maintenance of the current levees. A total of 18 elderberry shrubs, none with exit holes, were observed during surveys of project reaches in 2011 and 2014, of which there were 9 shrubs on the land side that would be affected by project construction (Figure 4). Eight of these elderberry shrubs to be affected have stems greater than 1 inch diameter (in elements IVa, IVc, and V-VIa.1). The presence of elderberry shrubs, their location in or near riparian habitats, and records of beetles or exit holes in the region lead us to conclude that the beetle is present in the project area.

Status of the Riparian Brush Rabbit

The Service designated the rabbit as endangered on February 23, 2000 (Service 2000) and included it in a final Recovery Plan for upland species on September 30, 1998, which preceded the listing decision (Service 1998). We have since drafted a 5-year review which is not yet published (Service 2012), but was used for this BiOp to update this narrative of the status of the species. It is a medium-to-small cottontail with a relatively pale color, distinguishable from other species and subspecies by its outwardly protruding cheeks, smaller tail, and uniformly colored ears. It lives in riparian communities of willow thickets, California wild rose, Pacific blackberry, and other shrubs and grasses. Habitat components of suitable rabbit habbit include large patches of dense brush, ecotonal edges of grass and forbs next to brushy cover, scaffolding plants for the blackberry and rose to grow tall enough to withstand flood events, an open overstory (if trees are present), and vegetated high-ground to surve as flood refugia. There are three population centers: Caswell Memorial State Park (MSP), a fragmented metapopulation in the South Delta on both sides of the San Joaquin River that includes the proposed project area and Paradise Cut, and a new population within San Joaquin River National Wildlife Refuge (NWR) established by the release of captive-bred individuals. Population size at these centers varies widely from a few individuals to perhaps several hundred, with very few individuals being trapped recently at Caswell MSP. The two natural populations (Caswell MSP and South Delta) show substantial genetic differentiation, while rabbits in other locations (South Delta, east compared to west sides of the San Joaquin River) were not distinct from each other.

The primary threat to the rabbit is habitat loss, originally through the widespread destruction of riparian forest which greatly reduced its range, and continuing today through various activies such as levee maintenance, fire-hazard maintenance, and urban development, all of which further reduce and/or preclude the restablishment of habitat. A variety of other natural and manmade factors also threaten the rabbit, particularly severe flooding (especially in the absence of adequate high water refugia), and effects of small population size (e.g., inbreeding, genetic drift, local extinction events), but also predation (including feral cats and dogs), pesticides, competition and climate change. The combination of small population size, restricted distribution, fluctuation of numbers, and extreme level of threat lead us to conclude that the species remains at a high risk of loss of genetic diversity and extinction at this time.

The remaining range of the rabbit is subject to periodic flooding during wet years and especially from longer-duration snowmelt flooding. Post-flood surveys conducted in Caswell MSP and the San Joaquin NWR since listing indicate high mortality of rabbits from floods; populations can rebound after the flood, but this did not happen in Caswell MSP after consecutive floods in the 1990s. At the refuge, the rabbits were wiped out by the 2006 flood, restored only by additional captive-bred released individuals together with creation of refugia mounds. Although there have been very few rabbit captures from the South Delta population, the regularity of such captures before and after flood events suggests persistence, possibly as a consequence of adequate high water refugia such as existing levees and woody vegetation which the rabbits can climb.

Riparian Brush Rabbit Environmental Baseline in the Action Area

In the region, there are 20+ known observations of the rabbit along the San Joaquin River from about De Lima Road south to Paradise Cut, which includes the project area, and along Paradise Cut itself to the south and west of the project area, generally from the early 2000s and later. In the immediate vicinity of work sites of the project, trapping in 2003 and 2004 detected rabbits adjacent to elements IIIa and IIIb, and between elements Va-VIa.1 and V1a.4 where there is an oxbow with a significant patch of rabbit habitat between these two work elements. Similar habitat is present adjacent to elements IIab, IVc, and Va-VIa.1. The presence of small patches of rabbit habitat in the form of riparian scrub in several project elements, relatively recent and repeated records of rabbit captures within the project area, and potential for rabbits to disperse along the levee margin, lead us to conclude that the rabbit is present in the project area.

