Green Sturgeon. Green sturgeon spend more time in the marine environment than other sturgeon species (Adams *et al.* 2002 and in press). Juvenile and adult green sturgeon are likely to use the action area as habitat for adult and subadult migration and feeding, as well as growth and development to adulthood by subadults. When not spawning, this anadromous species is broadly distributed in nearshore marine areas from Mexico to the Bering Sea (NMFS 2010e). Green sturgeon use bays, estuaries, and sometimes the deep riverine mainstem in lower elevation reaches of non-natal rivers along the west coast of North America, but the distribution and timing of estuarine use is poorly understood (NMFS 2010e). Green sturgeon in the ocean will usually remain inside the 328-foot depth contour (Erickson and Hightower 2004).

Observations of green sturgeon in the Columbia River are concentrated in the estuary but have been made as far upriver as Bonneville Dam. No evidence exists for spawning in this system (Rien *et al.* 2002). Radio-tagged southern DPS green sturgeon in the Sacramento River occur seasonally in northern estuaries including the Columbia River estuary during the summer and early fall (Moser and Lindley 2006). In the Columbia River, Israel and May (2006) found the percentage of southern DPS fish to exceed 80% of total northern and southern DPS fish during late summer and early fall of some years.

The Corps and USGS have recently been working on a study of green sturgeon in the Coos and Columbia River estuaries. Although results are preliminary and sample sizes are relatively small, acoustic receivers detected green sturgeon several times off the tip of Jetty A, near the North Jetty, and in the area of Social Security beach off the Clatsop Spit (Parsley 2010). Information about specific use in the action area is still under development.

The preliminary acoustic telemetry work by the USGS on green sturgeon in the Columbia River estuary included the placing of acoustic receiver arrays approximately 300 feet from Jetty A and the North Jetty. The USGS used both acoustic and pressure-sensitive tags for this study. The receivers were capable of detecting tagged fish within 2,000 feet of the receiver, with 70 percent detection efficiency. The pressure-sensitive tags were able to detect fish at minimum depths, *e.g.*, 100 feet. Both receivers cannot determine how close the fish are to the Jetties, only that the fish were within the range of detection.

Although the USGS acoustic telemetry study does not provide information on proximity of fish relative to the Jetties, the behavioral and distribution information available on green sturgeon and their use of the Columbia River suggests that green sturgeon are likely to be in deeper areas of the MCR. Although information on habitat preferences is limited for subadult and adult green sturgeon in the Columbia River, information on white sturgeon (*Acipenser transmontanus*) in the Columbia River suggests that larger fish tend to congregate in deep pools. In a study by Parsley and Beckman (1994) they reported average water depths for juvenile white sturgeon in the Columbia River of 55 feet. This suggests, assuming habitat preferences are similar between the two species, that green sturgeon are unlikely to be found in proximity of the footprint or construction zone of the Jetties, but located more towards the navigation channel at the MCR.

Eulachon. A large percentage of the total eulachon production originates in the Columbia River basin. Spawning occurs in the mainstem of the Columbia River upstream of the estuary (Emmett *et al.* 1991, Musick *et al.* 2000) in January or February (Beacham *et al.* 2005). Additionally, eulachon usually spawn every year in the Cowlitz River, with inconsistent runs and spawning events occurring in the Gray's, Elochoman, Lewis, Kalama, and Sandy rivers (ODFW and WDFW 2009). Prior to the construction of Bonneville Dam, occasional reports were received of smelt occurring upstream as far as Hood River, Oregon, and possibly farther (Smith and Saalfeld 1955). In times of great abundance, (*e.g.*, 1945, 1953) eulachon have been known to migrate as far upstream as Bonneville Dam (Smith and Saalfeld 1955, Howell et al 2001), and are suspected of passing through the ship locks, having reached the Klickitat River (Smith and Saalfeld 1955). Though eulachon have been observed migrating up the Columbia River, spawning has not been documented in the mainstem above RM 80 (Romano *et al.* 2002).

Larval forms outmigrate through the estuary and juvenile forms rear in marine waters extending out along the continental shelf (NMFS 2008a). Eulachon larvae are approximately 0.2 inches in length and, are rapidly flushed to the ocean, often within days of hatching, and subsist on their yolk sac during this downstream dispersal (WDFW and ODFW 2001).

Information on the distribution and ecology of juvenile eulachon is scarce because they are too small to be detected in fisheries surveys, and too large to capture in ichthyoplankton surveys (Hay and McCarter 2000). It is likely that juvenile eulachon rear in near-shore marine areas at moderate or shallow depth (Barraclough 1964) and feed on pelagic plankton, including euphausiids (krill). As they grow at sea, they tend to utilize waters of greater depths and have been found as deep as 2,051 feet (Allen and Smith 1988).

Adult eulachon range in size from 5.5 to 12 inches and are planktivorous in the ocean, but stop feeding when returning to fresh water to spawn (McHugh 1939, Hart and McHugh 1944). The homing instinct of eulachon is not clearly understood, but it is postulated that larvae may spend weeks to months in nearby estuarine environments, where they grow significantly in size and may develop the capacity to imprint on large estuaries and eventually home to these areas as adults (McCarter and Hay 1999, Hay and McCarter 2000).

Eulachon return to fresh water to spawn at 2 to 5 years of age. Spawning in the lower Columbia River can occur soon after freshwater entry (ODFW and WDFW 2009). Eulachon typically enter the Columbia River in early to mid-January (although a small 'pilot' run may occur in December), followed by tributary entry in mid- to late January. Peak tributary abundance is usually in February, with variable abundance through March and an occasional showing in April (ODFW and WDFW 2009). Therefore, adult eulachon are unlikely to be present as in-water work, which is scheduled for April through October with June through October being the most likely time for in-water work due to high ocean wave and high river flow conditions in spring, and river entry have little if any overlap.

Larvae eulachon may be present in the near-and offshore oceanic environments of the action area. Although most larval eulachon should have been flushed out of the estuary to the ocean prior to the April through October in-water construction period, it is likely that not all larvae will be pelagic by April or May.

Effects on Listed Species

NMFS expects rock placement and pile installation and removal to adversely affect Steller sea lions, pile installation and removal to adversely affect humpback whales, and maintenance dredging to adversely affect eulachon.

The NMFS expects effects of construction (*i.e.*, rock transport, rock placement, construction access, staging, rock stockpiling, dredging, disposal of dredge materials, barge offloading facilities, pile installation and removal, lagoon and wetland fill, culvert replacement, dune augmentation, water quality, hydraulic and hydrological processes) on salmon, steelhead, and green sturgeon to be insignificant or discountable.

The following is a discussion of the effect of each project element on listed species and the rationales supporting our effects analysis.

Pacific Salmon and Steelhead, Green Sturgeon, and Eulachon

Rock Transport. Loaded water-borne container traffic identified as foreign in- and outbound to/from Portland that would likely have crossed the MCR in 2008 totaled approximately 195,489 ships (Corps 2010). The number of additional barge trips per year attributable to the proposed action is likely to be somewhere between 8 and 25 ships. This represents a small annual percentage increase of 0.004 to 0.01% relative to the current number of other commercial and recreational vessels already using any of these potential routes. NMFS is not aware that ship traffic in the shipping lanes of the Pacific Coast or in the MCR is currently adversely affecting salmonid, eulachon, or green sturgeon behavior. Therefore, an increase in ship traffic of 0.004 and 0.01% is unlikely to affect salmon, steelhead, eulachon, or green sturgeon behavior, fitness, migration patterns, physiology, or spatial distribution, especially since barges will be traveling at less than 12 knots. Therefore, NMFS concludes that the effects associated with rock transport on listed species are discountable.

Construction Access, Staging, Storage, and Rock Stockpiling. As described in the *Effects on Habitat* section above, effects to upland habitats will occur above mean high tide elevation. Vegetation to be removed is located in upland areas above mean high tide elevation; vegetation in these upland areas provides no habitat functions for listed species as the area is comprised of sand and European beachgrass, and BMPs will prevent disturbed sediments created by construction staging, storage, and rock stockpiling from reaching marine and estuarine waters. Therefore, NMFS concludes effects associated with construction access, staging, storage, and rock stockpiling on listed species are discountable.

Rock Placement. NMFS does not expect any listed species to be injured or killed during or as a result of placing rock for repairs and rehabilitation. This is because most of the rock will be placed on existing, relic stone that is not used by listed species (Steller sea lions being the exception). On average, 55% of all rock will be placed above MHHW, and will have no effect on listed species, except Steller sea lions. On average 24% of all rock will be placed between MLLW and MHHW. Therefore 79% of the rock will be placed in areas where few if any listed species are likely to occur, significantly reducing the probability for listed species to be injured or killed. While on average 21% of the rock will be placed below MLLW, NMFS does not expect listed species to occur in this zone as there is no biological reason (*e.g.*, food, high-energy refugia, predator avoidance) for listed species to expend energy in this high-energy, hostile environment.

Adult salmonids use deep-water water habitats when migrating through the MCR and adult and sub-adult green sturgeon migrate in deep water at the MCR, farther offshore than the spur groins and barge offloading facilities. Because rock placement will occur during June through October, eulachon larvae are unlikely to be present, and construction-related effects are expected to be discountable.

NMFS expects affects to behavior, fitness, migrating rates, or spatial distribution for adult eulachon will be insignificant as the spur groins are small (60 to 250 feet) lateral extensions of the Jetties that extend from the jetty roots to enhance stabilization of the jetty base. The MCR is more than 2 miles wide and affects on adult eulachon behavior, fitness, migration patterns, physiology, or spatial distribution are not reasonably certain to occur.

Therefore, NMFS concludes effects associated with the rock placement on listed species, are discountable.

<u>Habitat-Species Effects.</u> As described in the *Effects on Habitat* section, 9.96 acres of sandy, shallow-water inter-tidal habitat will change to rocky inter-tidal or above-tidal habitat, and 22.49 acres of rocky sub- or inter-tidal habitat will change to rocky sub-, inter-, or above- tidal habitat. The proposed habitat-type changes are not likely to result in adverse effects on behavior, fitness, migration patterns, physiology, or spatial distribution of juvenile salmon and steelhead, adult salmon and steelhead, green sturgeon, and eulachon, for the following reasons.

For salmon and steelhead, green sturgeon, and eulachon, the MCR is not used for extended periods of time, and the research on juvenile salmon and steelhead behavior at the MCR suggest that the Jetties provide no ecological function for behavioral or physiological requirements as they migrate to the ocean.

Within an estimated 3-mile proximity of the MCR jetties, approximately 19,575 acres of shallow water (-20 feet MLLW or shallower) habitat exists, of which 9.96 acres represents a conversion of 0.05 % of the shallow-water habitat. In comparison to higher peaks in distribution nearer the navigation channel, only a small percentage of juvenile salmon and steelhead, *e.g.*, approximately 5.5% use the areas between the navigation channel and the Jetties.

Based on a review of the 2005 through 2009 acoustic tag studies, the earlier studies deployed a narrower set of detection nodes. In subsequent years detection nodes were placed within ±300 feet of the North Jetty and ±800 feet of the South Jetty, with a detection range of 656 feet. Although fish may pass close to the South Jetty without being detected, the data from the multi-year study indicates that salmon and steelhead are oriented towards the navigation channel, and were consistently detected at distances greater than 656 feet from the North and South Jetties. Although a small percent occurred in the area between the Jetties and the navigation channel, an area measuring 3,200 feet wide and 6,500 feet wide, for the North Jetty and South Jetty, respectively, the data consistently indicate that salmon and steelhead in these areas outside of the navigation channel and between the Jetties are highly unlikely to occur within a few hundred feet of the Jetties. Furthermore, based on the description of the physical conditions described above under *Physical Environment at the MCR*, NMFS does not expect salmon or steelhead to occur in the construction zone as there is no biological reason, (*e.g.*, food, high-energy refugia, predator avoidance) for listed species to expend energy in this high-energy, hostile environment..

Residence time of juveniles within the larger MCR area ranges from a few hours up to, at most, a few days for the less-directed subyearling Chinook emigrants. The residence of these fish within proximity of the Jetties is therefore likely to be even shorter than the above estimates. While green sturgeon are likely to occur in the MCR as they enter and exit the Columbia River, it is likely they will be deep pools or the navigation channel rather, than near the Jetties. Eulachon are not dependent upon these rocky sub- or inter-tidal habitats in the MCR for spawning or emigration of larvae.

The anticipated area of shallow-water habitat to be altered by the proposed action intermittently is so small compared to the overall area available in the MCR, 0.05% of the area, that no significant reduction in prey available to listed species or behavioral effects are likely to result. More importantly, salmonids in the MCR feed primarily on marine insects, euphausiids (krill), zooplankton, crab megalopa, fishes, *e.g.*, Pacific herring, Groot and Margolis (1991), as opposed to benthic organisms.

Therefore, NMFS concludes effects associated with the rock placement and habitat changes on listed species will be insignificant.

Fish Predation. While piscivorous fish (*e.g.*, Pacific staghorn sculpin (*Leptocottus armatus*), and lingcod (*Ophiodon elongates*) may occupy suitable areas of new rock, these species currently occur at the Jetties and it is most likely these fish will recolonize areas where rock is being placed on existing rock habitat. Therefore, it is unknown whether piscivorous fish would increase or merely redistribute. Even if the number of piscivorous fish along the Jetties increased, it is unknown if predation rates on listed species would increase, especially since few if any listed fish are likely to be within a few hundred feet of the Jetties, based on the acoustic telemetry data, and the harsh physical environmental conditions.

As a result of jetty repairs and rehabilitation, NMFS does not expect adult or larval life stages of eulachon to be subject to potential increases in predation associated with the proposed action as: (1) There is no data available to suggest a relationship, and (2) larval eulachon are likely too small at 0.2 inches to provide any energy benefit to predators like Staghorn sculpin and lingcod.

NMFS does not expect adult and juvenile green sturgeon, adult salmon and steelhead to be affected by the proposed increase in rocky habitat for predators because they are too large to be eaten by these predators.

The proposed increase in rocky habitat and potential increase in piscivorous fish density is not reasonably likely to lead to increases in predation rates on listed fish by piscivorous fish for the following reasons:

1. The acoustic telemetry studies suggest only a small percentage of juvenile salmon and steelhead, approximately 5.5% use the areas between the Jetties and the navigation channel. This indicates that very few if any of listed salmon and steelhead will pass close enough to the Jetties to be consumed via ambush predation.
2. The MCR is a high energy, stochastic environment even during summer and fall when most of the repair and rehabilitation activities will take place, and residence time of juveniles within the larger MCR area ranges from a few hours up to at most a few days.
3. The increase in the jetty prism and expansion of the footprint below MHHW will be very small relative to the existing structure; therefore, the increase in piscivorous fish habitat and the potential increased recruitment of piscivorous fish will also be very small relative to the current number of those already along the Jetties.

Based on the above, NMFS concludes predation-associated effects on listed species are discountable.

<u>Bird Predation.</u> Key avian predators in the vicinity of the structures includes Bonaparte's gull (*Larus philadephia*), surf scoter (*Melanitta perspicillata*), common loon (*Gavia immer*), Pacific loon (*Gavia pacifica*), cormorants (*Phalacrocorax* spp.), Northwestern crow (*Corvus caurinus*), tern (*Sterna* spp.), Western grebe (*Aechmophorus occidentalis*), and bald eagle (*Haliaeetus leucocephalus*). The proposed increase in rock, particularly above MHHW, is reasonably likely to be used for perching by piscivorous birds. However, perching opportunities are already abundant along the Jetties and in the MCR. Neither avian density nor avian predation success in the MCR is likely to be limited by the quantity of rocky perches. Therefore, new perching sites are not likely to increase avian predation in a way that could be meaningfully attributed to the proposed action. Therefore, NMFS concludes predation-associated effects of the proposed action on listed species are discountable.

Mammal Predation. Marine mammals (*i.e.*, Steller sea lions, California sea lions) already use rock on the Jetties as a haul-out, mostly at the South Jetty. These animals likely prey on salmon, steelhead and sturgeon (green and white) in the MCR. It is unlikely that the quantity of haul-out space in the MCR would increase the size of marine mammal populations. The increase in haul-out area above MHHW may provide more surface area for marine mammals, but it is unlikely to increase the number of marine mammals at the MCR as this area is not a rookery. Therefore, the increase in haul-out space is unlikely to increase the magnitude, rate, or intensity of existing predation on listed species.

Dredging. The most likely adverse effect on listed species associated with dredging is entrainment. Entrainment studies of out-migrating fish carried out by Larson and Moehl (1999) at the MCR during May through October, the peak out-migration period of salmon and steelhead in the Columbia River basin, reported no entrained salmon or steelhead. The 4-year study examined 798 disposal samples. In Grays Harbor, Washington, four independent studies that monitored 798 disposal samples resulted in entrainment of 1 chum salmon over the 5-year study period (Bengston and Brown 1977, Tegelberg and Arthur 1977, Stevens 1981, and Armstrong *et al.* 1982, as cited in R2 1999).

An entrainment study carried out by R2 in 1999 examined 391 disposal samples (140 samples from the Columbia River and 251 from the Oregon Coast) and reported entrainment of two Chinook salmon at the Columbia River site. The R2 studies occurred during May through August, the peak out-migration period of salmon and steelhead in the Columbia River basin.

Buell *et al.* (1992) carried out entrainment studies on the Columbia River between RMs 102.2 and 102.5. Buell *et al.* monitored maintenance dredging of 700,000 cy between March 24 and April 10, the time of peak out-migration of salmon and steelhead in the Columbia River basin. In the Buell *et al.* study, no salmon or steelhead were entrained.

Braun (1974), as cited in Reine and Clarke (1998), reported no salmon fry entrained as a result of dredging in the Fraser River. Carlson *et al.* (2001) examined the vertical distribution of juvenile salmon in the Columbia River between RMs 32 and 43 and reported that juvenile salmon were, on average 7 to 27 feet from the bottom of the river.

Looking at the information in Larson and Moehl (1999), which examined 798 disposal samples from the MCR, approximately equal to 4 million cy of dredged material, during peak out-migration for salmon and steelhead, and the fact that they reported no entrainment of salmon or steelhead, it is unlikely that dredging of 780,000 cy spread out over a 20-year period will entrain any salmon or steelhead. Additionally, the Buell *et al.* (1992) study, which examined disposal samples for 9 days of dredging and 700,000 cy, and at depths ranging between 60 and 80 feet in the Columbia River, during the peak out-migration of salmon and steelhead, and the fact that they reported no entrainment of salmon or steelhead, it is unlikely that dredging of 780,000 cy spread out over a 20-year period will entrain any salmon or steelhead. Based on the above assessment of the literature that examined entrainment of fishes in Oregon, Washington, and British Columbia, especially the Larson and Moehl (1999) and Buell *et al.* (1992), the information on the vertical distribution of juvenile salmon in the Columbia River, the operations of dredging, *i.e.*, keeping the draghead/cutterhead below the bottom of the river, and the proposed BMPs to place the draghead/cutterhead motors in neutral if they rise 3 feet above the bottom, NMFS considers the probability of entrainment of listed species to be discountable, except for eulachon.

NMFS expects a small percentage of the approximate 1,900,000,000 to 6,500,000,000 eulachon larvae produced each year in the Columbia River basin (based on 2009 spawner biomass estimates, NMFS 2010a) to be entrained during dredging since dredging may overlap with eulachon emigration in late spring or early summer. Since eulachon larvae are dispersal migrants and may occur anywhere in the water column, NMFS considers the entrainment of larvae eulachon to be reasonably certain to occur. Entrainment will kill these eulachon larvae. Nonetheless, NMFS expects the magnitude of effect (*i.e.*, number of larvae entrained) will be small because: (1) Dredging will take place below the river bottom; (2) the dragheads or cutterheads will not be engaged if raised more than 3 feet above the river bottom; (3) the relative volume associated with dredging compared to the volume of the river flow is approximately 0.0001%; and (4) the timing of dredging will range from 3.3 to 13.3 hours per year, relative to the total outmigration period of larval eulachon of 95 to 200 days.

Dredging is likely to entrain benthic infauna. However, the magnitude and significance of effects is likely to be insignificant for listed species, as the small quantity of material dredged each year, 20,000 to 80,000 cy, represents a fraction of habitat available for benthic infauna in the MCR, *e.g.*, benthic infauna densities in the subtidal habitats in MCR ranges between 7,999 individuals to 267,283 individuals per 10.8 square feet of subtidal substrate sampled (Siipola 1994). More importantly, these areas represents a minor source of food for listed species as the primary forage items for juvenile salmon and steelhead in the MCR are marine-based, *e.g.*, marine insects, euphausiids (krill), zooplankton, crab megalopa, and fishes, Groot and Margolis (1991). Because eulachon larvae feed on plankton, their foraging habitat will not be affected by dredging. Therefore, NMFS does not expect effects associated with dredging to adversely affect behavior, fitness, migration patterns, physiology, or spatial distribution for listed species.

Increases in suspended sediment will occur during disposal. Residence time of suspended sediment in the water column is likely to be short, and increases will attenuate to background levels within minutes because the dredged material is comprised of 97% or greater sand. Dredging, especially in areas adjacent to the Jetties, will take place in areas where sediment tests have confirmed that material to be dredged is 97% or greater sand. The dredging volume will be small, between 20,000 and 80,000 cy per year, and the dredged material does not pose a risk as a source of contaminants because it consists of very little organic matter for contaminants to bind to. Based on these factors, NMFS does not expect dredging to adversely affect water quality in a manner that would meaningfully affect the behavior, fitness, migration patterns, physiology, or spatial distribution for listed species. Therefore, NMFS concludes that effects associated with dredging on listed species will be insignificant, except for eulachon.

Disposal of Dredged Materials. Disposal is likely to occur on an annual basis originating from one or more of the offloading facilities. The duration of disposal will be limited to 1 to 3 hours of disposal per year. As mentioned previously, all disposal of dredged material will be at previously evaluated and approved in-water disposal sites. NMFS has previously evaluated the effects of disposal of dredged materials at these disposal sites (NMFS 2005a), on listed fish. Using the model in NMFS 2005a to estimate the number of listed fish potentially affected by disposal, NMFS estimates that between 0.000045 to 0.00018 fish per year may be affected from disposal. Based on this estimate, NMFS concludes that effects associated with disposal of dredged materials on listed fish are discountable.

Increases in suspended sediment will occur during disposal. Residence time of suspended sediment in the water column is likely to be short, and increases will attenuate to background levels within minutes because the dredged material is comprised of 97% or greater sand. Dredging, especially in areas adjacent to the Jetties, will take place in areas where sediment tests have confirmed that material to be dredged is 97% or greater sand. The dredging volume will be small, between 20,000 and 80,000 cy per year, and the dredged material does not pose a risk as a source of contaminants because it consists of very little organic matter for contaminants to bind to. Based on these factors, NMFS does not expect dredging to adversely affect water quality in a manner that would meaningfully affect the behavior, fitness, migration patterns, physiology, or spatial distribution for listed species. Therefore, NMFS concludes that effects associated with disposal of dredged materials on listed species will be insignificant.

Barge Offloading Facilities. As described in the *Effects on Habitat* section, the installation of four barge offloading facilities and one causeway is likely to occur once, likely in the late spring or early summer prior to or during the first season of construction on the associated jetty. Effects of barge offloading facility installation and removal are discussed under the sections *Rock Placement, Pile Driving, and Dredging* as those are the components of constructing the facilities.

Pile Installation and Removal. As described in the *Effects on Habitat* section, up to 96 Z- or H-piles (12 to 16 inch diameter) could be installed as dolphins, and up to 373 sections of sheet pile installed to retain rock fill. Installation of piles is likely to happen between April and June and will be done using vibration. Piles may be removed and installed several times for a total of 1,000 pile driving or removed events. Installation and removal of piles with a vibratory hammer will introduce sound waves into the MCR area intermittently over 20 years.

Injury and death of fish from underwater noise are caused by rapid pressure changes, especially on gas-filled spaces in the bodies of fish. For this analysis, NMFS is assuming that vibratory pile driving has a similar effect on eulachon and green sturgeon as it does on salmonids, even though eulachon do not have swim bladders.

Generally, sounds from vibratory hammers are generally 10-20 dB lower than those from impact pile driving (CalTrans 2009, 4-16). While peak sound levels generated by vibratory hammers can exceed 180 dB, the sound levels rise more slowly than the sound levels generated by impact hammers (CalTrans 2009). Therefore, vibratory hammers avoid the abrupt over-and under-pressure changes exhibited by impact hammer use. General agreement does not exist on what vibratory sound exposure level (SEL) threshold value should be used for fish injury, although the likely range is 187 to 220 dB (CalTrans 2009, 4-22).

The average sound pressure levels recorded during a recent test pile program during vibratory hammering was 160 dB (peak-average); 199 dB (peak-maximum), 146 dB (SEL-average); and 181 dB (SEL-maximum) (NMFS 2010b). Therefore, given the absence of large over/under pressure changes, the understanding that injury SEL threshold values are likely in the 187 to 220 dB range, and that SEL values for vibratory hammer use are likely to be less than the discussed injury threshold, NMFS expects the proposed action would not result in the injury of fish present in the action area. Furthermore, while it is a reasonable hypothesis that SEL below 187 dB may result in behavioral responses, the data is inconclusive to determine a threshold for salmonid fishes, green sturgeon, and eulachon. Nonetheless, the data from the test pile program suggest that fishes in close proximity to the pile during installation or removal are unlikely to exhibit any behavioral responses as the reported SEL at 146 dB SEL-average is significantly below the 187 dB potential injury onset threshold. To assess potential behavioral responses in fishes, NMFS calculated the root mean square for 150 dB threshold to be at 328 feet from the source. NMFS expects few, if any, fish within a few hundred feet of the Jetties, based on the acoustic telemetry data, and therefore does not expect pile installation or removal to illicit behavioral responses in fishes.

Based on the above information, NMFS does not expect sound generated from pile installation and removal using a vibratory hammer to cause adverse effects to behavior, fitness, migration patterns, physiology, or spatial distribution of listed species, except Steller sea lions and humpback whales, which are analyzed later in this Opinion. Therefore, NMFS concludes effects associated with pile installation and removal on Pacific salmon and steelhead, green sturgeon, and eulachon will be insignificant.

Wetland and Lagoon Fill and Culvert Replacement. As described in the Effects on Habitat section, wetland (1.78 acres) and lagoon (4.71 acres) fills and culvert replacements will occur above the high tide line and will be functionally disconnected from the Columbia River as the wetland and lagoon areas are located on the landward side of North Jetty (Figure 2). The filling of the wetland and lagoon that drain into the MCR is likely to have small but insignificant effects on water quality and nutrient inputs to the Columbia River. Therefore, NMFS concludes that effects associate with wetland and lagoon fill and culvert replacement on listed species will be insignificant.

Dune Augmentation. The dune augmentation at a beach below the South Jetty will occur above mean high tide. The Corps determined that the dune augmentation actions will have immeasurable effects on listed species. Since all work will occur above

MHHW, NMFS concludes effects associated with dune augmentation on listed species will be insignificant.

Jetty Road System. As described in the *Effects on Habitat* section, the roads on top of the Jetties will be built with a mix of rock and sediment. These roads are likely to deteriorate during storm events. However, the rate of erosion and the release of road base materials through the Jetties are likely to be immeasurable as washout of the road base will occur during winter storms when waves overtop the Jetties and wave-generated suspended sediment is very high. Therefore, NMFS concludes effects associated with the jetty road system on listed species are insignificant.

Construction-Associated Leaks and Spills. As described in the *Effects on Habitat* section, the Corps will require the contractor to provide a spill prevention and management plan that will include measures to avoid and minimize the potential for leaks and spills to respond quickly to minimize damages should spills occur. Good construction practices, proper equipment maintenance, appropriate staging set-backs, and use of a Wiggins fueling system would further reduce the likelihood of leak and spill potential and exposure extent and its associated effects. NMFS has determined that spills large enough to adversely affect habitat functions cannot be reasonably expected to occur.

Therefore, NMFS concludes effects associated with the construction and contaminants on listed species are discountable.

Hydraulic and Hydrological Processes. As described in detail in the *Effects on Habitat* section, previous modeling results indicated the changes to velocities, currents, salinity, plume dynamics, and bed morphology were minimal under the much larger jetty length rebuild scenarios. Based on these previous results, no significant overall changes to the hydraulics or hydrology, and associated processes of the MCR system are likely under the new, significantly smaller proposed action. The modeling results on hydraulic and hydrological processes was run for a significantly larger project, *e.g*., restoring the South Jetty to its original length—an additional 5,000 feet in length from its present location. Those modeling results showed minor changes to velocities, currents, salinity, plume dynamics, and bed morphology, all within the range of variability. Because the current proposed action is significantly smaller, *e.g.*, no restoration of jetty lengths, the effects on velocities, currents, salinity, plume dynamics, and bed morphology are likely to be significantly less than previously determined. Although it is likely that listed species cue in on these parameters while in the MCR area, minor and intermittent changes to velocities, currents, salinity, plume dynamics, and bed morphology associated with the proposed action are within the range of natural variability and any connection to meaningful changes, positive or negative, are not possible to quantify.

Therefore, NMFS concludes that there are no hydraulic and hydrological-associated effects on listed species from repairs and rehabilitation of the Jetties.

Mitigation. The Corps estimated that a total of 38.28 acres of wetland habitats will be filled or degraded. The Corps is proposing a 2:1 mitigation ratio for wetland impacts for a total of 76.56 acres of restoration. Short-term effects associated with these activities are described above under *Habitat-Species Effects* and *Wetland and Lagoon Fill and Culvert Replacement*. In the long term, these habitat restoration actions will improve intertidal and subtidal estuarine habitats for listed species.

Steller Sea Lions

The only proposed activities NMFS anticipates will affect Steller sea lions are rock placement and pile driving, as described in detail below.

<u>Rock Placement</u>. Some Steller sea lions using haulout sites (rubble mound or concrete block) on the South Jetty are reasonably likely to be disturbed by the proposed rock placement activities. The response of Steller sea lions to the proposed rock placement may include alert behavior, approaches to the water, and flushes into the water. These potential disturbances could be caused by the movement of construction machinery and/or the noise produced by the machinery. The proposed action may also include measures to intentionally deter the Steller sea lions from using the portion of the jetty where work will occur. Such activities will be authorized under MMPA section 109(h)(1)(a), and the Steller sea lion regulations at 50 CFR 223.202(b)(2) should deterrence become necessary to protect the animals from injury during construction.

Sea lions are likely to be disturbed during the rehabilitation of the South Jetty cap and 500 feet of the jetty trunk. Steller sea lions will likely be hauling out in this area for the duration of the proposed project, *i.e*., intermittently for the next 20 years. The remaining majority of construction work will occur a significant distance from the nearest location where Steller sea lions have been observed hauling out. The number of Steller sea lions that will be incidentally or purposefully disturbed during the 20 year span of the proposed action is unknown, but all individuals that use the haulout are likely to be exposed to these activities.

The number of Steller sea lions exposed daily will vary based on weather conditions, season, and daily fluctuations of abundance at the South Jetty. Given the time of year that most of the placement will occur (spring/summer), the number of Steller sea lions affected daily could range from between 200 to 600 animals, based on past surveys (see Status of the Species). The number of Steller sea lions affected daily is likely to increase over the 20 years of project activities, because the population is currently increasing at 3% per year. It is likely that individuals will be repeatedly exposed to the rock placement activities over the 20-year period. Behaviorally, Steller sea lions may respond to rock placement by vacating the area. Some sea lions may redistribute themselves along portions of the jetty away from construction activities and to other haul out sites in the lower river and along the coast to the south and north.

Steller sea lions were flushed into the water during the repairs that were performed on the South Jetty in 2006 and 2007 (refer to NMFS No.: 2005/06359), and the effects of this proposed action are expected to be similar. During construction in 2006 and 2007, sea lions were often seen in the water close to the jetty and to a lesser extent on the jetty but appeared to be unaffected by construction activities. They often swam close to construction activities and at times appeared to feed in close proximity to construction activities. Two disturbances of pinnipeds were reported during the 2007 interim repairs. The majority of Steller sea lions occurring on the concrete block structure were far away from construction activities and undisturbed.

Based on these past responses to similar activities, NMFS finds it likely that Steller sea lion exposure to rock placement activities will change their use of the South Jetty area and the amount of time they would otherwise spend foraging in the immediate vicinity. However, there are alternative foraging areas available to the affected individuals. Repetitive, short-term displacement is likely to cause repetitive, short-term disruptions in their normal behavioral patterns at the South Jetty.

Pile Driving. As described in the proposed action and effects to the environment, approximately 24 Z- or H-piles of 12 to 16 inches in diameter could be installed as dolphins, and up to 94 sections of Z or H sheet pile (24 inch) could be installed to retain rock fill. The piles for this facility are likely to be installed as close as 600 feet from the rubble mound and 1,400 feet from the concrete block structure but as far as 6,000 feet from the concrete block structure used by Steller sea lions.

NOAA is currently developing comprehensive guidance on sound levels likely to cause injury and behavioral disruption for marine mammals in the context of the Marine Mammal Protection Act and the ESA, among other statutes. Until formal guidance is available, NMFS uses conservative exposure thresholds of sound pressure levels from broadband sounds that cause behavioral disturbance (160 dBrms re: 1µPa for impulse sound and 120 dBrms re: 1µPa for continuous sound) and injury (190 dBrms re: 1µPa for pinnipeds) (70 FR 1871). In the air, sound pressure levels greater than 100 db re:20µPa have been shown to affect behavior.

Based on these conservative thresholds, the Corps anticipates that their proposed pile driving and removal would produce sound pressure levels that are likely to disturb Steller sea lions. Underwater sound produced by the proposed vibratory pile driving and removal is anticipated to be below the injury threshold at the source. Based on conservative sound modeling, noise from vibratory installation and removal will attenuate to the 120 dB disturbance threshold within 6.2 miles (in the direction of the ocean, whereas land would be encountered on either shore of the river system prior to attenuating to the 120 dB threshold). As described for rock placement above, all individual Steller sea lions that use the South Jetty haulout are likely to be exposed to pile driving sound above the in-air and underwater disturbance thresholds of 100 dB and 120 dB, respectively, repeatedly over the 20-year period when pile driving would intermittently occur. Given the time of year that most of the pile driving would occur (spring/summer), the number of Steller sea lions affected daily could range from between 200 to 600 animals, and could increase over time because the population is growing at a rate of 3% annually (see Status of the Species).

NMFS finds it likely that Steller sea lions will be exposed to and disturbed by sound generated by pile driving activities. Steller sea lions will likely spend less time at the South Jetty haulout or foraging in the immediate vicinity. However, there are alternative foraging and haul out areas available to the affected individuals. Repetitive, short-term displacement is likely to cause repetitive, short-term disruptions in their normal behavioral patterns at the South Jetty.

Humpback Whales

The only proposed activities NMFS anticipates may adversely affect humpback whales are pile driving activities, as described in detail below.

Pile Driving. Proposed activities with potential stressors that may affect humpback whales include in-water noise from pile driving that extends out 6.2 miles into the ocean from the jetty locations. Based on the sound thresholds for marine mammals described above (see the Effects Analysis for Steller sea lions), the Corps anticipates that their proposed pile driving and removal would produce sound pressure levels that could disturb humpback whales. Sound produced by the proposed vibratory pile driving and removal is anticipated to be below the injury threshold at the source. Under-water sound produced by vibratory pile installation and removal is estimated to attenuate to the 120 dB disturbance threshold within 6.2 miles. All individual humpback whales that feed or migrate through this area up to 8.6 miles off the mouth of the Columbia River are likely to be exposed to pile driving sound above the 120 dB threshold repeatedly over the 20-year period when pile driving would intermittently occur.

As described in the Status of the Species section, we do not have fine-scale information about humpback whale use of the project area, but their occurrence in the project area is likely given their general tendency to occupy shallow, coastal waters when foraging, and the available information on their fine-scale use of a proximate location (Grays Harbor) during spring and summer months. Based on this information, humpback whales are likely to pass through and may forage in the project vicinity, within 6.2 miles of the Jetties or within approximately 8.6 miles of shore. NMFS finds it reasonable to assume that the number of humpback whales that may forage or pass through the project vicinity when pile driving would occur is best estimated by evaluating humpback whales use patterns at the most proximate location where data is available, in this case off of Grays Harbor. Given the time of year that most of the pile driving would occur (spring/summer), humpback whales may be in the project vicinity on about 50% of the days and the number of humpback whales affected could range between 0 - 19 whales per day, based on surveys off of Grays Harbor (see Status of the Species). It is likely that individuals will be exposed repeatedly to the pile driving activities over the 20 years these activities are proposed.

Exposure of humpback whales to sound at or above 120 dB threshold is likely to elicit behavioral responses within the range of previously documented responses by low-frequency hearing specialists to non-pulse sound. Southall *et al*. (2007) conducted a comprehensive literature review of the effects of sound on marine mammals and based on previous studies of low-frequency hearing specialists and their responses to non-pulse sound, they conclude that there is an increasing probability of avoidance and other behavioral effects in the 120 to 160 dB range (summarized in Table 14 from Southall *et al.* 2007). However, they caution that there is considerable variability in received levels associated with behavioral responses, and that context (*i.e*., novelty of the sound and what the animals are doing in the area) is likely as important if not more important than exposure level in predicting behavioral response.

There are no studies that document the response of low-frequency sound specialists to vibratory pile driving. Humpback whales exposed to sound from the proposed vibratory pile driving are unlikely to detect the physical presence of pile driving machinery (*i.e*., they are more likely to occur closer to the edge of the 6.2-mile radius area). For this reason, NMFS finds it reasonable to assume that of the non-pulse sound sources that have been studied, studies that have documented response to playback sound, as opposed to studies that documented response to both sound and physical presence of machinery, are most applicable to the likely response under evaluation (*i.e*., gray whales migrating: Malme *et al*. 1983, 1984, and gray whales feeding: Malme *et a*l. 1986). These studies documented responses that range from slight deviation in course and deflection around the sound (migrating whales) to avoidance of the area (feeding whales). Therefore, NMFS anticipates that humpback whales exposed to sound from the proposed pile driving in the project vicinity will respond by either a deviation in their course to deflect around the sound (in the case of whales otherwise passing through the area) or by avoiding the area (in the case of whales otherwise feeding in the area).

Exposed humpback whales are likely to be displaced and precluded from foraging in the project vicinity. However, there are alternate foraging areas available (*i.e*., areas offshore and closer to the shelf break and Grays Harbor to the north, as discussed above). Exposed humpback whales are also likely to deflect around the sound instead of passing through the area; however, the additional distance traveled is unlikely to cause a significant increase in an individual’s energy budget, and effects would therefore be non-lasting. In either case, the likely behavioral responses, even considering potential for repeat exposures of individual whales, are not anticipated to reduce the reproductive success or increase the risk of injury or mortality for any individual humpback whale.

Critical Habitat within the Action Area

The effects of the proposed action on proposed and designated critical habitat are summarized below as a subset of the habitat-related effects of the action that were discussed more fully above.

<u>Pacific Salmon and Steelhead.</u>

1. Estuarine Areas
   a. Forage – Negligible and temporary reductions in benthic invertebrates are expected at localized dredging, disposal, and rock placement sites. Effects to prey resources for listed species are

expected to be insignificant as listed species using the MCR are pelagic, not benthic feeders.

b. Free of obstruction –At the North and South jetties, multiple spur groins have been in place for decades and likely do not pose behavioral concerns, *e.g.*, affect migration patterns, for fishes, based on acoustic telemetry data. The Corps is proposing to construct 11 new spur groins that will measure between 80 and 140 feet in length. Spur groins are small lateral extensions connected to the Jetties at their base. In view of the fact that the MCR is approximately 2.5 miles wide, and that few if any salmon are likely to occur within several hundred feet of the Jetties, based acoustic telemetry data, effects associated with the new jetty spur groins on passage are likely to be discountable.

c. Natural cover – Most of the construction and staging areas will occur above MHHW. Therefore, no effects are likely to occur.

d. Water quality – Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.

e. Water quantity – No effects are likely to occur.

2. Nearshore Marine Areas

a. Free of obstruction – No effects are expected.

b. Natural cover –Most of the construction and staging areas will occur above MHHW, therefore, no effects are likely to occur.

c. Salinity – Based on the modeling, negligible effects to salinity are likely to occur.

d. Water quality – Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.

e. Water quantity – No effects are likely to occur.

3. Adult and Juvenile Migration Corridors

a. Substrate – The substrate in the MCR is mostly sand (Figure 21). Adult and juvenile salmon and steelhead will not be affected by changes in substrate composition associated with repairs and rehabilitations as this is a migratory corridor and they are not substrate-dependent for this behavior. Therefore, effects on migratory corridors will be insignificant.

b. Water quality – Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.

c. Water quantity – No effects are likely to occur.

d. Water temperature – No effects are likely to occur.

e. Water velocity – Based on modeling, small localized changes will occur in the vicinity of the spur groins. However, these are not expected to have larger scale or system-wide effects that would have a meaningful affect on habitat, especially since background velocities can exceed 8 fps in the MCR.

f. Cover/shelter – No effects are likely to occur.

g. Food Resources –Negligible and temporary impacts to benthic invertebrates are expected at localized dredging, disposal, and rock placement sites. Effects to prey resources for listed species are expected to be insignificant as effects on benthic invertebrates will be minor and listed species utilizing the MCR are pelagic feeders.

h. Riparian vegetation – Most of the construction and staging areas will occur above MHHW and will not impact natural cover for listed species. Also, vegetation in rock storage and other affected areas is mostly European bunchgrass.

i. Space – No effects to behavior, fitness, migration patterns, physiology, or spatial distribution are expected.

j. Safe passage– At the North and South jetties, multiple spur groins have been in place for decades and likely do not pose behavioral concerns, *e.g.,* affect migration patterns, for fishes, based on acoustic telemetry data. The Corps is proposing to construct 11 new spur groins that will measure between 80 and 140 feet in length. Spur groins are small lateral extensions connected to the Jetties at their base. In view of the fact that the MCR is approximately 2.5 miles wide, and that few if any salmon are likely to occur within several hundred feet of the Jetties, based acoustic telemetry data, effects associated with the new jetty spur groins on passage are likely to be discountable.

4. Areas for Growth and Development to Adulthood

a. Ocean areas – (not identified) – No effects are expected.

Based on the above assessment, the effects on the PCEs noted above will not be significant at the watershed or the designation scale of critical habitat for Pacific salmon and steelhead. Additionally, in the above analysis, the long-term beneficial effects from the proposed wetland mitigation and habitat improvement projects were not incorporated. However, the Corps is proposing to restore 76.56 acres associated with wetland impacts, and 60 acres associated with in-water impacts. These habitat restoration actions in the long term will improve intertidal and subtidal estuarine habitats for listed species. Therefore, these restoration actions are expected to beneficially affect critical habitat.

Green Sturgeon. Critical habitat was designated by the NMFS for green sturgeon. The PCEs of critical habitats relevant directly or indirectly in the action area include:

- Estuarine areas
- Coastal marine areas

1. Estuarine Areas
    a. Food Resources – Negligible and temporary reductions in benthic invertebrates are expected at localized dredging, disposal, and rock placement sites. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days only annually. This is not anticipated to have any significant or long-term effect on food abundance or distribution of green sturgeon.
    b. Migratory Corridor – The substrate in the MCR is mostly sand. Adult and juvenile green sturgeon will not be affected by changes in substrate composition associated with repairs and rehabilitations as this is a migratory corridor and they are not substrate-dependent for this behavior. Therefore, effects on migratory corridors will be insignificant.
    c. Sediment Quality – Harmful levels of contaminants have not been identified at the sites, and most of the substrate is 97% or greater sands. Therefore, no effects are likely to occur.
    d. Water Flow – No effects are likely to occur.
    e. Water Quality – Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.
    f. Water Depth – Effects will be negligible.
2. Coastal Marine Areas
    a. Food Resources – Negligible and temporary reductions in benthic invertebrates are expected at localized dredging, disposal, and rock placement sites.

b. Migratory Corridor – No effects are expected.
c. Water Quality – Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.

Based on the above assessment, the effects on the PCEs noted above will not be significant at the watershed or the designation scale of critical habitat for green sturgeon. Additionally, in the above analysis, the long-term beneficial effects from the proposed wetland mitigation and habitat improvement projects were not incorporated. However, the Corps is proposing to restore 76.56 acres associated with wetland impacts, and 60 acres associated with in-water impacts. These habitat restoration actions in the long term will improve intertidal and subtidal estuarine habitats for listed species. Therefore, these restoration actions are expected to beneficially affect critical habitat.

Eulachon.

1. Estuarine Migration Corridors
   a. Food Resources – The proposed action is not likely to have any significant or long-term effects on food resources or distribution for eulachon as juveniles eat phytoplankton, copepod eggs, copepods and other small zooplanktons and adults eat euphausiids and copepods. The project will not affect these pelagic food resources.
   b. Migratory Corridor – At the North and South jetties, multiple spur groins have been in place for decades and likely do not pose behavioral concerns for eulachon. The Corps is proposing to construct 11 new spur groins that will measure between 80 and 140 feet in length. Spur groins are small lateral extensions connected to the Jetties at their base. In view of the fact that the MCR is approximately 2.5 miles wide, effects associated with the new jetty spur groins on migration habitat are likely to be discountable.
   c. Water Flow – No effects are likely to occur.
   d. Water Quality – Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will

limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.

2. Nearshore and Offshore Marine Areas
   a. Foraging habitat—Negligible are likely to occur.
   b. Water Quality— Negligible, localized, and temporary increases in suspended sediment due to dredging, disposal, rock placement, and piling installation and removal are likely. Placement could occur during a limited time window on a seasonal daily basis, and the other actions are temporally limited to a few days annually or a single event basis. There is also potential for spills or leaks, but BMPs reduce the likelihood of this occurrence. Monitoring will limit the levels and durations of suspended sediment. Therefore, effects on water quality will be insignificant.
   c. Available Prey— The proposed action is not likely to have any significant or long-term effects on food resources or distribution for eulachon as juveniles eat phytoplankton, copepod eggs, copepods and other small zooplanktons and adults eat euphausiids and copepods. The project will not affect these pelagic food resources.

Based on the above assessment, the effects on the PCEs noted above will not be significant at the watershed or the designation scale of critical habitat for eulachon. Additionally, in the above analysis, the long-term beneficial effects from the proposed wetland mitigation and habitat improvement projects were not incorporated. However, the Corps is proposing to restore 76.56 acres associated with wetland impacts, and 60 acres associated with in-water impacts. These habitat restoration actions in the long term will improve intertidal and subtidal estuarine habitats for listed species. Therefore, these restoration actions are expected to beneficially affect critical habitat.

Cumulative Effects

Cumulative effects are those effects of future State or private activities, not involving Federal activities, that are reasonably certain to occur within the action area of the Federal action subject to consultation (50 CFR 402.02).

Some types of human activities that contribute to cumulative effects are expected to have adverse effects on listed species and critical habitat PCEs, many of which are activities that have occurred in the recent past and had an effect on the environmental baseline. These can be considered reasonably certain to occur in the future because they occurred frequently in the recent past. Within the freshwater portion of the action area, non-Federal actions are likely to include human population growth, water withdrawals (*i.e.*, those pursuant to senior state water rights) and land use practices. In marine waters within the action area, state, tribal, and local government actions are likely to be in the form of legislation, administrative rules, or policy initiatives, shoreline growth management and resource permitting. Private activities include continued resource extraction, vessel traffic, development and other activities which contribute to non-point source pollution and storm water run-off. Although these factors are ongoing to some extent and likely to continue in the future, past occurrence is not a guarantee of a continuing level of activity. That will depend on whether there are economic, administrative, and legal impediments (or in the case of contaminants, safeguards). Therefore, although NMFS finds it likely that the cumulative effects of these activities will have adverse effects commensurate to those of similar past activities; it is not possible to quantify these effects.

Synthesis and Integration of Effects

Steller Sea Lion

The Eastern DPS of Steller sea lions is a large population, which over the past 30 years has increased approximately 3% per year. Steller sea lions are generalist predators, and able to respond to changes in prey abundance. There are no substantial threats to the species, and the final recovery plan identifies the need to initiate a status review and consider removing the Eastern DPS from the Federal List of Endangered Wildlife and Plants.

The South Jetty of the Columbia River is used as a haulout all year by Steller sea lions. The only proposed activities NMFS anticipates will affect Steller sea lions are rock placement and pile driving. Given the time of year that most of the rock placement and pile driving activities will occur (spring/summer) over a 20-year timeframe, the number of Steller sea lions affected daily could range from at least 200 to 600 animals. The response of Steller sea lions to these activities are expected to be similar to repairs performed on the South Jetty in 2006 and 2007 (refer to NMFS No.: 2005/06359) and include alert behavior, approaches to the water, and flushes into the water.

NMFS finds it likely that Steller sea lions will be exposed to and disturbed by sound generated by pile driving activities. Steller sea lions will likely spend less time at the South Jetty haulout or foraging in the immediate vicinity. However, there are alternative foraging and haul out areas available to the affected individuals. Repetitive, short-term displacement is likely to cause repetitive, short-term disruptions in their normal behavioral patterns at the South Jetty. There are no current threats to the species that are either part of the environmental baseline or cumulative effects in the action area that are anticipated to affect Steller sea lion in addition to the activities of the proposed action, described above.

Humpback Whale

The current abundance of humpback whales in the North Pacific is approximately 18,000 to 21,000 whales, of which 1,400 to 1,700 individuals are part of the California/Oregon stock. Humpback whales are sighted off the Washington and Oregon coasts relatively close to shore and are known to predictably forage approximately offshore of Grays Harbor, Washington during spring and summer months.

Based on the available information about summer foraging habits of humpback whales along the Washington coast, humpback whales are likely to pass through and may forage in the project vicinity, within 6.2 miles of the Jetties or within approximately 8.6 miles of shore. The potential exposure of humpback whales to sound at or above 120 dB threshold is likely to elicit behavioral responses within the range of previously documented responses by low-frequency hearing specialists to non-pulse sound. Based on review of these documented responses, NMFS anticipates that humpback whales exposed to sound from the proposed pile driving in the project vicinity will respond by either a deviation in their course to deflect around the sound (in the case of whales otherwise passing through the area) or by avoiding the area (in the case of whales otherwise feeding in the area).

Exposed humpback whales are likely to be displaced and precluded from foraging in the project vicinity. However, there are alternate foraging areas available (*i.e*., areas offshore and closer to the shelf break and Grays Harbor to the north, as discussed above). Exposed humpback whales are also likely to deflect around the sound instead of passing through the area. In both cases, the likely behavioral responses, even considering potential for repeat exposures of individual whales, are not anticipated to reduce the reproductive success or increase the risk of injury or mortality for any individual humpback whale. In addition, current threats to the species that may occur as part of the environmental baseline or cumulative effects in this area include vessel sound that is a habitat concern for low-frequency sound specialists, such as humpback whales. Effects of the action in addition to threats that are part of the environmental baseline or cumulative effects are not anticipated to appreciably reduce the species' ability to survive and recover.