Effects of the Proposed Action

Valley Elderberry Longhorn Beetle

Habitat for the beetle will be directly affected by removal of elderberry bushes during construction and maintenance of the project. Beetle habitat consists of elderberry bushes as well as associated riparian plants. An estimated 9 existing bushes, 8 with stems >1 inch diameter, would need to be removed and transplanted elsewhere because they are within the construction footprint or maintenance easements (Figure 4). The emergency response work did not result in effects to the beetle because no elderberry shrubs were within 100 feet of project activities. For the remaining work, shrubs would only be transplanted from November 1 to February 15. Any work scheduled for the remainder of the 2019 construction season, before transplantation, would avoid impacts by staying at least 100 feet away from elderberry shrubs.

A total of 4.04 landside acres of riparian woodland, including the 9 elderberry plants, would be removed by project activities (Table 2; sum of totals for Great Valley Cottonwood Riparian and Great Valley Oak Riparian Forest). Of this, 1.95 acres has already been affected by emergency action, mostly through the construction of seepage berm in elements IIIb-IVa. This 1.95 acres of loss did not remove elderberry plants, but did affect the beetle through its removal of riparian woodland associated with elderberry plants. Another 2.09 acres, including the aforementioned elderberry plants, will be affected by future activities beginning in 2019, primarily through the construction of cutoff wall and levee fill placement in element Va-VIa.1.

The BA (p.54) notes that 3.03 acres of riparian habitat associated with elderberry plants would be removed due to the project in elements IIIa, IIIb, IVa, and Va-V1a.1, but did not provide reasoning for exclusion of riparian impacts in other elements, and this total did not precisely match the total for these elements provided later (2.99 acres; Table 2). It may be that the Corps considered some riparian to the north (elements 1a-b, fragments of natural scrub) and south (elements VIIe-g; oak trees) less likely to support beetles due to a fragmented nature, absence of elderberries, and/or distance or disconnection between those fragments and the areas with elderberries. Nevertheless, fragmentation is typical of the regional landscape, and the distance from the excluded elements to other elderberries (1-2 miles) is not so great as to preclude their occurrence at some point in the project life, or use by beetles. Our 2017 Framework did not provide specific distances or guidance for the current circumstance in which beetle habitat is in the form of occasional shrubs within disconnected riparian fragments. Element IVc, which was not identified in the BA as an element with beetle habitat, has three elderberry shrubs on-site, two of which would be removed as part of the 0.29 acre of riparian impact in remaining construction. It is our best judgement to treat the sum of riparian impacts within elements IIIa, IIIb, IVa, IVc, and Va-V1a.1 (3.28 of the 4.04 acres of riparian impact) as the quantity of impacted beetle habitat for this project.

All woody plants including elderberries would be suppressed on portions of the project area through future long-term vegetation management practices (trimming, herbicide application) similar to practices without the project. According to the BA (p. 56), however, no additional area of landside or waterside woodlands beyond the impacted landside woodlands and included 9 elderberry shrubs would be removed due to future vegetation management activities associated

Table 2. Impact areas affected by RD 17 phase 3 seepage area project by cover-type divided into that conducted under emergency action in 2017 and remaining to be done; both are covered under this consultation. The shaded values are considered suitable riparian brush rabbit habitat (from RD17, see Consultation History, December 17, 2018). See text for determination of suitable beetle habitat.

Notes:

(a) Some project components were constructed during 2017 emergency response actions in Elements Ia, Ib, Ie, IIIb, IVa, Va-VIa.1, VIcde, and VIIb. Ruderal acreage impacts were duplicated between Emergency and Remaining project components for Elements Ib, Ie, VIcde, and VIIb. Developed acreage impacts were duplicated between Emergency and Remaining project components for Elements VIcde.

(b) Suitable riparian brush rabbit habitat is characterized as Great Valley cottonwood riparian and Great Valley oak riparian forest. Most of the landside riparian vegetation is sparse and lacks understory and is not suitable for this species. However, any landside riparian habitat is considered to be suitable where it is adjacent to waterside riparian habitat that is known to be occupied by or highly suitable for riparian brush rabbit (e.g., Elements IIab through VIe). North of Elements IIab, riparian habitats are limited to isolated patches of blackberry and shrubs, isolated small trees and shrubs, and isolated groves of large valley oak trees that lack understory vegetation; thus, these areas are not expected to support suitable habitat for this species. Similarly, the woodlands in the area south of the Union Pacific Railroad tracks (i.e., elements VIIe and VIIg) are characterized by nonnative and ornamental trees associated with residential development; thus, these areas are not expected to support suitable habitat for this species.

(c) Riprap would be installed on the waterside of the existing levee above the high tide line where it would intersect with the new setback levee. No riparian vegetation would be removed; only ruderal habitat would be disturbed.