Eulachon

For eulachon, NMFS expects effects to be limited to entrainment, which will kill a small number of eulachon larvae because: (1) Dredging will take place below the river bottom; (2) the dragheads or cutterheads will not be engaged if raised more than 3 feet above the river bottom; (3) the relative volume associated with dredging compared to the volume of the river flow is approximately 0.0001%; and (4) the timing of dredging will range from 3.3 to 13.3 hours per year, relative to the total outmigration period of larval eulachon of 95 to 200 days.

Therefore, it is unlikely that the proposed action will appreciably reduce the likelihood of survival and recovery of eulachon.

Critical Habitat at the Watershed and Designation Scales

As described in the *Effects to Habitat* and *Critical Habitat with the Action Area* sections, effects to critical habitat are either insignificant or discountable. The effects will not be scalable to a reduction in conservation value because they are either intermittent, short-lived, or do not meaningfully affect the PCEs or physical or biological features of critical habitat. Therefore, NMFS concludes that the effects of the proposed action on designated critical habitat for listed species considered in the Opinion will be insignificant or discountable at the watershed and designation scales.

Conclusion

After reviewing the status of Steller sea lions, humpback whales, and eulachon, the environmental baseline, the effects of the action, and cumulative effects, NMFS concludes that the proposed action will not jeopardize the continued existence of those species

Incidental Take Statement

Section 9 of the ESA and Federal regulation pursuant to section 4(d) of the ESA prohibit the take of endangered and threatened species, respectively, without a special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harm is further defined by NMFS as significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Harass is defined by Fish and Wildlife Service as an intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not prohibited under the ESA, provided that such taking is in compliance with the terms and conditions of an incidental take statement.

Because there are no protective regulations in place for eulachon via section 4(d) of the ESA, there is no take prohibition for eulachon.

The NMFS is not including an incidental take authorization for marine mammals at this time because the incidental take of marine mammals has not been authorized under section 101(a)(5) of the Marine Mammal Protection Act and/or its 1994 Amendments. Following issuance of such regulations or authorizations, NMFS may amend this Opinion to include an incidental take statement for marine mammals, as appropriate.

Conservation Recommendations

Section 7(a) (1) of the ESA directs Federal agencies to use their authorities to further the purposes of the ESA by carrying out conservation programs for the benefit of the threatened and endangered species. The following recommendation is a discretionary measure consistent with this obligation and therefore should be carried out by the Corps:

> To improve the potential for recovery of ESA-listed species that use the MCR, the Corps should carry out management actions to reverse threats to species survival as identified in the Columbia River Estuary ESA Recovery Plan Module for Salmon and Steelhead (NMFS 2011).

Please notify NMFS if the Corps carries out this recommendation so that we will be kept informed of actions that are intended to improve the conservation of listed species or their designated critical habitats.

Reinitiation of Consultation

Reinitiation of formal consultation is required and shall be requested by the Federal agency or by NMFS where discretionary Federal involvement or control over the action has been retained or is authorized by law and: (a) If the amount or extent of taking specified in the incidental take statement is exceeded; (b) if new information reveals effects of the action that may affect listed species or designated critical habitat in a manner or to an extent not previously considered; (c) if the identified action is subsequently modified in a manner that has an effect to the listed species or designated critical habitat that was not considered in the biological opinion; or (d) if a new species is listed or critical habitat is designated that may be affected by the identified action (50 CFR 402.16).

To reinitiate consultation, contact the Oregon State Habitat Office of NMFS, and refer to the NMFS Number **2010/06104**.

NOT LIKELY TO ADVERSELY AFFECT DETERMINATIONS

Species Determinations

Blue Whales, Sei Whales, Sperm Whales, Fin Whales, Southern Resident Killer Whales, and Leatherback Sea Turtles. NMFS concurs with the Corps' "may affect, not likely to adversely affect" determinations for the following marine mammal and sea turtle species: blue whales, Sei whales, sperm whales, fin whales, Southern Resident killer whales, leatherback sea turtles. These ESA-listed species do not occur in the Columbia River, they will not be exposed to any potential stressors from the proposed activities that occur in the estuary and river proper, and no effects from activities in these areas are therefore anticipated. The above ESA-listed marine mammal and sea turtle species may occur outside of the Columbia River in the marine portion of the action area.

The proposed activity with a potential stressor in the marine portion of the action area that may affect these species is in-water noise from pile driving that extends out 6.2 miles into the ocean from the jetty locations where rock placement is proposed. Blue, fin, Sei and sperm whales and leatherback sea turtles are not generally distributed near shore. Their presence within range of in-water noise from pile driving is extremely unlikely and any effects from this activity are therefore discountable.

Southern Resident killer whales have been repeatedly observed feeding off the Columbia River plume in the vicinity of the Jetties in March and April during peak spring Chinook salmon runs (*i.e.*, in 2004: Krahn *et al*. 2004; in 2005: Zamon *et al*. 2007; in 2006: Hanson *et al*. 2008; and in 2009: Hanson *et al*. 2010). The Corps restricted the window in which piling installation will most likely be conducted (May through the summer) to avoid possible project effects that overlap with limited peak killer whale use in the project vicinity (March through April). Southern Resident killer whales can occur near shore, but their presence is likely to be infrequent and transitory, such that co-occurrence of these killer whales and proposed pile driving from May through the summer is extremely unlikely and any effects from this activity are therefore discountable.

Additionally, the proposed action is not likely to cause a measurable reduction in the quantity of salmon and other ESA-listed or proposed fish, as described above and therefore will not affect the quantity of prey available to marine mammals. The quality of prey available to marine mammals will not be adversely affected by the proposed action, because there is no causal mechanism for the proposed activities to increase the concentration of persistent organic pollutants in fish.

NMFS concurs with the Corps' determinations that effects of the action are either insignificant or discountable and therefore are not likely to adversely affect blue whales, Sei whales, sperm whales, fin whales, Southern Resident killer whales, and leatherback sea turtles.

Fishes. The NMFS concludes that the proposed action is NLAA LCR Chinook salmon, UWR Chinook salmon, UCR spring-run Chinook salmon, SR spring/summer run Chinook salmon, SR fall-run Chinook salmon, CR chum salmon, LCR coho salmon, OC coho salmon, SONCC coho salmon, SR sockeye salmon, LCR steelhead, UWR steelhead, UCR steelhead, MCR steelhead, SRB steelhead, and southern green sturgeon.

Critical Habitat Determinations

Proposed Leatherback Sea Turtle Critical Habitat. The PCEs that NMFS identified as essential for the conservation of leatherback turtles when it proposed to revise critical habit to include marine waters off the U.S. West Coast, including the action area, are: (1) A sufficient quantity and quality of their jellyfish prey; and (2) migratory pathway conditions that allow for safe and timely passage to, from, and within high use foraging areas, including areas within the action area. No effects on prey quantity or quality are anticipated. In-water noise from pile driving activities would have a discountable effect on leatherback turtle passage, given the extremely unlikely nature of leatherback turtle occurrence in the action area.

NMFS concurs with the Corps' determination that effects of the action are either insignificant or discountable and therefore are not likely to adversely affect proposed critical habitat of leatherback turtles.

Fishes. After reviewing the status of critical habitats of fish species specified above for which critical habitat is proposed or designated NMFS also concludes that the proposed action is NLAA critical habitat for those species.

MAGNUSON-STEVENS FISHERY CONSERVATION AND MANAGEMENT ACT

The consultation requirement of section 305(b) of the MSA directs Federal agencies to consult with NMFS on all actions, or proposed actions that may adversely affect EFH. Adverse effects include the direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to, benthic organisms, prey species and their habitats, and other ecosystem components, if such modifications reduce the quality or quantity of EFH. Adverse effects on EFH may result from actions occurring within EFH or outside EFH, and may include site-specific or EFH-wide impacts, including individual, cumulative, or synergistic consequences of actions (50 CFR 600.810). Section 305(b) also requires NMFS to recommend measures that may be taken by the action agency to conserve EFH.

The Pacific Fishery Management Council (PFMC) described and identified EFH for groundfish (PFMC 2005), coastal pelagic species (PFMC 1998), and Chinook salmon, coho salmon, and Puget Sound pink salmon (PFMC 1999). The proposed action and action area for this consultation are described in the Introduction to this document. The action area includes areas designated as EFH for various life-history stages groundfish species, coastal pelagic species, and Pacific salmon (Table 13).

Table 13. Species of fish and life stages with designated EFH that may occur within the action area, activities and prey.

Groundfish Species	Life stage	Activity	Prey
Arrowtooth flounder	Adults	All	Gadids, *Theragra chalcogramma*, krill, clupeids, shrimp
	Eggs	Unknown	
	Larvae		
Big skate	Adults	All	Crustaceans, fish
Black rockfish	Juveniles	Feeding, growth to maturity	
	Adults	All	
Blue rockfish	Juveniles	All	
	Adults	All	
	Larvae	Feeding	
Bocaccio	Juveniles	Feeding	Euphausiids, copepods
Butter sole	Adults	All	Polychaetes, molluscs, fish, decapod crustaceans, amphipods, shrimp, sea stars
Cabezon	Adults	All	Fish eggs, lobsters, molluscs, small fishes, crabs
California skate	Eggs	Unknown	

Groundfish Species	Life stage	Activity	Prey
Canary rockfish	Juveniles	Feeding, growth to maturity	
Chilipepper	Adults	All	Clupeids, euphausiids, *Merluccius productus*, squids, copepods, euphausiids
	Juveniles	Feeding, growth to maturity	
Copper rockfish	Adults	All	Crustaceans, fish, shrimp, molluscs
Curlfin sole	Adults	All	Crustacean eggs, *Echiurid proboscises*, nudibranchs, polychaetes
Dusky rockfish	Adults	All	
English sole	Juveniles	Feeding, growth to maturity	Polychaetes, molluscs, cumaceans, copepods, amphipods, mysids
	Adults	All	Polychaetes, ophiuroids, molluscs, cumaceans, amphipods, crustaceans
Flathead sole	Adults	All	Polychaetes, mysids, shrimp, molluscs, clupeids, fish
Kelp greenling	Adults	All	Worms, crabs, octopi, shrimp, small fishes, brittle stars, snails
	Larvae		
Lingcod	Adults	All	Juvenile crab, demersal fish, squid, octopi
	Larvae	Feeding	Decapod larvae, copepods, euphausiids, copepod nauplii, copepod eggs, amphipods
Longnose skate	Adults	All	
Pacific cod	Juveniles		Amphipods, shrimp, copepods, crabs
	Larvae		Copepods
Pacific hake	Juveniles		Euphausiids
	Adults	All	
Pacific sanddab	Adults	All	Squids, octopi, crab larvae, clupeids
Petrale sole	Adults	All	Shrimp, *Eopsetta jordani*, euphausiids, ophiuroids, pelagic fishes
Quillback rockfish	Adults	All	Amphipods, molluscs, euphausiids, polychaetes, fish juveniles, shrimp, clupeids, crabs
Redstripe rockfish	Adults	All	Fish juveniles, squid, clupeids

Groundfish Species	Life stage	Activity	Prey
Rex sole	Adults	All	Cumaceans, euphausiids, larvacea, polychaetes
Rock sole	Adults	All	Tunicates, echinoderms, fish, molluscs, polychaetes, echiurans
Rosy rockfish	Adults	All	Crabs, shrimp
Sablefish	Adults		Octopi, clupeids, euphausiids, shrimp, rockfish
	Juveniles	Growth to Maturity	Krill, small fishes, squids, euphausiids, demersal fish, tunicates, cephalopods, amphipods, copepods
	Larvae	Feeding	
Sand sole	Adults	All	Polychaetes, clupeids, crabs, fish, mysids, shrimp, molluscs
	Juveniles	Growth to Maturity, feeding	Euphausiids, molluscs, mysids, polychaetes, shrimp
Silvergray rockfish	Adults	All	
Soupfin shark	Adults	All	Fish, invertebrates
	Juveniles	Growth to Maturity	Invertebrates, fish
Spiny dogfish	Adults	All	Pelagic fishes, invertebrates
Splitnose rockfish	Juveniles	Feeding	Copepods, cladocerans, amphipods
	Larvae		
Spotted ratfish	Adults	All	Amphipods, annelids, brittle stars, fish, algae, molluscs, squids, small crustacea, ostracods, opisthobranchs, nudibranchs
	Juveniles	Growth to Maturity	Small crustacea, squids, ostracods, ophisthobranchs, nudibranchs, molluscs, fish, brittle stars, amphipods, algae, annelids
Starry flounder	Adults	Growth to Maturity	Molluscs, fish juveniles, polychaetes, crabs
	Juveniles	Feeding	Polychaetes, copepods, amphipods
Stripetail rockfish	Adults	All	Euphausiids, copepods
	Juveniles	Growth to Maturity	Copepods
Tiger rockfish	Adults	All	Juvenile rockfish, amphipods, fish juveniles, shrimp, clupeids, crabs
Vermilion rockfish	Adults		Clupeids, juvenile rockfish, krill, octopi, squids
Widow rockfish	Juveniles	Growth to Maturity, feeding	Copepods, copepod eggs, euphausiid eggs
Yellowtail rockfish	Adults	All	Clupeids, euphausiids, tunicates, mysids, salps, squid, krill, *Merluccius productus*

Groundfish Species	**Life stage**	**Activity**	**Prey**
Coastal Pelagic Species	**Life stage**	**Activity***	**Prey**
Northern anchovy	Eggs		
	Larvae		
	Juvenile		
	Adult	All	Zooplankton
Pacific sardine	Eggs		
	Larvae		
	Juvenile		
	Adult	All	Zooplankton
Pacific mackerel	Eggs		
	Larvae		
	Juvenile		
	Adult	All	Zooplankton, micronekton
Jack mackerel	Adult		Krill, small crustacea
Market squid	Eggs		
	Larvae		
	Juvenile		
	Adult	All	Plankton, small crustacea, euphausiids, copepods

Pacific Salmon			
Coho salmon**	Juvenile		
	Adults	Feeding	
Chinook salmon	Juvenile		Plankton, insects, small fish
	Adults	Feeding	
Pink Salmon	Juvenile		Plankton, insects, small fish
	Adults	Feeding	

Based on information provided by the action agency and the analysis of effects presented in the ESA portion of this document, *Effects on Habitat*, NMFS concludes that proposed action will adversely affect EFH designated for groundfish species by reducing the quality of EFH from dredging and pile installation and removal. In the long term, the increased surface area of rock for the Columbia River Jetty System will likely have beneficial habitat effects for federally-managed rockfish species.

Essential Fish Habitat Conservation Recommendations

Although NMFS did identify adverse effects associated with the proposed action on EFH, NMFS does not propose any conservation recommendations at this time as the only conservation recommendation we would recommend would be to limit the timing for dredging and pile installation and removal. Because the MCR is a high-energy environment, dredging is already limited due to weather and wave activity in the fall through spring, and dredging and pile installation and removal outside the proposed timing poses a safety hazard to dredge and pile operators.

Statutory Response Requirement

Federal agencies are required to provide a detailed written response to NMFS' EFH conservation recommendations within 30 days of receipt of these recommendations [16 U.S.C. 1855 (b)(4)(B)]. The response must include a description of measures proposed to avoid, mitigate, or offset the adverse affects of the activity on EFH. If the response is inconsistent with the EFH conservation recommendations, the response must explain the reasons for not following the recommendations. The reasons must include the scientific justification for any disagreements over the anticipated effects of the proposed action and the measures needed to avoid, minimize, mitigate, or offset such effects.

In response to increased oversight of overall EFH program effectiveness by the Office of Management and Budget, NMFS established a quarterly reporting requirement to determine how many conservation recommendations are provided as part of each EFH consultation and how many are adopted by the action agency. Therefore, we ask that in your statutory reply to the EFH portion of this consultation, you clearly identify the number of conservation recommendations accepted.

Supplemental Consultation

The Corps must reinitiate EFH consultation with NMFS if the proposed action is substantially revised in a way that may adversely affect EFH [50 CFR 600.920(k)].

DATA QUALITY ACT DOCUMENTATION AND PRE-DISSEMINATION REVIEW

Section 515 of the Treasury and General Government Appropriations Act of 2001 (Public Law 106-554) (Data Quality Act) specifies three components contributing to the quality of a document. They are utility, integrity, and objectivity. This section of the Opinion addresses these Data Quality Act (DQA) components, documents compliance with the DQA, and certifies that this Opinion has undergone pre-dissemination review.

Utility: Utility principally refers to ensuring that the information contained in this consultation is helpful, serviceable, and beneficial to the intended users.

This ESA consultation concludes that the proposed repair and rehabilitation of the Columbia River Jetty System will not jeopardize the affected listed species. Therefore, the Corps can carry out this action in accordance with its Congressional authority. The intended user is the Corps of Engineers.

Individual copies were provided to the Corps. This consultation will be posted on the NMFS Northwest Region website (http://www.nwr.noaa.gov). The format and naming adheres to conventional standards for style.

Integrity: This consultation was completed on a computer system managed by NMFS in accordance with relevant information technology security policies and standards set out in Appendix III, 'Security of Automated Information Resources,' Office of Management and Budget Circular A-130; the Computer Security Act; and the Government Information Security Reform Act.

Objectivity:

Information Product Category: Natural Resource Plan.

Standards: This consultation and supporting documents are clear, concise, complete, and unbiased; and were developed using commonly accepted scientific research methods. They adhere to published standards including the NMFS ESA Consultation Handbook, ESA Regulations, 50 CFR 402.01, *et seq.*.

Best Available Information: This consultation and supporting documents use the best available information, as referenced in the Literature Cited section. The analyses in this Opinion contain more background on information sources and quality.

Referencing: All supporting materials, information, data and analyses are properly referenced, consistent with standard scientific referencing style.

Review Process: This consultation was drafted by NMFS staff with training in ESA implementation, and reviewed in accordance with Northwest Region ESA quality control and assurance processes.

RE: SHPO Case No. 12-0338
North Jetty, Mouth of Columbia River
FOE/dredging/repair
COE
, Clatsop County

Dear Ms. Casey,

Our office recently received the cultural resources summary about the project referenced above. I have reviewed the summary document and agree that the project will have no effect on any known cultural resources. However, though the project area is largely comprised of recently accreted land forms and areas adjacent to the jetty have been dredged previously during successive repair episodes, there are known shipwrecks in the general area and it is perceived to have a high probability for submerged historic vessels.

Please be aware, that if during development activities you or your staff encounters any cultural material (i.e., historic or prehistoric), all activities should cease immediately and agency archaeologists should be contacted to evaluate the discovery. If you have any questions regarding any future discovery or my letter, feel free to contact our office at your convenience.

Sincerely,

Dennis Griffin, Ph.D., RPA
State Archaeologist

Re: MCR North Jetty Repair Project
Log No: 080709-06-COE-P

Dear Ms. Casey:

Thank you for contacting our department. We have reviewed the materials you provided for the proposed MCR North Jetty Repair Project, Cape Disappointment State Park, Pacific County, Washington.

We concur with your determination of No Historic Properties Affected.

We would appreciate receiving any correspondence or comments from concerned tribes or other parties that you receive as you consult under the requirements of 36CFR800.4(a)(4).

In the event that archaeological or historic materials are discovered during project activities, work in the immediate vicinity must stop, the area secured, and the concerned tribes and this department notified.

These comments are based on the information available at the time of this review and on the behalf of the State Historic Preservation Officer in conformance with Section 106 of the National Historic Preservation Act and its implementing regulations 36CFR800. Should additional information become available, our assessment may be revised.

Thank you for the opportunity to comment and a copy of these comments should be included in subsequent environmental documents.

Sincerely,

Robert G. Whitlam, Ph.D.
State Archaeologist

DEPARTMENT OF THE ARMY
CORPS OF ENGINEERS, PORTLAND DISTRICT
PO BOX 2946
PORTLAND OR 97208-2946

REPLY TO
ATTENTION OF

DEC 1 5 2010

Planning, Program and Project
Management Division

Dr. Kim Kratz
National Marine Fisheries Service
Oregon State Habitat Office
1201 NE Lloyd Boulevard, Suite 11 00
Portland, OR 97232

Dear Dr. Kratz:

The Portland District Corps of Engineers (Corps) has completed the Biological Assessment (BA) and Essential Fish Habitat (EFH) Assessment reports and is requesting entering into consultation for the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River (MCR). The Biological Assessment evaluates the potential impacts of the Corps' activities with regards to several federally listed marine and anadromous fish, mammal, and turtle species that are present in the proposed action area. The Corps also requests a Conference Opinion regarding effects to proposed critical habitat for leatherback turtles. Additionally, prior to construction activities, an incidental harassment authorization (IHA) for marine mammals at the South Jetty will be obtained. Based on this BA, the Corps has concluded that proposed actions will have minor adverse effects on all listed salmon species, eulachon, green sturgeon, and Stellar sea lions.

The EFH Assessment evaluates the potential impacts of the Corps' activities on five coastal pelagic species, numerous Pacific Coast groundfish species, and coho and Chinook salmon. Based on the assessment, the Corps has concluded that the proposed Jetty Major Rehabilitation will have a minor adverse effect on EFH for groundfish, pelagic fish, and salmon.

If you have any questions or need additional information, please contact Barbara Cisneros at 503-808-4784 or Barbara.G.Cisneros@usace.army.mil.

Sincerely,

Joyce E. Casey

Subject: Major Rehabilitation of the Jetty System at the Mouth of the Columbia River Navigation Channel, Clatsop County Oregon and Pacific County, Washington (USFWS Number: 13420-2011-I-0082)

Dear Ms. Casey:

This is in response to your letter received on February 8, 2011, transmitting a Biological Assessment (BA) and request for concurrence on the proposed rehabilitation of the North and South Jetties and Jetty A at the mouth of the Columbia River (MCR) navigation channel, Clatsop County Oregon and Pacific County, Washington. Of interest to the Fish and Wildlife Service (Service) is your evaluation of the impacts to listed bull trout (*Salvelinus confluentus*) and critical habitat, marbled murrelet (*Brachyramphus marmoratus*), and western snowy plover (*Charadrius alexandrinus nivosus*). The BA submitted for this proposed action includes your determination that the proposed action "may affect but is not likely to adversely affect" the above species and critical habitat. Our review and comments regarding these determinations are provided pursuant to section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1536 et seq.).

Consultation History

The Service has coordinated with the Corps on this evolving preferred alternative since 2005. Previously, the Corps submitted an earlier version of this BA proposing a larger jetty rebuild. That BA was withdrawn in January of 2008 due to significant changes in the proposed action. On February 10, 2010, the Service sent comments to the Corps based on a revised environmental assessment (CENWP-PM-E-10-03) received in our office January 14, 2010. The current proposal constitutes a new proposed action with a smaller project footprint and was determined to be the preferred alternative.

Proposed Action

The North and South Jetties and Jetty A have badly deteriorated areas where degradation has accelerated in recent years due to increased storm activity and loss of sand shoal material upon which the jetties are constructed. The purpose of this proposal is to perform modifications and repairs to the jetties at the mouth of the Columbia River that would strengthen the jetty structures, extend their functional life, and maintain deep-draft navigation. Scheduled repairs addressing the existing loss of cross sections and the addition of engineering features designed to minimize future cross section instability are planned. New groins will be constructed primarily on existing relic stone and the head capping will be placed on relic as well as jetty stone that is above MLLW. An armor stone cap of stone or equivalent concrete armor will be placed on the head the jetties. Detailed descriptions of the repair schedule, placement, and rock tonnage are provided in the BA and are incorporated here by reference.

The proposed jetty repair would be conducted by marine and/or land access activities which would include stone placement from both land and water. This includes the construction of haul roads and access ramps, placement of mooring dolphins for barges delivering stone to the jetties, and construction of equipment and rock storage areas. Placement by water could occur via the use of a jack-up barge on the South Jetty, and regular dredging and disposal of infill is expected to occur at off-loading facilities. The duration of the construction schedule is 20 years, with a 50-year operational lifetime for the MCR jetty system. Jetty rehabilitation work would occur throughout the year, where weather and other conditions allow for safe operation.

Conclusion

Based upon the information in the biological assessment, we concur with your determination that the proposed action **"may affect but is not likely to adversely affect"** bull trout and proposed critical habitat for the following reasons: 1) it is unlikely bull trout will be within the action area; and 2) the primary constituent elements of critical habitat are not likely to be degraded to an extent that is measureable or permanent.

Based upon the information in the biological assessment, we concur with your determination that the proposed action **"may affect but is not likely to adversely affect"** marbled murrelet for the following reasons: 1) conservation measures will be implemented to reduce potential noise disturbance by haul trucks through nesting habitat at Cape Disappointment State Park; 2) abundant foraging habitat is available adjacent to the activity and any disturbance would be minor and temporary; and 3) effects to prey resources would be temporary and would not impact resources known to be limiting factors to murrelet populations.

Based upon the information in the biological assessment, we concur with your determination that the proposed action **"may affect but is not likely to adversely affect"** the western snowy plover because it is unlikely to occur within the action area, and therefore exposure to effects of the proposed action is low.

Conservation Recommendations

Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, and to help implement recovery plans or to develop information. The Service recommends that the following conservation measures be implemented as a means of furthering the conservation of western snowy plovers:

1. The construction activities are proposed in the vicinity of areas known to have historical winter and breeding snowy plover populations, and are directly adjacent to the Columbia River South Jetty Snowy Plover Management Area (SPMA). During this 20-year project timeframe, the Oregon Park and Recreation Department (OPRD) will be implementing a management plan for plovers within the SPMA to restore sufficient habitat for snowy plover nesting and brood rearing to occur, reduce the amount of predators present, and keep human disturbance to a minimum. If snowy plovers attempt to nest adjacent to this activity, they could experience disturbance effects. Therefore, the Corps should survey for plover presence during the nesting season (March 15 through September 15) in areas of suitable habitat. This will help determine if snowy plovers are nesting in any given year during the life of this project. Surveys should be conducted with the Service Breeding Window Survey Protocol and coordinated with OPRD and the Service. Monitoring of plovers should be conducted a minimum of once every two weeks during the nesting season. Nesting surveys could cease after July 15, if plovers are not observed. Should plovers be observed, the Corps should immediately contact the Service and determine the next steps.