[illegible]

with this project. These removed shrubs represent half of the 18 shrubs present in the surveyed project area. Nearly all of the shrubs would be removed in consecutive elements IVa, IVc, and Va-V1a.1, but the remaining shrubs are mostly just north in the vicinity of elements IIIa-b. The distribution of shrubs and any associated beetles, as well as movement of beetles, could be incrementally affected by the loss of shrubs and reduced continuity of habitat. These effects would be offset through on-site plantings (in the setback area of element IVc), and the transplantation of elderberries to a mitigation bank.

The project will include restoration of at least 9.9 acres of riparian habitat in element IVc, which is roughly three times the affected beetle habitat. Elderberry plants would be included in the form of transplants and additional plantings in to-be-determined and -approved final quantities and locations appropriate to site conditions (*see* Term and Condition #1).

Riparian Brush Rabbit

According to information provided by RD 17, there are 4.04 acres of total impact to landside riparian cover types that would be removed by project construction, of which 3.31 acres is considered rabbit habitat, consisting of roughly equal parts cottonwood forest and valley oak (Table 2). The lower value for rabbit habitat reflects the exclusion of some habitat as unsuitable for rabbit which has been or will be affected by the project to the north (elements 1a-b; fragments of natural scrub) and south (elements VIIe, g; oak trees). These excluded areas are not considered rabbit habitat due to a fragmented nature, either isolated from rather than adjacent to other rabbit habitat, or considered disturbed by nearby residential development. About 1.61 acres of the rabbit habitat loss occurred as a result of emergency action, primarily through the removal of landside oaks when seepage berm material was placed in elements IIIb and IVa. The remaining losses would be largely cottonwood forest for additional seepage berm construction in Element Va-VIa.1. All of this removed habitat is generally sparse and sometimes lacking understory vegetation that would act as cover for the rabbit. However, this habitat could be used by the rabbit because it is adjacent to waterside habitat known to be occupied or of higher suitability for occupation. Waterside habitat would not be removed by the project, nor maintained differently from current practices after the project is complete. Nevertheless, the project habitat losses have occurred or will occur in an area very close to recent rabbit record locations, so it is likely that some loss or isolation of rabbit populations will result. The project will include restoration of at least 9.9 acres of riparian scrub habitat nearby, in a setback area associated with element IVc, which is three times the area of lost habitat. This restored habitat would include a section of existing levee which would serve as refugium during high water events. This larger block of restored habitat would be available for rabbit occupation and could support more rabbits than the removed habitat, offsetting the impact of the proposed project.

About 42 acres of ruderal grassland will be affected by the project, all of which is temporary and assumed to re-establish (Table 2). Rabbits generally have a small home range and rarely venture more than a few feet from shrub cover into small openings to forage. However, this disturbance could affect rabbits by deterring their dispersal movements.

Cumulative Effects

Cumulative effects include the effects of future State, Tribal, local, or private actions that are reasonably certain to occur in the action area considered in this biological opinion. The Lower San Joaquin River Feasibility Study is another levee improvement project just north of the proposed project that encompasses 24 miles of levees in Central and North Stockton. This project will likely affect about 21 elderberry shrubs that need to be removed from levees to achieve initial compliance with Corps vegetation standands, and elderberry shrubs that re-establish would be variably affected during future maintenance. These effects would be covered and compensated under another BiOP (Service File # 08ESMF00-2015-F-0206). This project is outside the range of the rabbit.

Conclusion

After reviewing the current status of valley elderberry longhorn beetle and riparian brush rabbit, the environmental baseline for the action area, the effects of the proposed action, and the cumulative effects, it is the Service's biological opinion that the proposed project is not likely to jeopardize the continued existence of these species. This conclusion is based on:
(1) implementation of the conservation measures to minimize adverse effects on listed species during construction, (2) compensation measures which offset the effects on listed species that cannot be minimized; and (3) the expectation that the Corps granting of permission to construct the project, and its construction or subsequent certification, does not directly or indirectly affect or change current waterside maintenance practices, so that the amount and distribution of such waterside woody vegetation will not change in the future as a result of this Federal action.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harass is defined by the Service as an intentional or negligent act or omission which creates the likelihood of injury to a listed species by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding or sheltering. Harm is defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns including breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking incidental to and not intended as part of the agency action is not considered to be prohibited taking under the Act, provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by the Corps so that they become binding conditions of any grant or permit issued to the applicant, as appropriate, for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity covered by this incidental take statement. If the Corps (1) fails to assume and implement the terms and conditions or (2) fails to require an applicant to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to any permit or grant document related to the proposed project, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the Corps must report the progress of the action and its impact on the species to the Service as specified in the incidental take statement [50 CFR §402.14(i)(3)].