2. The Corps should consider using the heavy equipment that will already be in place at the south jetty staging area to restore and enhance nesting habitat on Clatsop Spit by removing European beach grass (*Ammophila arenaria*) or other invasive species. This area has been identified as a SPMA and is an important area for restoration of suitable habitat under the Oregon State Parks Habitat Conservation Plan for the western snowy plover.

3. The Corps should work with the OPRD to identify and prioritize specific areas for habitat creation. The Corps should consider the beneficial use of dredging material from the off-loading facilities to cover and eliminate European beach grass, especially if there is an opportunity for dune augmentation at the SPMA.

4. All garbage should be contained or removed regularly from the project site to minimize the risk of attracting additional predators, such as corvids, to the area.

If you have any questions or need more information, please Kathy Roberts of my staff at (503) 231-6179.

Sincerely,

Paul Henson, PhD
State Supervisor

COST AGENCY TECHNICAL REVIEW

CERTIFICATION STATEMENT

For

NWP – MCR Jetties
Major Rehabilitation

The MCR Jetties Major Rehabilitation project as presented by Portland District has undergone a successful Cost Agency Technical Review (Cost ATR), performed by the Walla Walla District Cost Engineering Technical Center of Expertise (Cost TCX) team. The Cost ATR included study of the project scope, report, cost estimates, schedules, escalation, and risk-based contingencies. This certification signifies the products meet the quality standards as prescribed in ER 1110-2-1150 Engineering and Design for Civil Works Projects and ER 1110-2-1302 Civil Works Cost Engineering.

As of June 13, 2012, the Cost TCX certifies the estimated total project cost of:

FY 2014 Price Level: $238,547,000
Fully Funded Amount: $257,201,000

It remains the responsibility of the District to correctly reflect these cost values within the Final Report and to implement effective project management controls and implementation procedures including risk management throughout the life of the project.

MCR JETTIES MAJOR REHABILITATION

COST ESTIMATE

Basis of Estimate

The basis for the estimate is given in scoping documents provided by the Product Development Team.

Estimate References

ER 1110-2-1302 (Civil Works Cost Engineering)
EP 1110-1-8 (Construction Equipment Ownership and Operating Expense Schedule)
ETL 1110-2-573 (Construction Cost Estimating Guide for Civil Works)

Overtime

It is anticipated that the contractor, based on required production rates and past experience, will work 6 days per week, 10 hours per shift, one shift per day.

Construction Windows

Typical weather restricts stone placement to June through September of each year. There are no in water work restrictions for placing stones.

Acquisition Strategy

The rehabilitation of the jetties will be accomplished using multi-year construction contracts, with base and optional items. For computing the Total Project Cost (TPCS) beginning in 2015, four contracts were assumed including Jetty A (2015), North Jetty (2015-2017), South Jetty (2017-2018), and South Jetty (2019-2020).

Subcontracting Plan

The estimate assumes a dredging subcontractor. All other activities to be performed by the prime contractor.

General Estimating Information

Sources of Historical Data. The 2005 MCR North Jetty repair project and the 2006 MCR South Jetty repair project were among the sources of historical data used in the preparation of this estimate.

Hazardous, Toxic and Radioactive Waste (HTRW) Remediation. No HTRW remediation will be necessary for this job.

Computation of Quantities. Quantities were computed by Coastal Engineering personnel.

Equipment/Labor Availability. Equipment of the appropriate size would likely be available from the Portland, OR area, though the large stone handling crane may need to be obtained from Seattle, WA.

Effective Dates for Labor, Equipment, Material Pricing. The effective date for all pricing is April 2012.

Equipment Rates. Equipment rates were obtained from the 2011 MII equipment region 8 database, which is derived from the equipment methodology in EP 1110-1-8.

Labor Rates. Labor rates were updated using recent Davis-Bacon rates for Clatsop County, OR and Pacific County, WA. Payroll tax and insurance rates were computed within MII. An overtime percentage was applied assuming the contractor will work six 10-hour days per week. Hourly travel costs were added for all crafts, as allowed by the latest AGC union labor agreements.

Overhead, Profit and Bond. Prime Contractor home office overhead was calculated utilizing a rule-of-thumb percentage of 10% and job office overhead was detailed out for each construction year. Profit was included as this is a budget estimate. Bond was determined using the Class B rating in MII.

A dredging subcontractor was utilized and all overhead, profit, and bond costs are included. Dredging costs are based on bid abstract information obtained from the 2006 North Coast clamshell dredging contract information for Baker Bay.

Functional Costs. Functional costs (i.e., Lands and Damages, Planning, Engineering and Design, and Construction Management) were not included as part of the construction cost but were included in the TPCS.

Total Project Costs. TPCS will show the overall project cost including contingencies, escalation, and associated administrative costs.

Contingencies. Contingencies will be developed using the Project Cost and Schedule Risk Analysis. No contingencies were added to the MII estimate.

Escalation. Escalation will be based upon the USACE Engineering Manual 1110-2-1304 Civil Works Construction Cost Index System (CWCCIS) and included in the Total Project Cost Summary (TPCS).

Specific Estimating Details

Transport of Stone to Jetty. A transportation study was completed to compare the costs of transporting stone with barges versus trucks. Typically barging is the less expensive option especially when transporting from the more distant quarries.

The methods described below for transport of the stone are those assumed in the estimate. Several stone suppliers were contacted but and provided market pricing based on assumed parameters for the project. Assumptions include a minimum density of 165 #/cf and the stone would be delivered the most economical way to the jetty and unloaded by the contractor. The actual methods used by the contractor will likely vary. Currently it is assumed stone and haul road material for jetty rehabilitation will be transported to the jetty from the quarries via a combination of highway trucks and barges. Stones will be transported in the nearest port and then barged to the project site.

Off-loading facilities will be constructed at the beginning of the initial season of jetty construction; one near the South Jetty Parking Lot D, and one near the North Jetty and Jetty A. Stones would be unloaded at the off-loading sites and transported to the staging areas near the jetty. Stone would then be re-loaded onto off-highway trucks when ready to be placed at the jetty. From the staging area, stone will be transported out to the jetties where stone is being placed by land-based equipment.

It is possible that stone may be transported from as far away as British Columbia or Northern California. If this is the case, it is likely that transportation will be by barge.

The barges would require a 20 foot draft. The barge un-loading sites would be dredged in order to meet this depth.

Jetty Stone. Quantities were given and vary depending on unit weight of the stone and the reach of the jetties the stone is to be placed. Quantities have also been increase by 10% to account for losses due to variations in stone size, shapes, and over placement outside the neat lines.

Land Based Production. Production is based on using equipment similar to what was used for the recent jetty repairs. A crane would be used to place stone that is outside the reach of the capabilities of an excavator. Assumptions for which piece of equipment to used was based on typical jetty cross-sections, stone size and distance from the equipment to where the stone is to be placed. Lifting tables and diagrams for the assumed equipment were used to determine equipment capabilities.

Assumed production rates are 100 tons/hour as an average for both the crane and excavator. The limiting factor for production is the rate the crane can place stone, while during operation with the excavator, it is the delivery rate of the stone that determines production. Historical production rates were used in determining assumed rates.

Use off-highway dump trucks to transport stone, and a dozer and front-end loader to maintain the haul road. The production rate includes time for stone placement, moving equipment, and maintenance/repairs. A separate blade and operator crew are included for maintaining the storage areas.

Weigh Scales. Scales and a scale house for weighing off-highway trucks will be needed onsite. Scales need to be 100-ton capacity. The quote obtained for the South Jetty Repairs was used. This item includes work to prepare the foundation and to set the scales. The scale house is 10 feet x 16 feet x 8 feet and of wood frame construction. It is assumed the scale house is built off-site and transported to the site. All utilities are included.

Fences and Gates. Construct a fence around the contractor's yard area, stone storage areas, and selected locations as required to direct traffic. Assume 6-foot high temporary chain link fence with a double gate with 11-foot leaves. The fence and gate will be removed at end of the individual contracts.

Jetty Haul Roads. This item consists of constructing an access road on top of the jetty, to provide a suitable smooth surface for heavy equipment. Chink rock will be used to fill in the larger holes, and then quarry run material. A 1' layer of ¾" material is included for haul road maintenance items throughout the construction period.

Haul Road Turnout. Turnouts will likely be necessary and are assumed every 500' of jetty construction beginning once the jetty extends into the ocean. The turnouts will be constructed by trucks dumping armor stone matching the *in situ* stone and rearranging stones to produce a well-keyed mass. Quarry waste will be used as haul road material on top of the jettystone. Stone in the turnouts will be used to complete the jetty rehabilitation; therefore, material costs are covered in the "Stone" items.

Quantities for each turnout: Turnout volume = 30 x 40 x 30 x 0.5/27 = 670 cy x 2.2 ton/cy = 1,474 ton less 30% voids (442 ton) = 1,031 say 1,100 ton. Turnouts are assumed to be rebuilt at the beginning of every construction season.

Design Quantities

US Army Corps
of Engineers®

Mouth of the Columbia River (MCR) Jetties
Major Rehabilitation – Preferred Plan
Project Cost and Schedule Risk Analysis Report

Prepared for:

U.S. Army Corps of Engineers,
Portland District

Prepare: February 25, 2010

U.S. Army Corps of Engineers
Cost Engineering Directory of Expertise, Walla Walla

Revised by

U.S. Army Corps of Engineers,
Portland District

Revision 120608a Updated June 8, 2012

REVISIONS

INITIAL REPORT:

Published 2/25/2010 The Cost Schedule Risk Analysis, CSRA, recommended a contingency of 29% on a total construction cost of $386 Million. Synopsis of the Project report: Base condition involved a "fix-as-fails" approach where each jetty was allowed to degrade to as low as 20 percent of the originally authorized cross section and therefore breaches were forecasted. The plan was to perform scheduled repairs with engineering features on the North Jetty and the South Jetty. Planned FOR Jetty A: immediate rehabilitation. 18 years was the estimate duration of the plans.

Revision on 4/24/2012:

Independent External Peer Review commented the previous strategy was an unrealistic assumption. The Project strategy changed. As a result, the Portland District changed the base condition to reflect the most likely future jetty maintenance strategy, one that did not allow breaches: by using interim repair with the jetty head receding. The project plan became: North Jetty Schedule Repair hold length; South Jetty base condition; Jetty A Schedule Repair hold length. CSRA was updated to match the new project scope, construction effort and risks elements. CSRA recommended contingency of 29% on a total construction cost of $160 Million. The new scope reduced the project life / duration to 7 years and reduced quantities being considered. Construction activities, materials, sources, methods and assumptions remained the same, therefore the risk elements only had minor changes. The net result for the CSRA was the same contingency percentage.

Revision on 6/8/2012

Since the Initial Report, The Corps of Engineers has continued to develop the format, documentation, and expectations for the Risk Analysis Report. This revision attempts to incorporate and address these current expectations. In additional, further review comments and project engineering and cost details have been updated and are revised in the CSRA with this current data.

EXECUTIVE SUMMARY

Under the auspices of the US Army Corps of Engineers (USACE), Portland District, this report presents a recommendation for the total project cost and schedule contingencies for the Mouth of the Columbia River (MCR) Jetties Major Rehabilitation, Preferred Plan. In compliance with Engineer Regulation (ER) 1110-2-1302 CIVIL WORKS COST ENGINEERING, dated September 15, 2008, a formal risk analysis study was conducted for the development of contingency on the total project cost. The purpose of this risk analysis study was to establish project contingencies by identifying and measuring the cost and schedule impact of project uncertainties with respect to the estimated total project cost.

The MCR Jetties Rehabilitation Project scope changed early in 2012. IEPR comments led to a revised base condition. The previous FY 11 base condition involved a "fix-as-fails" approach where each jetty was allowed to degrade to as low as 20 percent of the originally authorized cross section and therefore breaches were forecasted. An Independent Expert Panel Review IEPR comment stated that this was an unrealistic assumption. As a result, the Portland District changed the base condition to reflect the most likely future jetty maintenance strategy, one that did not allow breaches: interim repair, with the jetty head receding. The current project considers work through 2020 instead of 2032 with an estimated project cost in the range of $152 million (without contingency nor escalation) instead of $386 million previously.

Specific to the current MCR Jetties Rehabilitation Project, the most likely total project cost (at price level) is estimated at approximately $152 Million. Based on the revised results of the Cost Schedule Risk Analysis, the recommended contingency value is $47 Million, or 31%. This contingency includes $43 Million (28%) for cost growth potential due to risk analyzed in the base cost estimate and $4 Million (3%) for cost growth potential due to risk analyzed in the baseline schedule.

Portland District revised the risk analysis performed by Walla Walla Cost Dx risk analysis using the *Monte Carlo* technique, producing the aforementioned contingencies and identifying key risk drivers.

The following table ES-1 portrays the development of contingencies. The contingency is based on an 80% confidence level, as per USACE Civil Works guidance.

Table ES-1. Contingency Analysis Table

Most Likely Cost Estimate	$152,519,000	
Confidence Level	**Value ($$)**	**Contingency (%)**
5%	$172,842,000	13%
50%	$190,033,000	25%
80%	**$199,411,000**	**31%**
95%	$208,549,000	37%

The following table ES-2 portrays the full costs of the recommended alternative based on the anticipated contracts. The costs are intended to address the congressional request of estimates to implement the project. The contingency is based on an 80% confidence level, as per accepted USACE Civil Works guidance.

Table ES-2. Cost Summary

MCR Jetties Major Rehabilitation		COST ($1,000)	CNTG ($1,000)	TOTAL ($1,000)
10	BREAKWATER AND SEAWALLS	167,759	51,838	219,597
30	PLANNING, ENGINEERING AND DESIGN	18,790	5,806	24,596
31	CONSTRUCTION MANAGEMENT	9,938	3,071	13,009
	TOTAL PROJECT COSTS	**196,487**	**60,714**	**257,201**
	Schedule Completion with Contingency	**31 Oct 2020**	**40 months**	**29 Feb 2024**

Notes:
1) Recommended contingency of 31%.
2) Costs exclude O&M and Life Cycle Cost estimates.

KEY FINDINGS/OBSERVATIONS RECOMMENDATIONS

The key cost risk drivers identified through sensitivity analysis were the following Risk Elements. These 6 Risk Elements together contributed to 78% of the statistical cost variance.

COST VARIANCE

- Risk CA-1 Incomplete Acquisition Strategy: The details of the acquisition plan in terms of the technique to let the contracts has not been fully developed. This contributed 21% of the statistical cost variance.

- Risk CON-1 Stone Quarry Site/Material Availability and Delivery: The availability and supply of stone and cranes could be an issue, depending on when the construction occurs and how much is being demanded concurrently. The sheer volume required for this project could overwhelm the local market for supply of stone of this size and quantity. This contributed 17% of the statistical cost variance.

- Risk STL-VEQ (South Jetty) Variation in Estimated Quantities: Due to the fact that the project is at a feasibility level, the quantities of stone estimated could change positively or negatively. This contributed 14% of the statistical cost variance.

- Risk PR-5 Unexpected Escalation on Stone: There could be an unusual demand on stone, causing an unexpected spike in pricing. This contributed 11% of the statistical cost variance.

- Risk PR-7 Market Conditions and Bidding Climate: There is inherent risk of cost fluctuations created by the contractors available to perform this work, as well as the effects on the market by escalation, especially due to the length of the project. This contributed 9% of the statistical cost variance.

- Risk CA-2 Numerous Separate Contracts: There are 4 separate construction contracts planned. Numerous contracts for the project may increase the costs of contracting, and lead to less favorable contract markups, and lack of efficiencies, increasing the construction costs. This contributed 6% of the statistical cost variance.

SCHEDULE VARIANCE

The key schedule risk drivers identified through sensitivity analysis were the following Risk Elements. These 4 Risk Elements together contributed to 74% of the statistical schedule variance.

- Risk TL-1 Variation in Estimated Quantities: The Project is at a feasibility level, the quantities of stone estimated could change positively or negatively. Fluctuations in quantities may delay project completion. This contributed 46% of the statistical schedule variance.

- Risk RE-5 Agency Actions Take Longer than Expected: NMFS has completed their BIOP for the project, but it requires a separate consultation for 71 habitat improvements. This contributed 11% of the statistical schedule variance.

- Risk PR-2 Adequacy of Project Funding: The current working estimate and schedule assumes obtaining outlays in an anticipated schedule and funding profile. If the timing and outlay amounts differ from the plan, it could alter the scope and scheme of implementation thereby delaying the project completion. This contributed 10% of the statistical schedule variance.

- Risk PPM-8 Unplanned Work that Must Be Accommodated: If reviews or results of models require work to be performed that has not been planned, it could impact schedule. This contributed 8% of the statistical schedule variance.

Recommendations, as detailed within the main report, include the implementation of cost and schedule contingencies, further iterative study of risks throughout the project life-cycle, potential mitigation throughout the PED phase, and proactive monitoring and control of risk identified in this study.

MAIN REPORT

1.0 PURPOSE

Under the auspices of the US Army Corps of Engineers (USACE), Portland District, this report presents a recommendation for the total project cost and schedule contingencies for the Mouth of the Columbia River (MCR) Jetties Major Rehabilitation Preferred Plan.

2.0 BACKGROUND

The Mouth of the Columbia River (MCR) Jetties Major Rehabilitation (MCR Jetties Rehab) project consists of three major components: 1) North Jetty, 2) South Jetty, and 3) Jetty A. The project is currently in the feasibility stage, although the project was previously authorized. The current working estimate value without contingency is approximately $152 Million. The project is anticipated to be 7 years in duration, with the rehabilitation occurring in several phases. The priority is for schedule repair to the jetties to reduce the chance of breach. The repairs do not include the jetty heads nor spur groins. Weather conditions typically restrict work to between June and September. No HTRW or cultural resource issues are anticipated for the work.

As a part of this effort, Portland District requested that the USACE Cost Engineering Directory of Expertise for Civil Works (Cost Engineering Dx) provide an agency technical review (ATR) of the cost estimate and schedule for Recommended Project Plan. That tasking also included providing a risk analysis study to establish the resulting contingencies. The work was updated to the current information with Revision 120608a.

3.0 REPORT SCOPE

The scope of the risk analysis report is to calculate and present the cost and schedule contingencies at the 80 percent confidence level using the risk analysis processes, as mandated by U.S. Army Corps of Engineers (USACE) Engineer Regulation (ER) 1110-2-1150, Engineering and Design for Civil Works, ER 1110-2-1302, Civil Works Cost Engineering, and Engineer Technical Letter 1110-2-573, Construction Cost Estimating Guide for Civil Works. The report presents the contingency results for cost risks for all project features. The study and presentation does not include consideration for life cycle costs.

3.1 Project Scope

The formal process included extensive involvement of the PDT for risk identification and the development of the risk register. The analysis process evaluated the most likely Micro Computer Aided Cost Estimating System (MCACES) cost estimate, schedule, and funding profiles using Crystal Ball software to conduct a *Monte Carlo* simulation and statistical sensitivity analysis, per the guidance in Engineer Technical Letter (ETL) CONSTRUCTION COST ESTIMATING GUIDE FOR CIVIL WORKS, dated September 30, 2008.

The project technical scope, estimates and schedules were developed and presented by the Portland District. Consequently, these documents serve as the basis for the risk analysis.

The scope of this study addresses the identification of problems, needs, opportunities and potential solutions that are viable from an economic, environmental, and engineering viewpoint.

3.2 USACE Risk Analysis Process

The risk analysis process for this study follows the USACE Headquarters requirements as well as the guidance provided by the Cost Engineering Dx. The risk analysis process reflected within this report uses probabilistic cost and schedule risk analysis methods within the framework of the Crystal Ball software. Furthermore, the scope of the report includes the identification and communication of important steps, logic, key assumptions, limitations, and decisions to help ensure that risk analysis results can be appropriately interpreted.

Risk analysis results are also intended to provide project leadership with contingency information for scheduling, budgeting, and project control purposes, as well as to provide tools to support decision making and risk management as the project progresses through planning and implementation. To fully recognize its benefits, cost and schedule risk analysis should be considered as an ongoing process conducted concurrent to, and iteratively with, other important project processes such as scope and execution plan development, resource planning, procurement planning, cost estimating, budgeting and scheduling.

In addition to broadly defined risk analysis standards and recommended practices, this risk analysis was performed to meet the requirements and recommendations of the following documents and sources:

- Cost and Schedule Risk Analysis Process guidance prepared by the USACE Cost Engineering Dx.

- Engineer Regulation (ER) 1110-2-1302 CIVIL WORKS COST ENGINEERING, dated September 15, 2008.

- Engineer Technical Letter (ETL) CONSTRUCTION COST ESTIMATING GUIDE FOR CIVIL WORKS, dated September 30, 2008.

4.0 METHODOLOGY / PROCESS

The Portland cost engineer facilitated a risk identification and qualitative analysis meeting the Portland PDT on February 17, 2010. The initial risk identification meeting also included qualitative analysis to produce a risk register that served as the framework for the risk analysis. The Portland cost engineer assisted in the creation of the cost and schedule risk analysis models, and obtained the assistance of the Walla Walla Cost Dx to complete the analysis and the report.

The initial cost and schedule risk models were completed and results reported on March 27, 2010. As a result of changes to the technical scope, planning documents, and estimate updates, as well as changes recommended through the Agency Technical Review (ATR) process, revisions and iterations of the cost and schedule risk model took place between March 27, 2010 and November 15, 2010. The results were completed and reported on February 25, 2011.

After February 2011, until April 2012, IEPR comments led to a revised base condition. The current project considers work through 2020 instead of 2032 with an estimated project cost in the range of $152 million (without contingency nor escalation) instead of $386 million previously. The Cost Schedule Risk Analysis was revised to include the current plan, data, and information. to match the current project. This revision is noted as "Revision 120608a".

The risk analysis process for this study is intended to determine the probability of various cost outcomes and quantify the required contingency needed in the cost estimate to achieve any desired level of cost confidence.

Contingency is an amount added to an estimate to allow for items, conditions or events for which the occurrence or impact is uncertain and that experience suggests will likely result in additional costs being incurred or additional time being required. The amount of contingency included in project control plans depends, at least in part, on the project leadership's willingness to accept risk of project overruns. The less risk that project leadership is willing to accept the more contingency should be applied in the project control plans. The risk of overrun is expressed, in a probabilistic context, using confidence levels.

The Cost Dx guidance for cost and schedule risk analysis generally focuses on the 80-percent level of confidence (P80) for cost contingency calculation. It should be noted that use of P80 as a decision criteria is a risk averse approach (whereas the use of P50 would be a risk neutral approach, and use of levels less than 50 percent would be risk seeking). Thus, a P80 confidence level results in greater contingency as compared to a P50 confidence level. The selection of contingency at a particular confidence level is ultimately the decision and responsibility of the project's District and/or Division management.

The risk analysis process uses *Monte Carlo* techniques to determine probabilities and contingency. The *Monte Carlo* techniques are facilitated computationally by a commercially available risk analysis software package (Crystal Ball) that is an add-in to Microsoft Excel. The level of detail recreated in the schedule is sufficient for risk analysis purposes that reflect the established risk register.

The primary steps, in functional terms, of the risk analysis process are described in the following subsections. Risk analysis results are provided in Section 6.

4.1 Identify and Assess Risk Factors

Identifying the risk factors via the PDT is considered a qualitative process that results in establishing a risk register that serves as the document for the quantitative study using the Crystal Ball risk software. Risk factors are events and conditions that may influence or drive uncertainty in project performance. They may be inherent characteristics or conditions of the project or external influences, events, or conditions such as weather or economic conditions. Risk factors may have either favorable or unfavorable impacts on project cost and schedule.

Checklists or historical databases of common risk factors are sometimes used to facilitate risk factor identification. However, key risk factors are often unique to a project and not readily derivable from historical information. Therefore, input from the entire PDT was obtained using creative processes such as brainstorming or other facilitated risk assessment meetings.

Formal PDT meetings were held for the purposes of identifying and assessing risk factors. The formal meeting conducted on February 17, 2010 included personnel with the following Titles and related functions:

No.	Section	Title
1	CENWP-PM-F	Project Manager
2	CENWP-PM-F	Chief, Project Management
3	CENWP-EC-CC	Cost Engineer
4	CENWP-EC-HY	Hydraulic Engineer
5	CENWP-EC-HY	Chief, Hydraulic Design
6	CENWD-RBT	Division Construction Chief
7	CENWP-EC-CC	Senior Cost Engineering
8	CENWP-EC-CC	Supervisory Geologist, Chief Cost Engineering & Construction Services
9	CENWW-EC-X	Cost Engineer/Risk Facilitator

The initial formal meetings focused primarily on risk factor identification using brainstorming techniques, but also included some facilitated discussions based on risk factors common to projects of similar scope and geographic location. Subsequent meetings focused primarily on risk factor assessment and quantification.

Agency Technical Review (ATR) of the cost estimate and schedule products also identified additional risks for consideration. These risks were: CON-6 (Consideration for Post-Award Contract Modifications), which represents the inherent risk of contract modifications during construction due to differing site conditions and engineering changes, and EST-5 (Productivity of Contractor Labor and Equipment), which represents the risk that contractors may be more or less efficient than currently reflected in the baseline estimate and schedule. These risks were added based on historical experience with projects of this nature.

4.2 Quantify Risk Factor Impacts

The quantitative impacts of risk factors on project plans were analyzed using a combination of professional judgment, empirical data and analytical techniques. Risk factor impacts were quantified using probability distributions (density functions) because risk factors are entered into the Crystal Ball software in the form of probability density functions.

Similar to the identification and assessment process, risk factor quantification involved multiple project team disciplines and functions. However, the quantification process relied more extensively on collaboration between cost engineering and risk analysis team members with lesser inputs from other functions and disciplines. This process used an iterative approach to estimate the following elements of each risk factor:

- Maximum possible value for the risk factor
- Minimum possible value for the risk factor
- Most likely value (the statistical mode), if applicable
- Nature of the probability density function used to approximate risk factor uncertainty
- Mathematical correlations between risk factors
- Affected cost estimate and schedule elements

The resulting product from the PDT discussions is captured within a risk register as presented in Section 6 for both cost and schedule risk concerns. Note that the risk register records the PDT's risk concerns, discussions related to those concerns, and potential impacts to the current cost and schedule estimates. The concerns and discussions support the team's decisions related to event likelihood, impact, and the resulting risk levels for each risk event.

4.3 Analyze Cost Estimate and Schedule Contingency

Contingency is analyzed using the Crystal Ball software, an add-in to the Microsoft Excel format of the cost estimate and schedule. *Monte Carlo* simulations are performed by applying the risk factors (quantified as probability density functions) to the appropriate estimated cost and schedule elements identified by the PDT. Contingencies are calculated by applying only the moderate and high level risks identified for each option (i.e., low-level risks are typically not considered, but remain within the risk register to serve historical purposes as well as support follow-on risk studies as the project and risks evolve).

For the cost estimate, the contingency is calculated as the difference between the P80 cost forecast and the baseline cost estimate. Each option-specific contingency is then allocated on a civil works feature level based on the dollar-weighted relative risk of each feature as quantified by *Monte Carlo* simulation. Standard deviation is used as the feature-specific measure of risk for contingency allocation purposes. This approach results in a relatively larger portion of all the project feature cost contingency being allocated to features with relatively higher estimated cost uncertainty.

5.0 PROJECT ASSUMPTIONS

The following data sources and assumptions were used in quantifying the costs associated with the with- and without-project conditions.

a. The MII MCACES (Micro-Computer Aided Cost Estimating Software) file "MCR Preferred Plan 120608.mlp" was the basis for the cost and schedule risk analyses revision 120608a.

b. The cost comparisons and risk analyses performed and reflected within this report are based on design scope and estimates that are at the feasibility level.

c. The schedule was analyzed for impact to the project cost in terms of both uncaptured escalation (variance from OMB factors and the local market) and monthly recurring costs (unavoidable fixed contract costs and/or languishing federal administration costs incurred throughout delay).

d. Per the CWCCIS Historical State Adjustment Factors in EM 1110-2-1304, State Adjustment Factor for Oregon is 1.07, meaning that historical inflation is up to 7% higher than the national average.

e. Per the data in the estimate, the Job Office Overhead (JOOH) amount for the Contract Cost comprises approximately 5.7% of the Project Cost at Baseline. Thus, the assumed monthly recurring rate for this project is 5.7%. For the P80 schedule, this comprises approximately 3% of the total contingency due to the accrual of residual fixed costs associated with delay.

f. The Cost Dx guidance generally focuses on the eighty-percent level of confidence (P80) for cost contingency calculation. For this risk analysis, the eighty-percent level of confidence (P80) was used. It should be noted that the use of P80 as a decision criteria is a moderately risk averse approach, generally resulting in higher cost contingencies. However, the P80 level of confidence also assumes a small degree of risk that the recommended contingencies may be inadequate to capture actual project costs.

g. Only high and moderate risk level impacts, as identified in the risk register, were considered for the purposes of calculating cost contingency. Low level risk impacts should be maintained in project management documentation, and reviewed at each project milestone to determine if they should be placed on the risk "watch list" for further monitoring and evaluation.

6.0 RESULTS

The cost and schedule risk analysis results are provided in the following sections. In addition to contingency calculation results, sensitivity analyses are presented to provide decision makers with an understanding of variability and the key contributors to the cause of this variability.

6.1 Risk Register

A risk register is a tool commonly used in project planning and risk analysis. The actual risk register is provided in CSRA Attachment A. The complete risk register includes low level risks, as well as additional information regarding the nature and impacts of each risk.

It is important to note that a risk register can be an effective tool for managing identified risks throughout the project life cycle. As such, it is generally recommended that risk registers be updated as the designs, cost estimates, and schedule are further refined, especially on large projects with extended schedules. Recommended uses of the risk register going forward include:

- Documenting risk mitigation strategies being pursued in response to the identified risks and their assessment in terms of probability and impact.
- Providing project sponsors, stakeholders, and leadership/management with a documented framework from which risk status can be reported in the context of project controls.
- Communicating risk management issues.
- Providing a mechanism for eliciting feedback and project control input.
- Identifying risk transfer, elimination, or mitigation actions required for implementation of risk management plans.

6.2 Cost Contingency and Sensitivity Analysis

Table 1 provides the raw construction cost contingencies calculated for the P80 confidence level and rounded to the nearest thousand. The construction cost contingencies for the P50 and P100 confidence levels are also provided for illustrative purposes only.

Contingency was quantified as approximately $47 Million at the P80 confidence level (31% of the baseline cost estimate). For comparison, the cost contingency at the P50 and P100 confidence levels was quantified as 25% and 49% of the baseline cost estimate, respectively.

Table 1. Project Cost Contingency Summary

Risk Analysis Forecast	Baseline Estimate	Project Contingency[1,2] ($)	Total Contingency (%)
50% Confidence Level			
Project Cost	$190,033,000	$37,514,000	25%
80% Confidence Level			
Project Cost	$199,411,000	$46,892,000	31%
100% Confidence Level			
Project Cost	$231,528,000	$79,009,000	52%

Notes:
1) These figures combine uncertainty in the baseline cost estimates and schedule.
2) A P100 confidence level is an abstract concept for illustration only, as the nature of risk and uncertainty (specifically the presence of “unknown unknowns”) makes 100% confidence a theoretical impossibility.

6.2.1 Sensitivity Analysis

Sensitivity analysis generally ranks the relative impact of each risk/opportunity as a percentage of total cost uncertainty. The Crystal Ball software uses a statistical measure (contribution to variance) that approximates the impact of each risk/opportunity contributing to variability of cost outcomes during *Monte Carlo* simulation.

Key cost drivers identified in the sensitivity analysis can be used to support development of a risk management plan that will facilitate control of risk factors and their potential impacts throughout the project lifecycle. Together with the risk register, sensitivity analysis results can also be used to support development of strategies to eliminate, mitigate, accept or transfer key risks.

6.2.2 Sensitivity Analysis Results

The risks/opportunities considered as key or primary cost drivers are ranked in order of importance in contribution to variance bar charts. Opportunities that have a potential to reduce project cost and are shown with a negative sign; risks are shown with a positive sign to reflect the potential to increase project cost. A longer bar in the sensitivity analysis chart represents a greater potential impact to total project cost.

Figure 1 presents a sensitivity analysis for cost growth risk from the high level cost risks identified in the risk register. Likewise, Figure 2 presents a sensitivity analysis for schedule growth risk from the high level schedule risks identified in the risk register.

6.3 Schedule and Contingency Risk Analysis

Table 2 provides the schedule duration contingencies calculated for the P80 confidence level. The schedule duration contingencies for the P50 and P100 confidence levels are also provided for illustrative purposes.

Schedule duration contingency was quantified as 40 months based on the P80 level of confidence. These contingencies were used to calculate the projected monthly recurring cost impact of project delays that are included in the Table 1 presentation of total cost contingency. The schedule contingencies were calculated by applying the high level schedule risks identified in the risk register for each option to the durations of critical path and near critical path tasks.

The schedule was not resource loaded and contained open-ended tasks and non-zero lags (gaps in the logic between tasks) that limit the overall utility of the schedule risk analysis. These issues should be considered as limitations in the utility of the schedule contingency data presented. Schedule contingency impacts presented in this analysis are based solely on projected monthly recurring costs.

Table 2. Schedule Duration Contingency Summary

Risk Analysis Forecast	Schedule Duration (months)	Contingency[1] (months)	Contingency (%)
50% Confidence Level			
Total Project Duration	131	31.2	31%
80% Confidence Level			
Total Project Duration	139	40.0	40%
100% Confidence Level			
Total Project Duration	165	66.0	66%

Notes:
1) The schedule was not resource loaded and contained open-ended tasks and non-zero lags (gaps in the logic between tasks) that limit the overall utility of the schedule risk analysis. These issues should be considered as limitations in the utility of the schedule contingency data presented in Table 2.
2) A P100 confidence level is an abstract concept for illustration only, as the nature of risk and uncertainty (specifically the presence of "unknown unknowns") makes 100% confidence a theoretical impossibility.

Figure 1. Cost Sensitivity Analysis

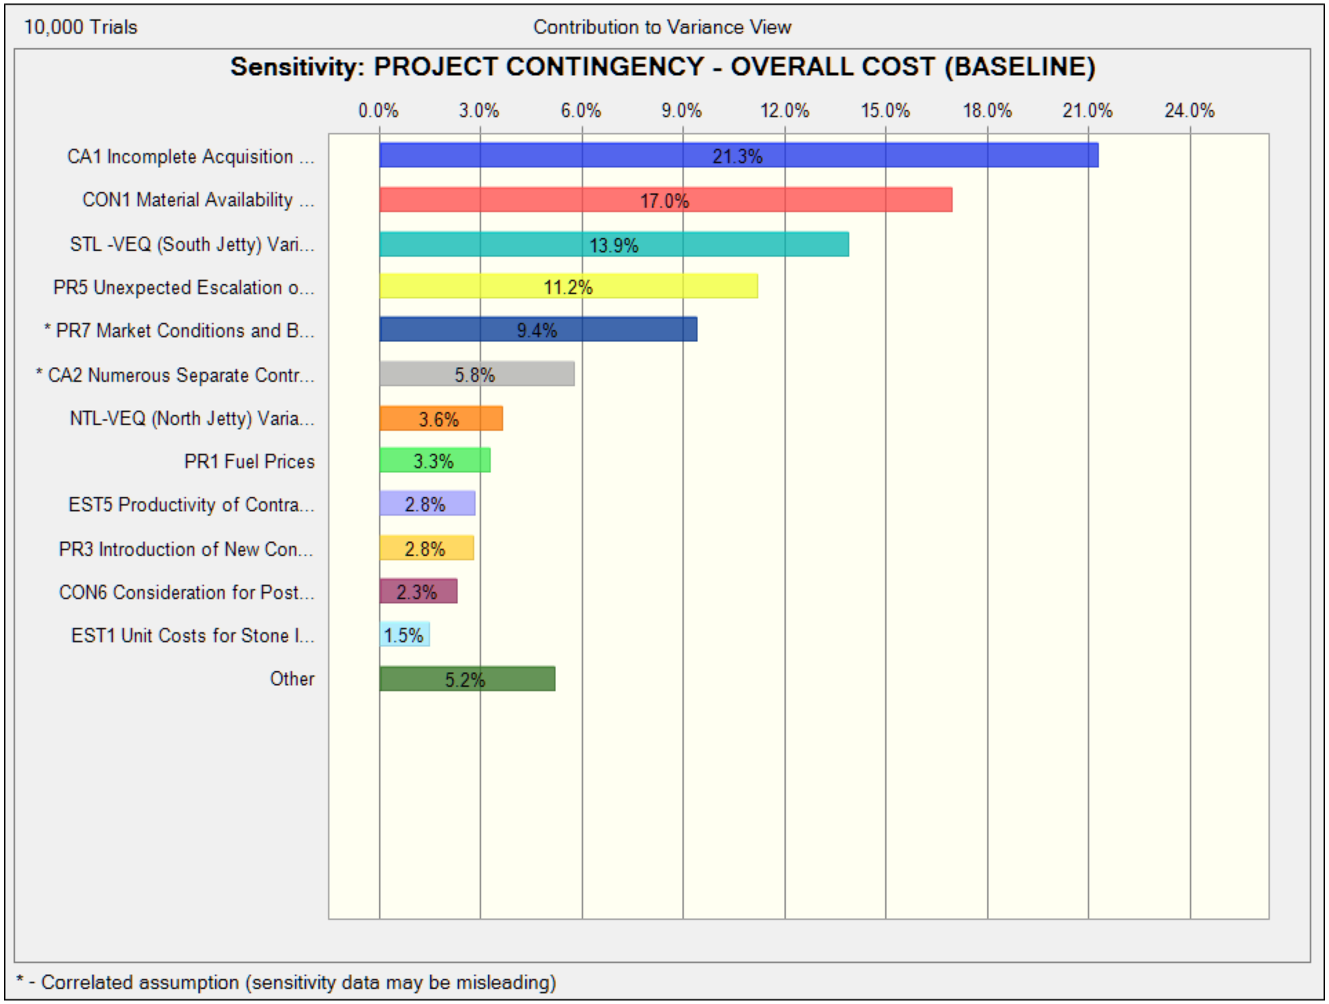

Figure 2. Schedule Sensitivity Analysis

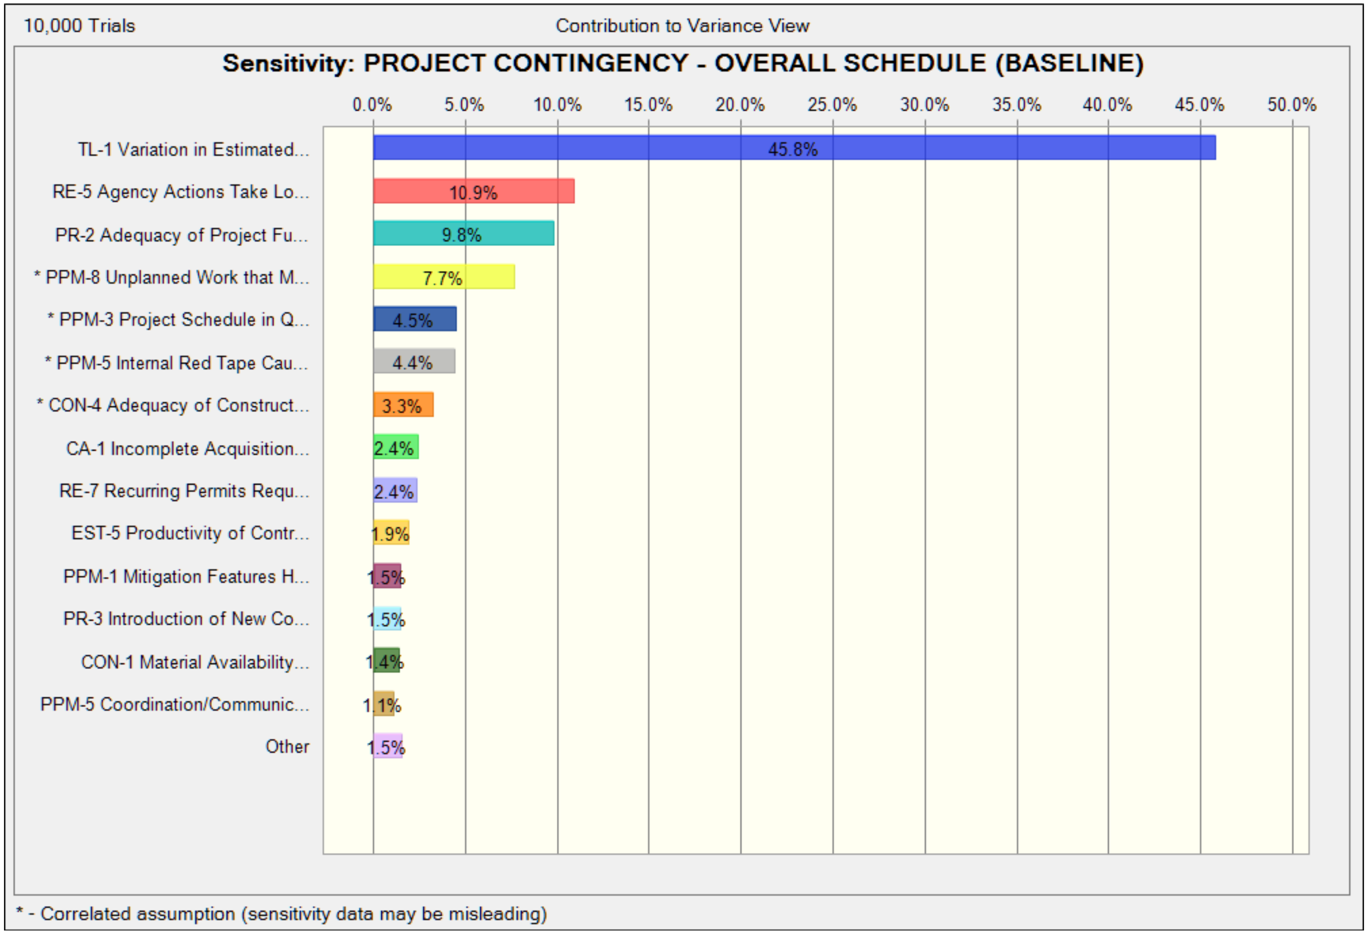

7.0 MAJOR FINDINGS/OBSERVATIONS/RECOMMENDATIONS

This section provides a summary of significant risk analysis results that are identified in the preceding sections of the report. Risk analysis results are intended to provide project leadership with contingency information for scheduling, budgeting, and project control purposes, as well as to provide tools to support decision making and risk management as projects progress through planning and implementation. Because of the potential for use of risk analysis results for such diverse purposes, this section also reiterates and highlights important steps, logic, key assumptions, limitations, and decisions to help ensure that the risk analysis results are appropriately interpreted.

7.1 Major Findings/Observations

Total project cost comparison summaries are provided in Table 3 and Figure 3. Additional major findings and observations of the risk analysis are listed below.

1. The key cost risk drivers identified through sensitivity analysis were Risks CA-1 Incomplete Acquisition Strategy, CON-1 Stone Quarry Site/Material Availability and Delivery, STL-VEQ (South Jetty) Variation in Estimated Quantities, PR-5 Unexpected Escalation on Stone, PR-7 Market Conditions and Bidding Climate, CA-2 Numerous Separate Contracts These 6 risk elements together contribute over 78 percent of the statistical cost variance.

2. The key schedule risk drivers identified through sensitivity analysis were Risks TL-1 Variation in Estimated Quantities, RE-5 Agency Actions Take Longer than Expected, PR-2 Adequacy of Project Funding, and PPM-8 Unplanned Work that Must Be Accommodated. These 4 risk elements together contribute 74 percent of the statistical schedule variance.

3. Operation and maintenance activities were not included in the cost estimate or schedules. Therefore, a full lifecycle risk analysis could not be performed. Risk analysis results or conclusions could be significantly different if the necessary operation and maintenance activities were included.

Table 3. Project Cost Comparison Summary

Confidence Level	Project Cost ($)	Contingency ($)	Contingency (%)
P0	$151,892,000	($627,000)	-0.4%
P5	$172,394,000	$19,875,000	13.0%
P10	$176,093,000	$23,574,000	15.5%
P15	$178,607,000	$26,088,000	17.1%
P20	$180,759,000	$28,240,000	18.5%
P25	$182,512,000	$29,993,000	19.7%
P30	$184,219,000	$31,700,000	20.8%
P35	$185,813,000	$33,294,000	21.8%
P40	$187,292,000	$34,773,000	22.8%
P45	$188,664,000	$36,145,000	23.7%
P50	$190,033,000	$37,514,000	24.6%
P55	$191,402,000	$38,883,000	25.5%
P60	$192,718,000	$40,199,000	26.4%
P65	$194,240,000	$41,721,000	27.4%
P70	$195,759,000	$43,240,000	28.4%
P75	$197,473,000	$44,954,000	29.5%
P80	**$199,411,000**	**$46,892,000**	**30.7%**
P85	$201,604,000	$49,085,000	32.2%
P90	$204,328,000	$51,809,000	34.0%
P95	$208,549,000	$56,030,000	36.7%
P100	$231,528,000	$79,009,000	51.8%

Figure 3. Project Cost Summary

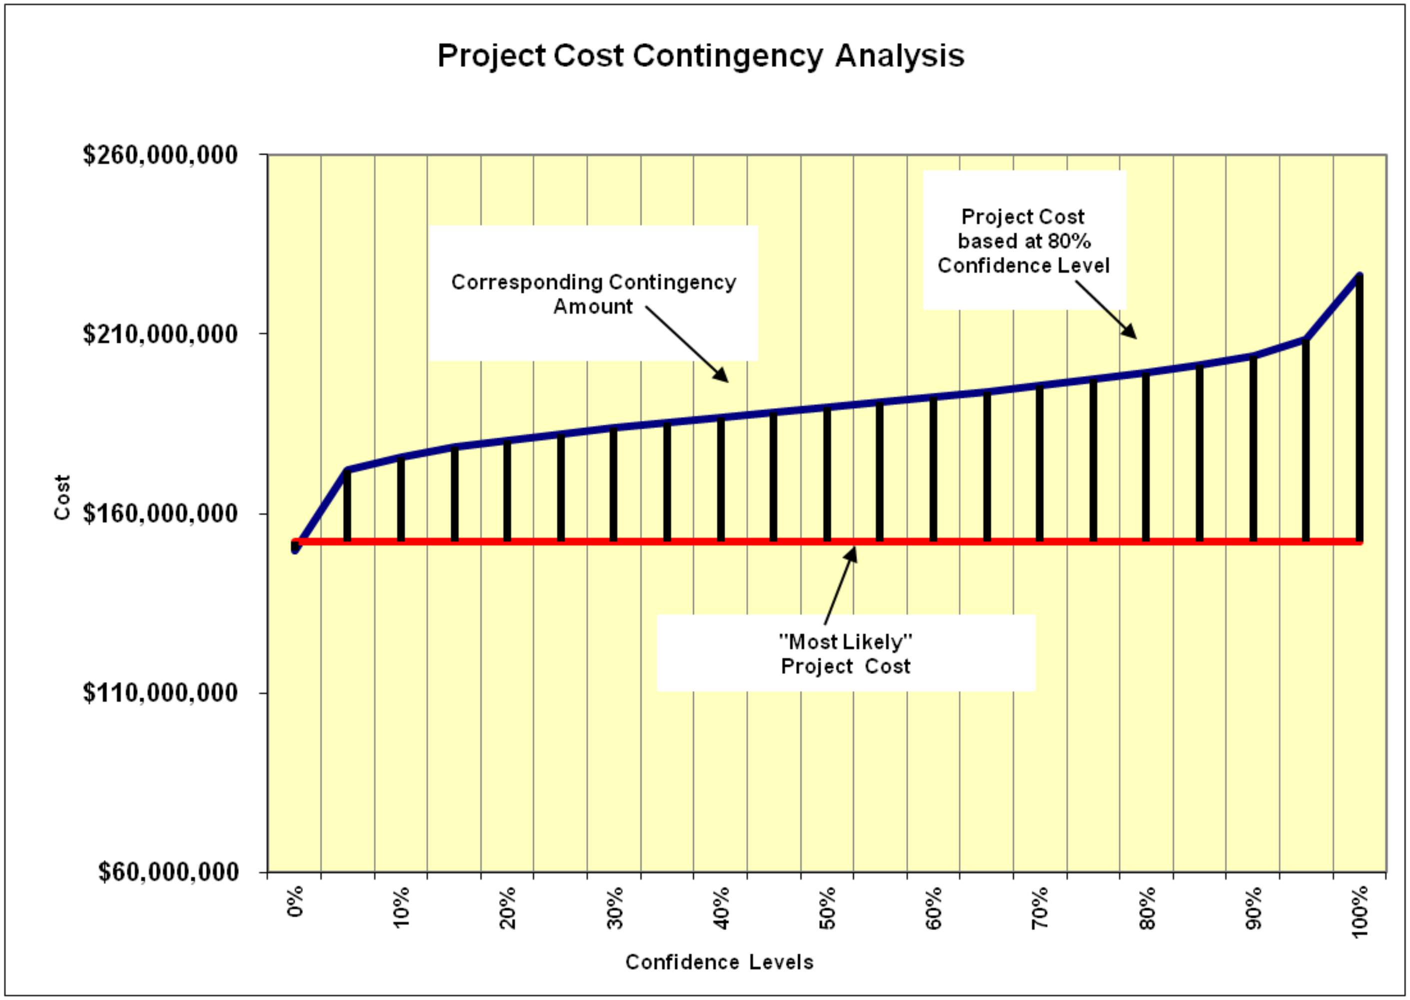

Figure 4. Project Duration Summary

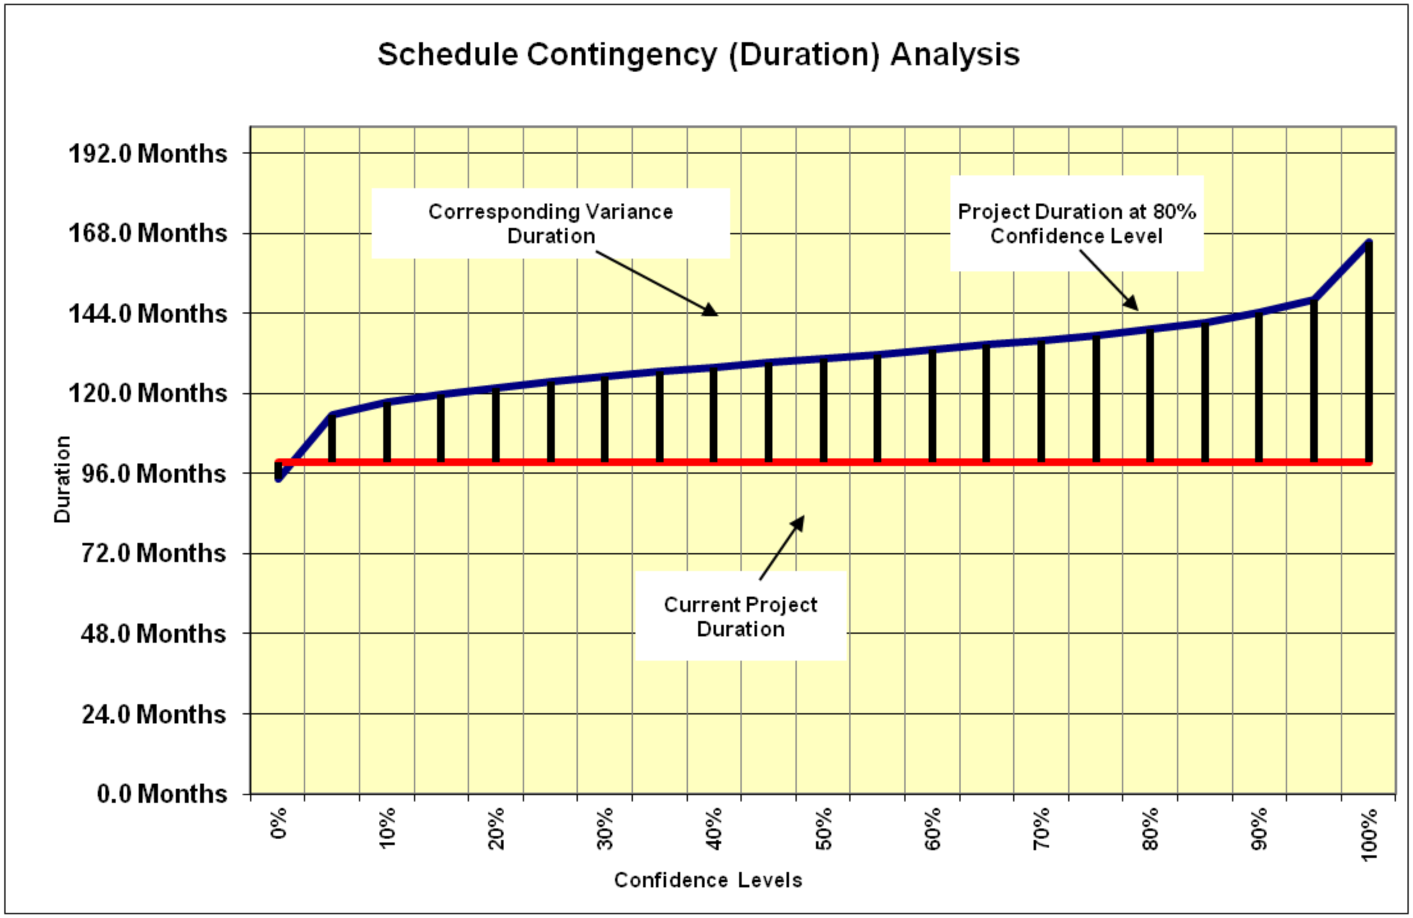

7.2 Recommendations

Risk Management is an all-encompassing, iterative, and life-cycle process of project management. The Project Management Institute's (PMI) *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*, *4th edition*, states that "project risk management includes the processes concerned with conducting risk management planning, identification, analysis, responses, and monitoring and control on a project." Risk identification and analysis are processes within the knowledge area of risk management. Its outputs pertinent to this effort include the risk register, risk quantification (risk analysis model), contingency report, and the sensitivity analysis.