Amount or Extent of Take

Valley Elderberry Longhorn Beetle

The Service anticipates that incidental take of valley elderberry longhorn beetle will be difficult to detect due to its life history and ecology. Specifically, valley elderberry longhorn beetles can be difficult to locate due to the fact that a majority of their life cycle is spent in the elderberry shrub and finding a dead or injured individual is unlikely due to their relatively small size. There is a risk of harm, harassment, injury and mortality as a result of the proposed construction activities. Therefore, the Service is authorizing take incidental to the proposed action as harm, harassment, injury, and mortality of all valley elderberry longhorn beetles within 8 currently known shrubs with stems > 1 inch, and encompassing 3.28 acres of landside riparian deemed beetle habitat which will be removed due to project construction and maintained free of woody vegetation. Beetle holes or specimens are not known from the project area. We estimate the level of take in the form of harm, harass, or kill to be no more than two (2) beetles killed or injured by contact with construction equipment or motor vehicles during all project activities. The cumulative detection of two adult beetles (i.e., live or dead specimens, not exit holes) over the period of construction is to be used to determine when take is close to being exceeded. Detection of two beetles will indicate that the beetle is being affected by the project at a level where avoidance and minimization measures and project implementation need to be re-evaluated and possibly modified.

Riparian Brush Rabbit

The Service anticipates that incidental take of the rabbit will be difficult to detect or quantify for the following reasons: rabbits primarily inhabit brush from which they are difficult to observe directly, are present in low numbers, and known to be sensitive to human presence. Most close-range observations represent chance encounters that are difficult to predict, or planned trapping surveys that are not routinely done. For the proposed project, we expect incidental take to be associated with (1) harassment, through disturbance associated with project actions; (2) injury or death, due to direct contact with construction equipment or vehicles; or (3) loss of population viability due to loss or fragmentation of habitat to a point where rabbits cannot reproduce or leave an area. It is not possible to make an accurate estimate of the number of rabbits that will be harassed during construction activities, including in staging areas, roads carrying vehicular traffic, and disturbed annual grasslands, all of which could be occasionally used by the rabbit during dispersal. In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat lost or degraded as a result of the action as a surrogate measure for quantifying individuals. For the proposed project, we estimate take as all rabbits within 3.31 acres of landside woodland considered rabbit habitat. The effect of the project depends on the number of rabbits actually present and harmed. Based on these factors and our best judgment, the Service expects the level of take in the form of harm, harass, or kill to be no more than one (1) rabbit killed or injured by contact with construction equipment or motor vehicles during all project activities. Detection of one dead rabbit will indicate that the rabbit is being affected by the project at a level where avoidance and minimization measures need to be re-evaluated and possibly modified.

Effect of the Take

In the accompanying biological opinion, the Service determined that the level of anticipated take is not likely to result in jeopardy to the valley elderberry longhorn beetle and riparian brush rabbit.

Reasonable and Prudent Measure

1. The Corps shall minimize the impact of take of valley elderberry longhorn beetle and riparian brush rabbit.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must comply with, or ensure compliance with, the following terms and conditions, which implement the reasonable and prudent measure described above and outline required reporting/monitoring requirements. These Terms and Conditions are nondiscretionary.

The following Terms and Conditions implement the Reasonable and Prudent Measure:

1. The Corps must condition its Section 408 permission for the project on RD 17 providing a planting plan for the element IVc setback area and gaining Service written approval of it prior to impacts to or within 100 feet of the driplines of elderberry shrubs. The planting plan should include the numbers and approximate locations of elderberry transplants, elderberry plantings, and associated species, appropriate to site conditions and consistent with the need to compensate for impacts to both beetle and rabbit habitat. To achieve this, the planting plan is to be considered exempt from two of the numerical goals in the Service's 2017 Framework to maximize elderberry plantings (i.e., 240 stem/acre; 1 native associate:3 elderberry plantings; p. 16 *in* Service 2017). Instead, the planting plan shall include at least 50 initial elderberry plantings, which we assume will result in the long term survival of at least thirty (30) elderberry plants with stems >1 inch. Those minimum surviving 30 plants are deemed sufficient to offset impacts to the 8 affected shrubs considered beetle habitat, and up to 2 additional shrubs with stems >1 inch which may be detected in the required pre-construction survey (Reporting Requirement 2, below). The majority of the plantings shall include other riparian scrub species comparable to known riparian brush rabbit habitat. Additional elderberry plants above the 50 plantings minimum and 30 surviving may be included if this does not signficantly affect the functioning of rabbit habitat. This modified guidance is applicable for the sole use in the proposed setback area for this project and is not to be substituted by bank purchase for this

project or used as guidance in other projects. If the Corps is unable to fully comply with this condition within the proposed on-site compensation area, it must reinitiate consultation.