The intended use of these outputs is implementation by the project leadership with respect to risk responses (such as mitigation) and risk monitoring and control. In short, the effectiveness of the project risk management effort requires that proactive management of risks does not conclude with the study completed in this report.

The Cost and Schedule Risk Analysis (CSRA) produced by the PDT identifies issues that require the development of subsequent risk response and mitigation plans. This section provides a list of recommendations for continued management of the risks identified and analyzed in this study. Note that this list is not all inclusive and should not substitute a formal risk management and response plan.

<u>1. Key Cost Risk Drivers</u>: The key cost risk drivers identified through sensitivity analysis were Risks CA-1 Incomplete Acquisition Strategy, CON-1 Stone Quarry Site/Material Availability and Delivery, STL-VEQ (South Jetty) Variation in Estimated Quantities, PR-5 Unexpected Escalation on Stone, PR-7 Market Conditions and Bidding Climate, CA-2 Numerous Separate Contracts These 6 risk elements together contribute over 78 percent of the statistical cost variance.

a. <u>Risk CA-1 Incomplete Acquisition Strategy</u>: The details of the acquisition plan in terms of the technique to let the contracts has not been fully developed. This contributed 21% of the statistical cost variance. Project leadership should take proactive measures to obtain decisions regarding acquisition strategy, as well as communication to management regarding the impact of those decisions on cost performance. Project leadership should develop the acquisition strategy to maximize competition and cost control, and so that current working estimates can capture the probable costs.

b. <u>Risk CON-1 Stone Quarry Site/Material Availability and Delivery</u>: The availability and supply of stone and cranes could be an issue, depending on when the construction occurs and how much is being demanded concurrently. The sheer volume required for this project could overwhelm the local market for supply of stone of this size and quantity. This contributed 17% of the statistical cost variance. Project leadership should conduct market research to determine the regional trends regarding the availability of quarry stone to meet the requirements in parallel to the general market research being conducted. The PDT may also consider changing the engineering requirements or methodologies to increase competition and/or the likelihood of equipment being available.

c. Risk STL-VEQ (South Jetty) Variation in Estimated Quantities: Due to the fact that the project is at a feasibility level, the quantities of stone estimated could change positively or negatively. This contributed 14% of the statistical cost variance. Project leadership should focus the PDT on the engineering details of the recommended plan, improve survey data of actual conditions and geometry of relic stone, and structure and continue engineering efforts to establish detail of design cross section to increase confidence of estimated quantities.

d. Risk PR-5 Unexpected Escalation on Stone: There could be an unusual demand on stone, causing an unexpected spike in pricing. This contributed 11% of the statistical cost variance. External Risk Item are which is generated, caused, or controlled exclusively outside the PDT's sphere of influence. Project leadership should monitor this element and periodically evaluate its effect upon the success of the project.

e. Risk PR-7 Market Conditions and Bidding Climate: There is inherent risk of cost fluctuations created by the contractors available to perform this work, as well as the effects on the market by escalation, especially due to the length of the project. This contributed 9% of the statistical cost variance. External Risk Item are which is generated, caused, or controlled exclusively outside the PDT's sphere of influence. Project leadership should monitor this element and periodically evaluate its effect upon the success of the project.

f. Risk CA-2 Numerous Separate Contracts: There are 4 separate construction contracts planned. Numerous contracts for the project may increase the costs of contracting, and lead to less favorable contract markups, and lack of efficiencies, increasing the construction costs. This contributed 6% of the statistical cost variance. Project leadership should provide resources to support the contracting and administration efforts and look for ways to expand favorable effects and efficiencies to subsequent contracts.

2. Key Schedule Risk Drivers: The key schedule risk drivers identified through sensitivity analysis were Risks TL-1 Variation in Estimated Quantities, RE-5 Agency Actions Take Longer than Expected, PR-2 Adequacy of Project Funding, and PPM-8 Unplanned Work that Must Be Accommodated. These 4 risk elements together contribute 74 percent of the statistical schedule variance.

a. Risk TL-1 Variation in Estimated Quantities: Project leadership should conduct further research and/or survey to validate the quantities estimated within the project scoping documents.

b. Risk RE-5 Agency Actions Take Longer than Expected: Project leadership should coordinate with NMFS and support their process to consultations.

c. Risk PR-2 Adequacy of Project Funding: Project leadership should attempt to develop accurate funding profile projections to capture probable funding requirements. Project leadership may also ensure that the acquisition strategy plan is suited to likely funding scenarios. Ultimately, this is an external risk, and its impacts must be communicated to management.

d. Risk PPM-8 Unplanned Work that Must Be Accommodated: Project leadership should attempt to keep the PDT and reviewers focused on the goals of the project. Leadership should match and monitor schedule and resources for timely design work progression.

3. Risk Management: Project leadership should use of the outputs created during the risk analysis effort as tools in future risk management processes. The risk register should be updated at each major project milestone. The results of the sensitivity analysis may also be used for response planning strategy and development. These tools should be used in conjunction with regular risk review meetings.

4. Risk Analysis Updates: Project leadership should review risk items identified in the original risk register and add others, as required, throughout the project life-cycle. Risks should be reviewed for status and reevaluation (using qualitative measure, at a minimum) and placed on risk management watch lists if any risk's likelihood or impact significantly increases. Project leadership should also be mindful of the potential for secondary (new risks created specifically by the response to an original risk) and residual risks (risks that remain and have unintended impact following response).

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Level

Likelihood of Occurrence	Negligible	Marginal	Significant	Critical	Crisis
Very Likely	Low	Moderate	High	High	High
Likely	Low	Moderate	High	High	High
Unlikely	Low	Low	Moderate	Moderate	High
Very Unlikely	Low	Low	Low	Low	High

Impact or Consequence of Occurrence

Overall Project Scope
See Preferred Plan report for scope.

Cost Impacts
For the MCR Jetties Project, any cost impact of $3 Million or higher should be considered at least "Significant."
Anything over $1.5 Million should be considered at least "Marginal."

Schedule Impacts
For the MCR Jetties Project, any schedule impact of 6 months or greater should be considered at least "Significant."
Anything over 3 months should be considered at least "Marginal."

Risk No.	Risk/Opportunity Event	Concerns	PDT Discussions	UPDATE NOTE:	Project Cost			Project Schedule			Variance Distribution	Correlation to Other(s)	Responsibility/POC
					Likelihood*	Impact*	Risk Level*	Likelihood*	Impact*	Risk Level*			
Contract Risks (Internal Risk Items are those that are generated, caused, or controlled within the PDT's sphere of influence.)													
	PROJECT & PROGRAM MGMT												
PPM-1	Mitigation Features Have not Been Fully Defined	There currently is some cost included for mitigation needs for North Jetty and Jetty A. Total losses that will determine the mitigation plan have not been established, nor the mitigation configuration.	PDT further investigated mitigation requirements. Key PDT members more comfortable with feasibility-level assumptions.	Assumptions modifed to delete items associated with the spur groins and coordinated with Environmental Assessment.	Very Likely	Marginal	MODERATE	Likely	Marginal	MODERATE	Triangular	LD-1	Environmental
PPM-2	Concerns Regarding Trestle Bay Configuration	There is uncertainty as to the ultimate requirements regarding mitigation for Trestle Bay. This may or may not be captured in the estimate.	PDT resolved this issue.		Unlikely	Marginal	LOW	Unlikely	Marginal	LOW	Uniform	TL-5	Environmental
PPM-3	Project Schedule in Question	If the model changes the requirements for configuration in cross-sections, stone size and type, etc., it could alter the currently contemplated schedule. PDT acknowledges that the schedule is not complete.	Upon comprehensive district review, PDT more confident in feasibility level design assumptions.	The MCR jetty system is in a continual state of degredation and the current assumption is to capture a project time period for construction of 2015-2020 in lieu of 2014-2032	Very Likely	Marginal	MODERATE	Very Likely	Marginal	MODERATE	Triangular	CON-4	Project Manager
PPM-4	Issues with Multiple Local Agencies	There are several issues that are in question with respect to local agencies, such as NOAA, DLCD, WDOE, DEQ, NMFS, etc. There are issues with mitigation features, as well as constructability and feasibility of certain features (e.g. the offloading facility)	PDT has conducted several outreach meetings with local agenices and now has a better understanding of their expectations.		Very Likely	Marginal	MODERATE	Very Likely	Marginal	MODERATE	Yes-No		Project Manager
PPM-5	Coordination/Communication Difficulties	There has been some issues and challenges with communication internally, and with external agencies and stakeholders. This is contributed to by the turnover and length of the project formulation.	PDT coordination both internally and externally has improved significantly.		Likely	Marginal	MODERATE	Likely	Marginal	MODERATE	Triangular		Project Manager
PPM-6	Internal Red Tape Causing Delays in Obtaining Approvals and Decisions	The changes to the requirements for reviews (such as ATRs, IEPRs, etc.) has an impact on the performance of the study and the project.	Project's significance will help PDT acquire necessary resources to meet new review requirements.		Likely	Negligible	LOW	Likely	Marginal	MODERATE	Uniform	PPM-8	District Management
PPM-7	Pressure To Deliver on an Accelerated Schedule	There is the possibility that management may pressure the PDT to deliver the project sooner, possibly sacrificing quality. This has already occurred with the environmental aspects of the project.	Could affect both cost and schedule.		Unlikely	Negligible	LOW	Unlikely	Marginal	LOW	Uniform		District Management
PPM-8	Unplanned Work that Must Be Accommodated	If the reviews or the results of models require work to be performed that has not been planned, it could impact cost and schedule.	High priority project; therefore, schedule risk is moderate.		Very Likely	Marginal	MODERATE	Very Likely	Marginal	MODERATE	Uniform	PPM-6	District Management
PPM-9	Product Development by Several Sources	Aspects of the project (e.g. the physical modeling) is being handled outside the District. There is also possibility that some of the PED activities will be performed by AEs. Trying to queue into their workload management cycles could impact the overall schedule.	Could affect schedule.	Added an A/E firm into developing a model and updating the report, creating another layer of coorination activity for the project.	Very Unlikely	Negligible	LOW	Unlikely	Marginal	LOW	Triangular		Project Manager
	CONTRACT ACQUISITION RISKS												
CA-1	Incomplete Acquisition Strategy	The details of the acquisition plan in terms of the technique to let the contracts has not been fully developed.	Key PDT members discussed and decided this risk could be managed with early contracting involvement with project schedule, contingent upon funding.	6/8/12 Cost Impact upgraded to Sign Impact due to resulting High (>$3M) amts of Hi/Low range Upgraded Shedudle Impact level to Significant since High range > 3 mo	Very Likely	Significant	HIGH	Very Likely	Significant	HIGH	Triangular		TASB
CA-2	Numerous Separate Contracts	There could be anywhere from 8 to 18 separate contracts.	Same as above.	Shortening the project time line has decreased the number of construction contracts to 4. High range value greater than $3m so Significant Impact Level	Very Likely	Marginal	MODERATE	Very Likely	Marginal	MODERATE	Triangular		TASB

Risk No.	Risk/Opportunity Event	Concerns	PDT Discussions	UPDATE NOTE:	Project Cost			Project Schedule			Variance Distribution	Correlation to Other(s)	Responsibility/POC
					Likelihood*	Impact*	Risk Level*	Likelihood*	Impact*	Risk Level*			
	TECHNICAL RISKS												
TL-1	Variation in Estimated Quantities	Due to the fact that the project is at a feasibility level, the quantities of stone estimated could change positively or negatively.	Could affect cost and schedule.		Likely	Significant	HIGH	Likely	Significant	HIGH	Triangular		Technical Lead
TL-2	Changes in the Cross-Section Designs	Due to the fact that the project is at a feasibility level, the cross section designs could change.	PDT has a higher level of comfort with feasibility-level design assumptions.		Likely	Marginal	MODERATE	Unlikely	Marginal	LOW	Yes-No		Technical Lead
TL-3	Stone Sizing	There may be some changes in the stone size, as required by the model or in design, as it proceeds. The PDT is fairly confident in the assumptions made at this point. However, due to the size of this project, cost changes are possible.	Could impact costs.		Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Technical Lead
TL-4	Spur Groins	There is some uncertainty as to the stone sizing, the cross-sections, and the methodology for the contemplated spur groins.	Could impact costs.	Spur Groins have been deleted from the preferred plan.	Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Technical Lead
TL-5	Incomplete Studies Regarding Trestle Bay Mitigation	There is a need to accomplish some erosion control and stabilization on the Trestle Bay (Inner Bay) side on the South Jetty. Currently, there are no complete studies for this, and it is now being considered as part of the base (without) project conditions.	PDT resolved this issue.		Unlikely	Negligible	LOW	Unlikely	Negligible	LOW	Triangular	PPM-2	Environmental
TL-6	Wetland Delineations	Wetland delineations for the project are not finalized for any of the jetties.	This risk is very likely to become an issue with minor impacts to cost and schedule.		Very Likely	Negligible	LOW	Very Likely	Negligible	LOW	Triangular		Environmental
NTL-VEQ	NTL-VEQ (North Jetty) Variation in Est. Quantities	Due to the fact that the project is at a feasibility level, the quantities of stone estimated could change positively or negatively.	Could affect cost and schedule.	6/8/12 added back into overall. At this stage of the project this is the apporate way to account for this element since N, S, & A make up the project.	Likely	Significant	HIGH	Likely	Significant	HIGH	Triangular		Technical Lead
NTL-3	NTL3 Stone Sizing (North Jetty)	There may be some changes in the stone size, as required by the model or in design, as it proceeds. The PDT is fairly confident in the assumptions made at this point. However, due to the size of this project, cost changes are possible.	Could impact costs.	6/8/12 added back into overall. At this stage of the project this is the apporate way to account for this element since N, S, & A make up the project.	Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Technical Lead
STL-VEQ	STL -VEQ (South Jetty) Variation in Estimated Quantities	Due to the fact that the project is at a feasibility level, the quantities of stone estimated could change positively or negatively.	Could affect cost and schedule.	6/8/12 added back into overall. At this stage of the project this is the apporate way to account for this element since N, S, & A make up the project.	Likely	Significant	HIGH	Likely	Significant	HIGH	Triangular		Technical Lead
STL-3	STL3 Stone Sizing (South Jetty)	There may be some changes in the stone size, as required by the model or in design, as it proceeds. The PDT is fairly confident in the assumptions made at this point. However, due to the size of this project, cost changes are possible.	Could impact costs.	6/8/12 added back into overall. At this stage of the project this is the apporate way to account for this element since N, S, & A make up the project.	Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Technical Lead
ATL-VEQ	ATL-VEQ (A Jetty) Variation in Estimated Quantities	Due to the fact that the project is at a feasibility level, the quantities of stone estimated could change positively or negatively.	Could affect cost and schedule.	6/8/12 added back into overall. At this stage of the project this is the apporate way to account for this element since N, S, & A make up the project. Total $ impact <$3M on high reevalt to Marginal impact	Likely	Marginal	MODERATE	Likely	Significant	HIGH	Triangular		Technical Lead
ATL-3	ATL3 Stone Sizing (A Jetty)	There may be some changes in the stone size, as required by the model or in design, as it proceeds. The PDT is fairly confident in the assumptions made at this point. However, due to the size of this project, cost changes are possible.	Could impact costs.	6/8/12 added back into overall. At this stage of the project this is the apporate way to account for this element since N, S, & A make up the project. High $ Impact <$1.5M re-ranked to Negligible impact	Likely	Negligible	LOW	Very Unlikely	Negligible	LOW	Triangular		Technical Lead
	LANDS AND DAMAGES RISKS												
LD-1	Mitigation Needs Undefined	Because the mitigation measures have not been fully defined, the real estate requirements also have not been defined.	Could affect cost and schedule.	Mitigation quantities updated to match EA but are still not very defined.	Very Likely	Marginal	MODERATE	Unlikely	Negligible	LOW	Uniform	PPM-1	Real Estate
LD-2	Roadway Repair Requirements	There may be requirements to repair roadways due to the wear caused by project transportation requirements.	This would be nominal cost, but would accrue over 18 years.	The construction timeline has been reduced to 6 years but the scope of work is still unknown.	Very Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Project Manager
LD-3	Lands and Damages Not Included in Estimate	Lands, Relocations, and Damages (LERDs) have not been captured in the baseline cost estimate. Upland site restoration besides wetland and waters mitigation may be challenging given the need for repeated access over a long construction schedule.	Could impact project costs.		Likely	Marginal	MODERATE	Likely	Negligible	LOW	Triangular		Cost Engineering
	REGULATORY AND ENVIRONMENTAL RISKS												
RE-1	Potential Barging Windows	There is a possibility that barging window (limitations) could be induced resulting from studies occurring for ongoing projects of a similar nature.	Could affect cost and schedule.		Unlikely	Marginal	LOW	Unlikely	Marginal	LOW	Yes-No	CON-2	Environmental

Risk No.	Risk/Opportunity Event	Concerns	PDT Discussions	UPDATE NOTE:	Project Cost			Project Schedule			Variance Distribution	Correlation to Other(s)	Responsibility/POC
					Likelihood*	Impact*	Risk Level*	Likelihood*	Impact*	Risk Level*			
RE-2	Impact to Wetland by Culvert Design	The ultimate culvert design may have some impacts on the wetland. The drain field and culvert repair for the North Jetty lagoon fill are not finalized. Some level of hydrologic and/or hydraulic analyses are needed to determine if there will be impacts to adjacent wetlands. If impacts are anticipated, this will increase the amount of mitigation needed, which could increase cost.	With proper design, it is unlikely there would be additional impacts. This may have marginal impact on budget due to increased mitigation costs, but should not have a significant impact to schedule. The need for a simple hydrologic evaluation is very likely, and could have a marginal impact on budget and not likely to have an impact on schedule.		Likely	Marginal	MODERATE	Unlikely	Negligible	LOW	Uniform		Environmental
RE-3	Project in a Coastal Zone	This project will require clearances from local agencies due to the fact that it is in a Coastal Zone. PDT will have to obtain a consistency determination by the Coastal Zone Management (DLCD).	Could affect cost (if methodology in offloading is required) and schedule.		Likely	Marginal	MODERATE	Unlikely	Marginal	LOW	Uniform		Project Manager
RE-4	Status of Permits	There may be some challenges in obtaining permits due to increased requirements by outside agencies, such as NMFS, that incur extra costs.	Could affect costs.		Unlikely	Marginal	LOW	Unlikely	Marginal	LOW	Triangular		Project Manager
RE-5	Agency Actions Take Longer than Expected	NMFS has not completed their BIOP for the project, and the PDT has no control over the completion of that effort, which could delay implementation.	Could impact schedule.	Biop complete but are required to have a separate consultation for 71 habitat improvements.	Likely	Marginal	MODERATE	Likely	Significant	HIGH	Uniform	RE-6	Project Manager
RE-6	Requirements Added by NMFS	Due to the extensive nature of this rehab, there is the potential that additional mitigation could be required.	Could affect cost and schedule.		Likely	Marginal	MODERATE	Unlikely	Marginal	LOW	Uniform	RE-5	Project Manager
RE-7	Recurring Permits Required	The project is very likely to require new permits every 5 years.	Could impact schedule.		Very Likely	Negligible	LOW	Likely	Marginal	MODERATE	Yes-No		Project Manager
	CONSTRUCTION RISKS												
CON-1	Stone Quarry Site/Material Availability and Delivery	The availability and supply of stone (and cranes) could be an issue, depending on when the construction occurs and how much is being demanded concurrently. The sheer volume required for this project could overwhelm the local market for supply of stone of this size and quantity.	The cost estimator, the design engineer, resident engineer, and PM agreed that based on the current revised construction schedule, this risk was moderate for both cost and schedule.	6/8/12 Upgraded cost impact to Significant since High range turns out to be >$3M	Likely	Significant	HIGH	Likely	Marginal	MODERATE	Triangular		Cost Engineering
CON-2	Concerns with the Offloading Facility	There is only one off-loading facility for each of the jetties. This could present a contract sequence/strategy plan such that the resource is properly managed under separate contracts, even working separable features of work.	This could affect cost and schedule.		Unlikely	Marginal	LOW	Unlikely	Marginal	LOW	Yes-No		Project Manager
CON-3	Transportation/haul routes constricted or unusable during periods of time	There may be some transportation routes that are unusable or shut-down at certain times of year. Also, there is constricted access, especially for the amount of traffic anticipated.	This risk and assumption is reflected in the cost estimate.		Unlikely	Marginal	LOW	Unlikely	Marginal	LOW	Triangular		Technical Lead
CON-4	Adequacy of Construction Schedule	The construction schedule is very preliminary in nature.	The cost estimator, the design engineer, resident engineer, and PM agreed that based on the current revised construction schedule, this risk was moderate for both cost and schedule.	The schedule overall duration has been shortened and thus reduces the schedule risk.	Unlikely	Marginal	LOW	Very Likely	Marginal	MODERATE	Triangular	PPM-3	Technical Lead
CON-5	Critical Fabrication and Delivery	If the project required concrete armor units, there would be potential risk in securing fabrication and ensuring timely delivery.	PDT does not feel that the quantities would present a huge risk that could not be supported by the market.	Market research has indicated a single stone supplier will be able to furnish 200,000 tons of rock per construction season.	Unlikely	Marginal	LOW	Unlikely	Marginal	LOW	Triangular		Cost Engineering
CON-6	Consideration for Post Award Cost Modifications	There is inherent risk of cost growth following award of construction contracts due to post-award contract modifications due to differing site conditions, user-directed changes, or engineering changes during construction. This risk was added during the ATR of the cost estimate, schedule, and risk analysis.	Historically, this risk always adds at least moderate cost growth to contract cost. Since this contract is largely constrained by work windows, it is likely that modifications would be structured in ways to minimize schedule impacts or accelerate work such that modifications did not affect contract schedule.	6/8/12 Upgraded cost impact to Significant since High range turns out to be >$3M	Likely	Significant	HIGH	Unlikely	Negligible	LOW	Triangular		Construction
	ESTIMATE AND SCHEDULE RISKS												
EST-1	Unit Costs for Stone In Question	The latest estimate had lower costs for stone than the previous version. The PDT feels that the unit prices for stone may be on the optimistic side.	Design engineer accounted for this risk factor within project model.		Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Cost Engineering
EST-2	Special Equipment Assumptions	The latest estimate includes a smaller crane than that of another similar project. This may be too optimistic. This project requires several pieces of specialized equipment for transportation and placement. There may be issues related to assumptions in the design/estimate, as well as availability issues.	PDT discussions regarding constructibility issues have lessened this cost risk.		Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Triangular		Cost Engineering
EST-3	Estimate Excludes Contingency and Escalation	At this time, the current working estimate does not include contingency and escalation. This will be captured by the risk analysis.	This will not impact costs or schedule, as impacts will be captured by the risk analysis.		Very Unlikely	Negligible	LOW	Very Unlikely	Negligible	LOW	Triangular		Cost Engineering

Risk No.	Risk/Opportunity Event	Concerns	PDT Discussions	UPDATE NOTE:	Project Cost			Project Schedule			Variance Distribution	Correlation to Other(s)	Responsibility/POC
					Likelihood*	Impact*	Risk Level*	Likelihood*	Impact*	Risk Level*			
EST-4	Schedule Depicts Logical Construction Sequencing, Phasing, and Parallel Activities	Due to the size of this job, there is considerable opportunity for issues or opportunities with the sequencing, phasing, and parallel activities.	The most critical issues with schedule relate to site access (road replacement) and the annual work windows. Due to the work window, even minor delays could significantly delay the project, pushing work off to the following year, and necessitating rework in subsequent years. Could positively or negatively affect cost and/or schedule. Key PDT members decided this is a moderate risk to cost and schedule.		Likely	Marginal	MODERATE	Likely	Marginal	MODERATE	Triangular		Technical Lead
EST-5	Productivity of Contractor Labor and Equipment	The estimate captures assumptions regarding contractor's productivity rates for labor and equipment built into the crews and assemblies in the estimate. However, actual productivity during construction could vary. This risk was added during the ATR of the cost estimate, schedule, and risk analysis.	Variance in the assumed producitivity rates could affect the construction contract costs and schedule.		Unlikely	Significant	MODERATE	Unlikely	Significant	MODERATE	Triangular		Cost Engineering
	Programmatic Risks (External Risk Items outside the PDT's sphere of												
PR-1	Fuel Prices	There is potential for significant increase in fuel prices, especially due to the length of the project.	About 80 percent of project costs are related to stone procurement. Key PDT members decided this is a marginal cost risk.		Likely	Marginal	MODERATE	Very Unlikely	Negligible	LOW	Min. Extreme		Cost Engineering
PR-2	Adequacy of Project Funding	The current working estimate and schedule assumes obtaining outlays in an anticipated schedule and funding profile. The issue is that if the timing and outlay amounts differ from the plan, it could alter the scope and scheme of implementation.	Could affect cost and schedule.		Likely	Significant	HIGH	Likely	Significant	HIGH	Uniform		Project Manager
PR-3	Introduction of New Constraints/Requirements	Due to the length of the project, there is the possibility of new regulatory or mitigation requirements being applied.	Key PDT members reassesed and base on communciations with regulatory agencies, decided this is a moderate cost and schedule risk.		Likely	Marginal	MODERATE	Likely	Marginal	MODERATE	Triangular		Project Manager
PR-4	Local Communities Pose Objections	Due to the length of the project, there is the possibility of objections growing from the local communities.	Feedback during EA public meeting was favorable; therefore, it's reasonable to rate schedule risk as moderate.	The EA is being revised and sent out for another round of public comments. The risk to cost and schedule remains moderate.	Likely	Marginal	MODERATE	Likely	Marginal	MODERATE	Uniform		Project Manager
PR-5	Unexpected Escalation on Stone	There could be an unusual demand on stone, causing an unexpected spike in pricing.	Key PDT members decided this cost risk is moderate based on excess capacity of quarries.	High range value greater than $3m so Significant Impact Level	Likely	Significant	HIGH	Unlikely	Marginal	LOW	Triangular		Cost Engineering
PR-6	Unanticipated Repairs Necessary on Jetties	A breach or failure on any of the jetties could tie up resources for the completion of this project.	This is not seen as a risk that would impact this project, as emergency repairs would be funded separately.		Very Likely	Negligible	LOW	Very Unlikely	Negligible	LOW	Yes-No		Project Manager
PR-7	Market Conditions and Bidding Climate	There is inherent risk of cost fluctuations created by the contractors available to perform this work, as well as the effects on the market by escalation, especially due to the length of the project.	Key PDT members decided this cost risk is moderate based on excess capacity of quarries.	6/8/12 Upgraded cost impact to Significant since High range turns out to be >$3M	Likely	Significant	HIGH	Very Unlikely	Negligible	LOW	Triangular		Cost Engineering

*Likelihood, Impact, and Risk Level to be verified through market research and analysis (conducted by cost engineer).

1. Risk/Opportunity identified with reference to the Risk Identification Checklist and through deliberation and study of the PDT.
2. Discussions and Concerns elaborates on Risk/Opportunity Events and includes any assumptions or findings (should contain information pertinent to eventual study and analysis of event's impact to project).
3. Likelihood is a measure of the probability of the event occurring -- **Very Unlikely**, **Unlikely**, **Moderately Likely**, **Likely**, **Very Likely.** The likelihood of the event will be the same for both Cost and Schedule, regardless of impact.
4. Impact is a measure of the event's effect on project objectives with relation to scope, cost, and/or schedule -- **Negligible**, **Marginal**, **Significant**, **Critical**, or **Crisis.** Impacts on Project Cost may vary in severity from impacts on Project Schedule.
5. Risk Level is the resultant of Likelihood and Impact **Low**, **Moderate**, or **High**. Refer to the matrix located at top of page.
6. Variance Distribution refers to the behavior of the individual risk item with respect to its potential effects on Project Cost and Schedule. For example, an item with clearly defined parameters and a solid most likely scenario would probably follow a triangular or normal distribution. A risk item for which the PDT has little data or probability of modeling with respect to effects on cost or schedule (i.e. "anyone's guess") would probably follow a uniform or discrete uniform distribution.
7. The responsibility or POC is the entity responsible as the Subject Matter Expert (SME) for action, monitoring, or information on the PDT for the identified risk or opportunity.
8. Correlation recognizes those risk events that may be related to one another. Care should be given to ensure the risks are handled correctly without a "double counting."
9. Affected Project Component identifies the specific item of the project to which the risk directly or strongly correlates.
10. Project Implications identifies whether or not the risk item affects project cost, project schedule, or both. The PDT is responsible for conducting studies for both Project Cost and for Project Schedule.
11. Results of the risk identification process are studied and further developed by the Cost Engineer, then analyzed through the Monte Carlo Analysis Method for Cost (Contingency) and Schedule (Escalation) Growth.

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

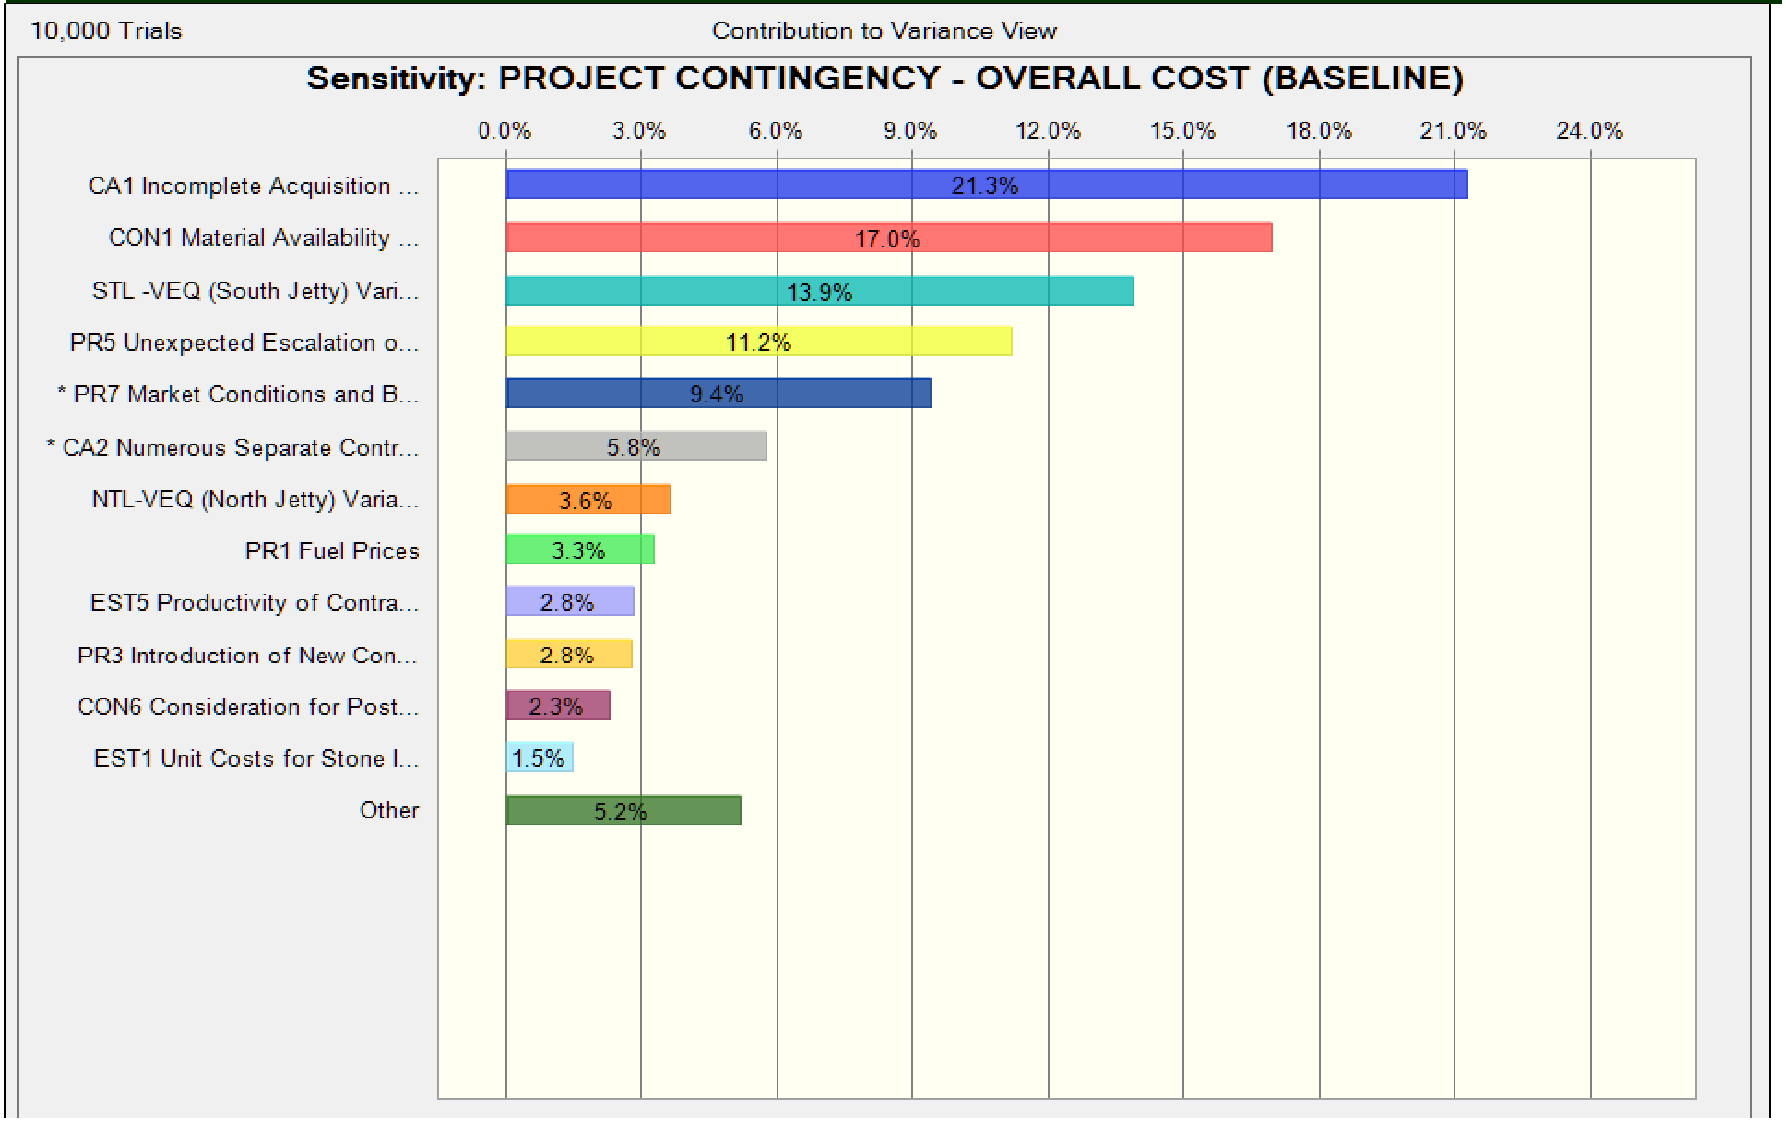
MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12



MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-1	Mitigation Features Have not Been Fully Defined	($718,695)	$0	$1,796,738
		$2,874,781	$3,593,476	$5,390,214

Notes: This item captures the risk that the ultimate configuration of the mitigation features will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes less area will be impacted by the construction activities. Assume a 20% reduction from the most likely.

High High assumes more mitigation may be required due to the multiple years of construction which could required intermin mitigation actions. Assume 50% higher costs.

From MII 120608 w/ mitig. Acre matching EA

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-5	Coordination/Communication Difficulties	$0	$0	$1,942,400

Notes: This item captures the risk that coordination and communication difficulties will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes no change from the baseline estimate.

High High assumes that coordination and communication difficulties increase the cost of PED by up to 10%.

Update with "MCR TPCS 120608.xlsx"

	Current	Worst Case
Total Construction Costs	$152,519,000	
30 Account (PED) from TPCS 4/24/12	$19,424,000	$21,366,400
Difference		**$1,942,400**

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-8	Unplanned Work that Must Be Accommodated	$0	$0	$1,666,600

Notes: This item captures the risk that unplanned work will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes no change from the baseline estimate.

High High assumes that unplanned work that must be accommodated during the review and development phases could increase the costs of PED by up to 10%.

Update with "MCR TPCS 120608.xlsx"

	Current	Worst Case
Total Construction Costs	$152,519,000	
30 Account (PED) from TPCS 6/08/12	$16,666,000	$18,332,600
Difference		**$1,666,600**

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
CA-1	Incomplete Acquisition Strategy	($7,625,950)	$0	$15,251,900
		$144,893,050	$152,519,000	$167,770,900

Notes: This item captures the risk that lack of acquisition strategy planning will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes that the ultimate acquisition strategy could lead to more favorable contract situations, saving up to 5% from the currently contemplated construction costs.

High

High assumes that the ultimate acquisition strategy could lead to less favorable contracting situations, increasing the construction costs by up to 10%.

Update with "MCR TPCS 120608.xlsx"

Risk Refer No.	Risk Event	Low	Most Likely	High
CA-2	Numerous Separate Contracts	$0	$0	$7,625,950
		$152,519,000	$152,519,000	$160,144,950

Notes: This item captures the risk that having numerous separate contracts will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes no change from the baseline estimate.

High High assumes that having numerous contracts for the project may increase the costs of contracting, and lead to less favorable contract markups, and lack of efficiencies, increasing the construction costs by 5%.

Update with "MCR TPCS 120608.xlsx"

MCR Jetties Rehabilitation Feasibility Report - PDT Risk Register - North Jetty

Risk Refer No.	Risk Event	Low	Most Likely	High
NTL-VEQ	Variation in Estimated Quantities (North Jetty)	($4,487,338)	$0	$5,983,117

	Current	Best Case	Worst Case

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
LD-1	Mitigation Needs Undefined	$0	$0	$1,500,000

Notes: This item captures the risk that lack of information regarding mitigation needs (for real estate footprint) will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes no change from the baseline estimate.

High

High assumes that mitigation needs reveal the requirement to purchase a significant amount of real estate, costing up to $1.5 Million (based on input from the PDT).

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
LD-2	Roadway Repair Requirements	$0	$0	$1,500,000

Notes: This item captures the risk that roadway repair requirements to support the contract will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes no change from the baseline estimate.

High High assumes that significant roadway repairs are necessary over the lifetime of the project, costing up to $1.5 Million (based on input from the PDT).

Risk Refer No.	Risk Event	Low	Most Likely	High
LD-3	Lands and Damages Not Included in Estimate	$0	$0	$1,500,000

Notes: This item captures the risk that not having the lands and damages in the current estimate will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes no change from the baseline estimate.

High High assumes that not having a real estate estimate could increase the overall project cost by up to $1.5 Million (based on input from the PDT).

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
RE-2	Impact to Wetland by Culvert Design	($179,674)	$0	$1,078,043
		$3,413,802	$3,593,476	$4,671,519

Notes: This item captures the risk that impacts to wetlands by the culvert design will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes less impact than anticipated, saving up to 5% from the mitigation costs.

High High assumes more impact that anticipated, costing up to 30% more than currently estimated for mitigation.

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
RE-6	Requirements Added by NMFS	$0	$0	$2,500,000

Notes: This item captures the risk that requirements added by NMFS will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes no change from the baseline estimate.

High High assumes that NMFS requires more mitigation than currently estimated, adding up to $2.5 Million in costs (value based on historical experience).

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
CON-1	Material Availability and Delivery	($4,870,856)	$0	$14,612,567
		$92,546,258	$97,417,114	$112,029,681

Notes:	This item captures the risk that material availability and delivery will cause a variance from the current baseline estimate.
Likely	Likely assumes no change from the baseline estimate.
Low	Low assumes delivery from one source. Assume possible 5% decrease in transportation costs.
High	High assumes multiple sources with longer delivery routes. Assume a 15% increase due to transportation costs. Update with "MCR TPCS 120608.xlsx" Direct Matl cost of $78,051,280 * Markup of 1.246

Risk Refer No.	Risk Event	Low	Most Likely	High
CON-6	Consideration for Post Award Cost Modifications	$0	$0	$7,625,950
		$152,519,000	$152,519,000	$160,144,950

Notes: This item captures the risk that post-award contract modifications will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumed no change from the baseline estimate.

High High assumes up to 5% of the estimated contract cost for post-award contract modifications, based on historical metrics and rules of thumb.

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
EST-1	Unit Costs for Stone In Question	($2,590,444)	$0	$3,281,878
		$94,794,664	$97,385,108	$100,666,986

Notes: This item captures the risk that not having accurate unit costs for stone will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate. UPDATE 06/08/12 update with Material cost from MII estimate

Low Low assumes with a avg direct cost of $121/ton. Assume the cost is $5/ton less.

High High assumes a $20 increase per ton due to availability and possible longer delivery routes.
Update with "MCR TPCS 120608.xlsx"
Direct Matl cost of $78,051,280 * Markup of 1.246

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
EST-2	Special Equipment Assumptions	($1,494,940)	$0	$2,989,880
		$28,403,863	$29,898,803	$32,888,683

Notes: This item captures the risk that inaccurate assumptions regarding special equipment will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes estimate has oversized equipment. Assume 5% reduction, due to gaining efficiencies based on decreased equipment costs for operation and mobilization.

High High assumes larger equipement is required for the upper range of stone. This would increase equipement costs as well are mob/demb costs. Assume 10% increase due to efficiency loss and additional mobilization.

Update with "MCR TPCS 120608.xlsx"

10 BREAKWATERS AND SEAWALLS

Equipment Costs Direct	$23,963,005
Equipment cost w/ Gen MU	**$29,898,803**

Update with "MCR TPCS 120608.xlsx"

Total Extended Costs Direct	122,239,462
Total Extended Costs Contract	152,519,000
General Total markup	1.248

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
EST-5	Productivity of Contractor Labor and Equipment	($2,755,157)	$0	$5,510,313
		$52,347,977	$55,103,134	$60,613,447

Notes: This item captures the risk that inaccurate assumptions regarding special equipment will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes that productivity is up to 5% better than estimated in the baseline estimate, due to procuring a highly efficient contractor.

High

High assumes that productivity is up to 10% decreased than currently estimated, due to procuring a less efficient contractor.

	direct	Total w/ 1.246 MU
update with file "MCR Preferred Plan 120608.mlp" Productivity affects Labor & Equip Cost but not matl		
total MII cost		$152,519,000

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-1	Fuel Prices	$0	$0	$7,807,497
			$29,898,803	$37,706,300

Notes: This item captures the risk that fuel prices will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate. Estimate used current price of $3.95 road & $3.37 offroad diesel, and $3.67/ gal gasoline.

Low Low assumes no change from the most likely cost of fuel.

High High assumes fuel prices that fuel prices could double to up to $7.90/gallon for on-road diesel and $6.74/gal off road and $7.34/gal.

Update 06/08/12 used total direct equipment costs of new MII estimate x MU 1.246 (see Ref. EST-2) w/ $3.95/gal, $3.37, 3.67 vs. $7.90/gal, 6.74, 7.34

		direct	1.248
Equipment costs	**@ $3.95/gal road diesel**	**23,963,005**	**29,898,803**

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-3	Introduction of New Constraints/Requirements	$0	$0	$7,625,950
			$152,519,000	$160,144,950

Notes: This item captures the risk that the introduction of new constraints or requirements will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes no change from the baseline estimate.

High

High assumes that new constraints or requirements are required, increasing the overall project cost by up to 5% to cover environmental/regulatory considerations not currently contemplated.

Update with "MCR TPCS 120608.xlsx"

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-4	Local Communities Pose Objections	$0	$0	$1,500,000

Notes: This item captures the risk that local communities posing objections will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low Low assumes no change from the baseline estimate.

High High assumes that if local communities pose objections, it could add up to $1.5 Million in costs (based on input from the PDT).

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-5	Unexpected Escalation on Stone	$0	$0	$14,370,518
		$105,872,920	$105,872,920	$120,243,438

Notes: This item captures the risk that unexpected escalation on the price of stone will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes the cost of stone will not change from the most likely case.

High

High assumes an escalation on stone of up to 3% per year (over and above national/local market average inflation for materials).

Update 6/08/12 with matl Direct costs from MII file "MCR Preferred Plan 120608.mlp"

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-7	Market Conditions and Bidding Climate	($7,625,950)	$0	$15,251,900
		$144,893,050	$152,519,000	$167,770,900

Notes: This item captures the risk that market conditions and bidding climate will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes that market prices are better than anticipated, saving up to 5% in construction costs.

High

High assumes that market forces make the overall project cost up to 10% more expensive.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-1	Mitigation Features Have not Been Fully Defined	-2.0 Months	0.0 Months	4.0 Months

Notes: This item captures the risk that the ultimate configuration of the mitigation features will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes that the ultimate configuration of the mitigation features will be less robust that currently contemplated, improving the schedule by up to 2 months.

High

High assumes that the ultimate configuration of the mitigation features will be more robust that currently contemplated, delaying the schedule by up to 4 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-3	Project Schedule in Question	-3.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that eventual project schedule will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes that the ultimate execution of the schedule is more effective than currently contemplated, improving the schedule by up to 3 months.

High

High assumes that the ultimate execution of the schedule is less effective than currently contemplated, delaying the schedule by up to 6 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-4	Issues with Multiple Local Agencies	0.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that issues with local agencies will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes no change from the baseline schedule.

High High assumes that issues with local agencies delay the project by up to 6 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-5	Coordination/Communication Difficulties	-2.0 Months	0.0 Months	4.0 Months

Notes: This item captures the risk that coordination and communication difficulties will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes that coordination and communication are more effective than currently contemplated, improving the overall schedule by up to 2 months.

High

High assumes that coordination and communication are less effective than currently contemplated, delaying the overall schedule by up to 4 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-6	Internal Red Tape Causing Delays in Obtaining Approvals and Decisions	0.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that internal red tape in obtaining approvals and decisions will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes no change from the baseline schedule.

High High assumes internal red tape in obtaining approvals and decisions delay the project by up to 6 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PPM-8	Unplanned Work that Must Be Accommodated	-3.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that unplanned work will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes that changes to the overall work scope due to unplanned work may actually reduce scope, eliminating up to 3 months from the overall schedule.

High

High assumes that changes to the overall work scope due to unplanned work may increase scope, adding up to 6 months from the overall schedule.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
CA-1	Incomplete Acquisition Strategy	-3.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that lack of acquisition strategy planning will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes that the lack of acquisition strategy planning may actually produce more favorable contracting and sequencing that currently contemplated, improving the schedule by up to 3 months.

High High assumes that the lack of acquisition strategy planning may produce less favorable contracting and sequencing that currently contemplated, delaying the schedule by up to 6 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
CA-2	Numerous Separate Contracts	0.0 Months	0.0 Months	4.0 Months

Notes: This item captures the risk that having numerous separate contracts will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes no change from the baseline schedule.

High

High assumes that more there will be at least 20-25 separate contract, adding up to one year of cumulative delay due to contract actions and sequencing issues.

Update 120424 Plan time frame reduced to 6 years with only 4 contracts
Cumulative delay assumed to be 1 months each contract for 4 mo

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
TL-1	Variation in Estimated Quantities	-14.9 Months	0.0 Months	19.8 Months
		84.2	99.0	118.8

Notes: This item captures the risk that variation in estimated quantities will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes the ultimate quantities could be significantly less than contemplated, leading to a quantity reduction of up to 15% (per FAR clause 52.211-18 IAW Section 11.703c), decreasing the overall project time by up to 15%.

High

High assumes that the worst case is up to 20% additional quantity, increasing the overall project time up to 20%.