Reporting Requirements

In order to monitor whether the amount or extent of incidental take anticipated from implementation of the project is approached or exceeded, the Corps shall adhere to the following monitoring requirements. Should this anticipated amount or extent of incidental take be exceeded, the Corps must reinitiate formal consultation as per 50 CFR §402.16.

1. The Service must be notified within one (1) working day of the finding of any injured or dead listed species or any unanticipated damage to its habitat associated with the proposed project. Notification will be made to the Assistant Field Supervisor of the Endangered Species Program at the Bay Delta Fish and Wildlife Office at (916) 930-2664, and must include the date, time, and precise location of the individual/incident clearly indicated on a U.S. Geological Survey 7.5 minute quadrangle or other maps at a finer scale, as requested by the Service, and any other pertinent information. When an injured or dead individual of the listed species is found, the Corps (during construction) or the local sponsor (during maintenance) shall follow the steps outlined in the Disposition of Individuals Taken section below.

2. The Corps must condition its Section 408 permission for the project on RD 17 conducting a pre-construction resurvey for elderberry shrubs prior to work for each construction season in which there is an expected impact to them, of both the number of shrubs total, the number of shrubs with stem diameters > 1 inches, the size classes of those stems > 1 inch, and the presence or absence of beetle exit holes, in the work areas for that construction season. The results of the resurvey shall be used to verify or revise as necessary the quantities of removed shrubs. The survey information and any revised quantities of affected shrubs shall be transmitted to the Corps, who shall then report it to the Service at least seven (7) days prior to the onset of work; RD 17 may proceed with the work in accordance with the resurveyed quantities and compensation provided that the cumulative total shrubs affected does not exceed those in this BiOP by more than two (2) shrubs (i.e., does not exceed ten (10) shrubs). If the difference is more than two (2) shrubs, work should not be initiated and the Corps should reinitiate consultation. The Service shall seek to respond with an appropriate amendment of this BiOP within 14 calendar days to limit the impact to construction schedules.

3. The Corps will document, monitor, and report the actual amount of take of beetle and rabbit habitat for project construction in a monitoring report to be submitted within 120 days of completion of the last year of construction activities. This document will include: a summary table of the cumulative areas of disturbance of beetle and rabbit habitat by project element and the number of elderberry shrubs removed, noting any differences from that described in the BA; representative photographs before and after construction; and monitoring methods.

Disposition of Individuals Taken

Injured listed species must be cared for by a licensed veterinarian or other qualified person(s), such as the Service-approved biologist. Dead individuals must be sealed in a resealable plastic bag containing a paper with the date and time when the animal was found, the location where it was found, and the name of the person who found it, and the bag containing the specimen must be frozen in a freezer located in a secure site, until instructions are received from the Service regarding the disposition of the dead specimen. The Service contact persons are the Assistant Field Supervisor of the Endangered Species Program at the Bay Delta Fish and Wildlife Office at (916) 930-2664; and the Resident Agent-in-Charge of the Service's Office of Law Enforcement, 5622 Price Way, McClellan, California 95562, at (916) 569-8444.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. The Service recommends the following actions:

1. Develop and implement restoration measures in areas designated in the Recovery Plan for Upland Species of the San Joaquin Valley, California (Service 1998) and the Valley Elderberry Longhorn Beetle Recovery Plan (Service 1984).

REINITIATION—CLOSING STATEMENT

This concludes formal consultation on the proposed project. As provided in 50 CFR §402.16, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; (4) a new species is listed or critical habitat designated that may be affected by the action; or (5) the status of the beetle or rabbit changes. In instances where the amount or extent of incidental take is exceeded, any additional take will not be exempt from the prohibitions of section 9 of the Act, pending reinitiation.

If you have any questions regarding this biological opinion, please contact Steven Schoenberg of my staff at (916) 930-5672.

Sincerely,

Kaylee Allen
Field Supervisor