UPDATE 120424 Update total schedule length to 99 months (Start 9/3/12 to end of 5/2/20 plus 182 days of work that year)

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
RE-5	Agency Actions Take Longer than Expected	0.0 Months	0.0 Months	12.0 Months

Notes: This item captures the risk that agency actions taking longer than expected will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes no change from the baseline schedule.

High High assumes that issues with approval of the BIOP could delay the project by up one year.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
RE-7	Recurring Permits Required	0.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that requirements to obtain permits repeatedly throughout the project will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes no change from the baseline schedule.

High High assumes that issues with obtaining recurring permits could delay the overall project by up to 6 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
CON-1	Material Availability and Delivery	-2.0 Months	0.0 Months	4.0 Months

Notes: This item captures the risk that material availability and delivery will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes that material is readily available for timely delivery, improving the overall schedule by up to 2 months.

High

High assumes that there are challenges with the availability and delivery of material, delaying the overall project by up to 4 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
CON-4	Adequacy of Construction Schedule	-1.5 Months	0.0 Months	3.0 Months

Notes: This item captures the risk that uncertainty regarding the accuracy of the construction schedule will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes that the ultimate contractors will perform more efficiently than anticipated on the current construction schedule, improving the overall project schedule by up to 3 months.

High High assumes that the current construction schedule does not adequately capture how ultimate contractors will perform, resulting in delay in the overall project schedule by up to 6 months.

Update 120424. Total plan is about half duration of previous. Reduce Hi/lows from -3 to +6 mo to -1.5 to +3 mo

MCR Jetties Rehabilitation Feasibility Report - Cost and Schedule Risk Analysis Revised 06/08/12

Risk Refer No.	Risk Event	Low	Most Likely	High
EST-5	Productivity of Contractor Labor and Equipment	-2.0 Months	0.0 Months	4.0 Months
		38.3	40.3	44.3

Notes: This item captures the risk that inaccurate assumptions regarding special equipment will cause a variance from the current baseline estimate.

Likely Likely assumes no change from the baseline estimate.

Low

Low assumes that productivity is up to 5% better than estimated, saving up to 2 months (calculated as duration deltas).

High

High assumes that productivity is up to 10% decreased than currently estimated, adding up to 4 months (calculated as duration deltas).

Update 120424 used different work task with more detailed equipment so total equipment hour not easily tell project duration. Base on new schedule for duration of Contruction activities

	Days Construct Activities
2014 N Jetty	95
2015 Jetty A	181
2015 N Jetty	128
2016 N Jetty	123

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-2	Adequacy of Project Funding	0.0 Months	0.0 Months	12.0 Months

Notes: This item captures the risk that the adequacy of project funding will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low

Low assumes no change from the baseline schedule.

High High assumes that challenges in receiving adequate funding in the increments anticipated could lead to an overall project delay of up to 2 years (due to the narrow construction windows each season).

Update assume overall delay of up to 1 year since updated total duration is about half previous plan

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-3	Introduction of New Constraints/Requirements	0.0 Months	0.0 Months	6.0 Months

Notes: This item captures the risk that the introduction of new constraints or requirements will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes no change from the baseline schedule.

High High assumes the introduction of new constraints or requirements could dleay the overall project schedule by up to 6 months.

MCR Jetties Rehabilitation Feasibility Report OVERALL Schedule Risk Analysis Model

Risk Refer No.	Risk Event	Low	Most Likely	High
PR-4	Local Communities Pose Objections	0.0 Months	0.0 Months	3.0 Months

Notes: This item captures the risk that local communities posing objections will cause a variance from the current baseline schedule.

Likely Likely assumes no change from the baseline schedule.

Low Low assumes no change from the baseline schedule.

High High assumes that local communities posing objections could delay the overall project by up to 3 months.

MCR Jetties Rehabilitation Feasibility Report - SCHEDULE Risk Analysis Model UPDATE 120608
Schedule Roll-up
6/8/2012
Taken from file: "MCR Construction Schedule 120418.pdf"

Task Name	Duration (Days)	Start date		
MCR Long Term Planning Rpt	586	5/24/2010		
2014 Construction Contract 1	535	9/3/2012	99.3	total months to

					PROJECT NOTES - (General Construction Details and Narrative)	
				NOTE	**Basis of Cost Estimate Notes**	**REVIEW COMMENTS**
X				**NOTE 1**	Project and Top Folder notes notes present a clear understanding and scope definition.	
X				**NOTE 2**	Scope presented in the project notes is consistent with the scope of the documents for the corresponding plan.	
X				**NOTE 3**	Major project construction features clearly identified in the estimate subfolders.	
X				**NOTE 4**	Top Folder notes clarify major assumptions such as acquisition strategy, expected bid competition, prime and subcontractor assignments, major cost quotes, major construction processes, construction phasing and/or sequencing.	
X				**NOTE 5**	Top Folder notes address significant or high-risk cost items in the project scope.	
X				**NOTE 6**	Notes are adequate to convey project scope and estimate assumptions.	
					Construction Estimate Notes on Critical Costs	**REVIEW COMMENTS**
X				**NOTE 8**	General assumptions noted in the project notes and whether they seem reasonable.	
X				**NOTE 9**	Folder notes provide basis of estimate related to assumptions, quotes, and historical data?	
X				**NOTE 10**	Site and project access considered and presented in the notes.	
X				**NOTE 11**	Critical material sources identified and supported by research.	
X				**NOTE 12**	Unusual construction conditions considered and documented (e.g., studies, geotechnical data, borrow sources, water and water diversion, and weather).	
X				**NOTE 13**	Unique construction techniques considered, documented and reasonable.	
X				**NOTE 14**	Environmental concerns addressed impacting construction activities.	
X				**NOTE 15**	Acquisition Plan identified and matches the estimate structure.	
X				**NOTE 16**	Subcontracting plan and subcontract crafts identified.	Limited subcontractors due to rock delivery cost included in material price of rock.
X				**NOTE 17**	Effective dates for pricing labor, equipment, and material are current.	
				EST	**GENERAL ESTIMATE LAYOUT - Title Structure (Work Breakdown Structure)**	
X				**EST 1**	Estimate developed in proper Work Breakdown Structure (WBS) format in accordance with all guidelines (ETL 1110-2-573).	
X				**EST 2**	Folder title structure and the descriptions adequate to determine what is being estimated.	
X				**EST 3**	WBS adequately reflects all project scope	
X				**EST 4**	Prime and subcontractor assignments appear reasonable.	

X				EST 5	Major Folder quantity units and unit proces appear reasonable.	
X				EST 6	Major folders developed to support a coherent construction schedule development.	
X				EST 7	Major construction features supported by quantity take-offs and appear reasonable.	
					CONSTRUCTION ESTIMATE DETAILS	
				MISC	**Miscellaneous Estimate Details**	**REVIEW COMMENTS**
X				MISC 1	Estimate covers the many minor cost items, that together, can add significantly to the project.	
			X	MISC 2	Costs include any potential Hazardous, Toxic, and Radioactive Waste (HTRW) concerns.	
X				MISC 3	Limited use of generic Cost Book unit prices for critical cost items that could undermine the total cost accuracy.	
X				MISC 4	Limted use of Lump Sum, Each or Allowance items that do not accurately convey scope or pricing.	
X				MISC 5	Limited use of over-ridden unit or detailed costs that results in lost confidence and greater risks.	
				LAB	**Labor**	**REVIEW COMMENTS**
X				LAB 1	Current labor rates used that match the estimate date and location where the work is occurring.	
X				LAB 2	Actual labor rates determined to be reasonable, considering the type of work and other site factors.	
X				LAB 3	Overtime application appears justified, reasonable and logical for major work items.	
X				LAB 4	If overtime is used, the direct cost markup factors correctly entered and applied.	
X				LAB 5	Application of Payroll Tax and Insurance (PT&I) for the selected Contractors: State Unemployment Insurance (SUI) based on the state in which the work is occurring vs. using the AVG default.	
X				LAB 6	Under PT&I for Workmen's Compensation Insurance (WCI), was the selected Contractor Class based on the actual work to be performed vs. using the default for Concrete Work?	
X				LAB 7	Labor rates take into consideration potential labor shortages and includes any necessary subsistence or per diem for critical labor elements.	
X				LAB 8	Labor consideration made in mobilization and demobilization efforts.	
X				LAB 9	Correct labor rates used for Building, Heavy, Highway, Residential.	
			X	LAB 10	Marine Work – Work performed on or over navigable waterways addresses Longshoreman and Harbor Workers Act insurance, if required by the state.	No additional LS&H factor added. Estimate assumes large landbased rock/earth contractor.
			X	LAB 11	Dredging – Labor rate database updated to reflect the latest wage rates available for dredging work at the location.	Historical unit cost for dredging utilized in estimate.
			X	LAB 12	Dredging – Labor rates appear reasonable, based on the location and type of plant performing the work.	Historical unit cost for dredging utilized in estimate.

Estimate

				EQ	Equipment	REVIEW COMMENTS
X				EQ 1	Correct regional equipment rates used for the location where the work is occurring.	
X				EQ 2	Database updated to reflect the latest fuel prices for the work site.	
X				EQ 3	Critical equipment choices, size and rates appear reasonable, considering work type and site conditions.	
X				EQ 4	Rates for Average, Difficult, Severe or Standby are correctly applied and justified within the notes.	
X				EQ 5	Standby rates used, in order to ensure that Ownership Costs for equipment were covered for the normal 40 hour work week.	
X				EQ 6	Standby rates included for equipment mobilization and demobilization.	
X				EQ 7	Rental rates used for equipment not normally owned by the selected contractor. Were operating costs for rented equipment included?	
X				EQ 8	If warranted, were other factors (such as the Cost of Money) updated to reflect current conditions?	
			X	EQ 9	Dredging – Based on the actual site conditions, quantities, disposal areas, and schedule: was the selected dredge plant determined to be appropriate for the contract at hand?	
			X	EQ 10	Dredging - Appropriate dredge, dredge size and number of dredges reasonable for the work.	
			X	EQ 11	Dredging – Dredge plant costs based on the current CEDEP database.	
			X	EQ 12	Dredging - Was the dredge plant database, contained in CEDEP, reviewed and were plant costs determined to be reasonable based on the proposed work?	
			X	EQ 13	Dredging – Include costs for dredge plant during periods of standby or non-working hours and weather impacts.	
				CP	**Crews & Productivity**	**REVIEW COMMENTS**
X				CP 1	Critical crew composition and productivity appear reasonable for the major work items.	
X				CP 2	Productivity efficiencies or inefficiencies considered and explained.	
X				CP 3	Critical project productivity rates appear reasonable. Notes describe logic.	
X				CP 4	Heavy equipment crews include the supporting labor and equipment necessary to perform the task at the selected productivity.	
X				CP 5	For large earthwork projects, crew assemblies and productivities for excavation, load, haul, placement, compaction and disposal correlate.	
			X	CP 6	Dredging – crew productivity and any applied efficiency factors adequately justified in the estimate.	
				MAT	**Materials**	**REVIEW COMMENTS**
X				MAT 1	Major quantities supported by a quantity take-off document.	Rock quantities provided by EC-HY
X				MAT 2	Major, critical or volatile materials and quantities identified at the detail level.	
X				MAT 3	Estimate correctly includes State Sales Tax or Gross Receipts Tax to materials and supplies purchased for the contract.	

X				**MAT 4**	Estimate notes identify the source of major material quotes, with source, name and date of quote (escalation concern).	
X				**MAT 5**	Estimate makes adjustments for loss due to handling, placement, cutting, transportation, contamination, etc. Notes document adjustments.	10% Added to rock quantities.
X				**MAT 6**	Earthwork quantities indentified based on BCY for excavated material, LCY for hauled material, ECY for placed material.	
X				**MAT 7**	Earthwork quantities make reasonable adjustments between BCY, LCY and ECY.	
X				**MAT 8**	Line item note description for material purchase indicates if shipping is included for major items.	
				MOB	**Mobilization - Preparatory Work, Demobilization – Cleanup**	**REVIEW COMMENTS**
X				**MOB 1**	Mobilization and demobilization costs are detailed or appropriate.	
X				**MOB 2**	Total mobilization and demobilization cost appear reasonable.	
X				**MOB 3**	Multiple mobilizations considered for longer projects impacted by weather or environmental restrictions.	
			X	**MOB 4**	Dredge work: Estimate includes preparation of dredge attendant plant for transfer, the cost to move all plant and equipment return of tug or towing vessel, and preparation of the plant to start work.	
			X	**MOB 5**	Dredge Work: Project and estimate clearly include a construction support site.	
			X	**MOB 6**	Dredge Work: Estimate includes all costs to secure machinery and equipment for storage.	
			X	**MOB 7**	Dredging - Pipeline mobilization, assembly and relocation for surface and underwater appropriately considered.	
				SUB	**Subcontracting**	**REVIEW COMMENTS**
			X	**SUB 1**	Subcontractor assignments and markups reasonable for the tasks assigned.	Estimate assumes single prime contractor with no subs. Rock delivery sub included with material purchase price of rock.
			X	**SUB 2**	Estimate identifies subcontract quotes and addresses markup applications with the quotes.	
			X	**SUB 3**	Appropriate consideration has been made in addressing multi-tier subcontracting for specialty items.	
				PR	**Prime Contractor**	**REVIEW COMMENTS**
x				**PR 1**	Prime contractor(s) has been aptly assigned with reasonable markups.	
X				**PR 2**	Are appropriate taxes included or excluded as may be required?	
X				**PR 3**	Field office overhead reasonable for this project?	
X				**PR 4**	Field Office Overhead includes mobilization if not identified elsewhere.	
X				**PR 5**	Home office overhead appears reasonable for the type of prime contractor specialty.	
X				**PR 6**	Profit appears reasonable and based on the weighted guideline method or justified by other means.	
X				**PR 7**	Bond appears reasonable.	

Schedule

Project Title & Location:					MCR Major Rehab	REVIEW COMMENTS
Project Review Phase:					Feasibility Report	
Product Date:					24-Apr-12	
Reviewer Name & Phone:					Rick Russell, (503)808-4791	
Review Date:					RUSSELL.RICKY.L.1231401349 E-Signed by RUSSELL.RICKY.L.1231401349 VERIFY authenticity with ApproveIt	
Y	**N**	**N/P**	**N/A**			
				SCH	**SCHEDULES**	
				CS	**Construction Schedule**	**REVIEW COMMENTS**
X				**CS 1**	Reflects the estimate and identifies critical aspects of the project scope and construction activities.	
X				**CS 2**	Key milestones are depicted.	
X				**CS 3**	Reflects reasonable logic of activities performed.	
X				**CS 4**	Indicates a likely critical path.	
X				**CS 5**	Reflects the estimate productivities for critical path items.	
X				**CS 6**	Presents sequential and parallel activities where reasonable.	
X				**CS 7**	Makes distinction between single shift, and double shift.	
X				**CS 8**	Takes into consideration overtime where applicable.	
X				**CS 9**	Depicts critical or time-sensitive orders or procurements.	
X				**CS 10**	Considers weather issues, environmental restrictions, winter construction.	
X				**CS 11**	Considers project ramp up, mobilization and demobilization.	
				PS	**Project Schedule**	**REVIEW COMMENTS**
X				**PS 1**	The Project Schedule in the decision document report includes all FEATURE activities; i.e. review and approval, planning, engineering and design, procurement, construction, close-out and turn-over.	
X				**PS 2**	The project schedule clearly presents reasonable dates to determine inflation based on escalation indexes, i.e., the activity beginning date or the activity midpoint?	

CSRA-Contingency

Project Title & Location:					MCR Major Rehab	REVIEW COMMENTS
Project Review Phase:					Feasibility Report	
Product Date:					24-Apr-12	
Reviewer Name & Phone:					Rick Russell, (503)808-4791	
Review Date:					RUSSELL.RICKY.L.1231401349 E-Signed by RUSSELL.RICKY.L.1231401349 VERIFY authenticity with ApproveIt	
Y	**N**	**N/P**	**N/A**			
					RISK-BASED CONTINGENCY	
				CSRA	**Formal Cost and Schedule Risk Analysis (CSRA for >$40M)**	**REVIEW COMMENTS**
X				**CSRA 1**	CSRA structure and process follows the Cost Dx guidance.	
X				**CSRA 2**	CSRA model provided in electronic format using Excel and Crystal Ball softwares.	
X				**CSRA 3**	CSRA Report follows Cost Dx template.	
X				**CSRA 4**	CSRA considers total cost and total schedule, all features.	
X				**CSRA 5**	Risk Register developed by major PDT members for all project Features.	
X				**CSRA 6**	Organizational and PM risks considered.	
X				**CSRA 7**	Contract Acquisition risks considered.	
X				**CSRA 8**	Technical risks considered.	
X				**CSRA 9**	Scope quality and detail addressed.	CSRA Update to 4/24/2012 data
X				**CSRA 10**	Lands and Damages and Relocations considered.	
X				**CSRA 11**	Regualtory and Environmental risks considered.	
X				**CSRA 12**	Construction risks considered.	
X				**CSRA 13**	Estimate and schedule accuracy risks considered.	
X				**CSRA 14**	Volatile pricing and extreme escalation considered.	
X				**CSRA 15**	Material availability and transport considered.	
X				**CSRA 16**	External risks: funding, stakeholders, labor, weather, opposition, bidding competition considered.	
X				**CSRA 17**	Does the CSRA consider opportunities such as VE and alternatives?	
X				**CSRA 18**	Risk register tracks logically from Concerns, PDT Discussions, Likelihood and Impacts to a reflective Risk Level.	

X				**CSRA 19**	Risk model considers any risk duplications and correlations between cost and schedule risk events?	
X				**CSRA 20**	Risk event correlations have been minimized.	
X				**CSRA 21**	CSRA model includes the moderate and high risks.	
X				**CSRA 22**	CSRA considers both internal and external risks.	
X				**CSRA 23**	CSRA supported by market research and documented assumptions.	
X				**CSRA 24**	CSRA results traceable back to the PDT Risk Events.	
X				**CSRA 25**	CSRA model variance distributions appear reasonable w/ backup assumptions.	
X				**CSRA 26**	Contingency value based upon an 80% confidence level.	
X				**CSRA 27**	Contingencies appear reasonable based on project complexity and ATR findings.	
				CV	**Contingency Value**	**REVIEW COMMENTS**
X				**CV 1**	Rates appear reasonable for each major Feature item?	
X				**CV 2**	Overall rate appears reasonable based on reviewers knowledge of project scope and estimates.	

TPCS

Project Title & Location:					MCR Major Rehab	REVIEW COMMENTS
Project Review Phase:					Feasibility Report	
Product Date:					24-Apr-12	
Reviewer Name & Phone:					Rick Russell, (503)808-4791	
Review Date:					RUSSELL.RICKY.L.1231401349	
Y	**N**	**N/P**	**N/A**			
				TPCS	**TOTAL PROJECT COST SUMMARY in Current Dollars (first**	
X				**TPCS 1**	Proper TPCS format (ETL 1110-2-573).	
X				**TPCS 2**	Price level date shown is consistent with the estimate preparation date.	
X				**TPCS 3**	All project-related Civil Works WBS Features depicted.	
X				**TPCS 4**	Base costs reflects the esitmate development in current dollars.	
X				**TPCS 5**	Summary page roll up supported by sub-project calculations.	
X				**TPCS 6**	Costs reasonable for PED (30 Feature). Note: percentages are sometimes used to develop these costs.	
X				**TPCS 7**	30 Feature clearly includes costs for PM, P&E, E&D, Reviews & VE, Contracting, reprographics, EDC, Planning during construction.	
X				**TPCS 8**	Costs reasonable for Construction Management (31 Feature Code). Note: percentages are sometimes used to develop these costs.	
X				**TPCS 9**	Contingencies shown separately for each Feature.	
X				**TPCS 10**	Contingency rates match the risk based contingency results (commonly the 80 percent confidence level).	
					TOTAL PROJECT COST SUMMARY in Current Dollars (second column set)	
X				**TPCS 11**	Depicts budget year for decision document funding request.	
X				**TPCS 12**	Includes escalation from estimate date to budget year: EM 1110-2-1304, Civil Works Construction Cost Index System (CWCCIS).	
X				**TPCS 13**	Captures total project cost for all Featrures to budget year.	
					TOTAL PROJECT COST Inflated to Fully Funded Estimate (third column set)	
X				**TPCS 14**	Escalation dates and rates shown for each inflated Feature.	
X				**TPCS 15**	Escalation dates consistent with the project schedule.	
X				**TPCS 16**	Escalation based on price indexes from the current CWCCIS, EM 1110-2-1304 and correctly applied.	

			X	**TPCS 17**	Section 902 Limit ONLY; If lands and damages are inflated, is the escalation for inflation based on the Consumer Price Index? (ref. ER 1105-2-100, Determining Section 902 Limit)	
					TOTAL PROJECT COST SUMMARY - Federal and Non-Federal Costs	
X				**TPCS 18**	Federal and non-Federal cost share percentages shown.	
			X	**TPCS 19**	Project cost share percent consistent with the Cost Sharing Agreement?	
			X	**TPCS 20**	If applicable, is the cost/value of non-Federal in-kind services shown?	
			X	**TPCS 21**	Cost shares calculated correctly.	
X				**TPCS 22**	Signature blocks for PM, Cost Chief, Real Estate Chief (ER 1110-2-1302)

Y	**N**	**N/P**	**N/A**			
					REPORTS - Basic Information for Reviewer – Scope and Form	
				MR	**Draft Main Report, General**	**REVIEW COMMENTS**
X				**MR 1**	Complete report document provided. As a minimum: Main Report, Engineering Appendix, Cost Appendix, cost tables and project schedule.	
X				**MR 2**	Package meets the requirements within ER 1105-2-100, Exhibit G of the Planning Guidance Notebook?	
X				**MR 3**	Executive Summary clearly presents the "Total Project Cost" (TPC) inflated through the project schedule. The TPC at the time the project is authorized by Congress becomes the Baseline Cost Estimate (BCE). The BCE is subject to cost limits of Section 902 Water Resources Development Act of	
X				**MR 4**	Reported costs for all project Features included in the TPC and reflect the estimating products.	
X				**MR 5**	Report indicates the Total Project Schedule or duration (ER 1110-2-1150).	
	X			**MR 6**	Both required costs (budget constant dollars and fully funded) presented in the Executive Summary.	
	X			**MR 7**	Report makes distinction between the Federal and Non-Federal dollars.	
					Comparative Construction Cost Estimates	**REVIEW COMMENTS**
X				**MR 8**	Presents the various estimate scopes, technical/design data, method of construction, and assumptions used for developing the comparative estimates included and described (ER 1110-2-1302).	
X				**MR 9**	Comparative cost estimates developed at the same price level.	
X				**MR 10**	TPC of each comparative estimate accurately used in the economic analysis comparisons, such as costs and benefits at the same price level (ER 1105-2-100).	
X				**MR 11**	Contingencies adequate for each alternative in consideration for the alternative risks/complexity.	
					Cost Engineering Appendix	**REVIEW COMMENTS**

Reports

X				**CA 1**	Summarizes the scope of the supporting documents and describes the basis of the estimate, such as method of construction, major assumptions and cost data resources used to cost the major cost elements (ER 1110-2-1302).	
X				**CA 2**	Summarizes the uncertainties associated with major cost items (ER 1105-2-100, appendix E).	
X				**CA 3**	Summarizes the cost risk and resulting contingency development for the recommended plan construction cost estimate. A risk analysis report is required for any project estimated to greater than $40M.	
X				**CA 4**	Describes the development of the Plan construction schedule.	
X				**CA 5**	Summarizes and describes the basis and development of TPC. For example, the source and basis of engineering and design (E&D) (Feature 30), construction management (Feature 31), other pertinent feature costs, the price level of the constant dollar estimates (preparation date and program year date), and basis of cost indexes for inflating the project costs (inflated dollar basis) through the project schedule.	

MCR Jetties Major Rehab Report

Project Management Plan

Prepared by: Project Delivery Team
Portland District
US Army Corps of Engineers
P2 Project Number: 123160
Original Date: May 2006 Revision Number: 02 Revision Date: June 2012

TABLE OF CONTENTS

APPENDICES

1. PURPOSE OF PLAN

The purpose of this Project Management Plan is to establish scope, schedule, budgets, and technical performance requirements for the management and control of the project from planning, engineering, and design through construction. This plan has been developed in accordance with Portland District Project Management Business Process Policy and Procedure Manual and Engineering Regulation 5-1-11.

2. PROJECT AUTHORIZATION

Congress authorized improvement of the Mouth of the Columbia River (MCR) for navigation through the following legislation:

- Senate Executive Document 13, 47th Congress 2nd Session (5 July 1884) authorized the Corps to construct the south jetty (first 4.5 miles) for the purpose of attaining a 30-foot channel across the bar at the MCR.
- House Document 94, 56th Congress 1st Session (3 March 1905) authorized the Corps to extend the south jetty (to 6.62 miles) and construct a north jetty (2.35 miles long) for the purpose of attaining a 40-foot channel (0.5 mile wide) across the bar at the MCR.
- House Document 249, 83rd Congress 2nd Session (3 September 1954) authorized a bar channel of 48 ft depth and a spur jetty ("B") on the north shore of the inlet. Funds for Jetty "B" construction were not appropriated.
- Public Law 98-63 (30 July 1983) authorized the deepening of the northern most 2,000 ft of the MCR channel to a depth of 55 ft below MLLW.

3. PROJECT BACKGROUND AND HISTORY

The South Jetty and North Jetty at the mouth of the Columbia River (MCR) were constructed to secure the Federal navigation channel. The South Jetty is about 6.6 miles long. Its first 4.3 miles were constructed between 1885 and 1895 and was raised and extended to its authorized length in 1913-1914. In addition to the primary South Jetty, four groins perpendicular to the jetty (lengths 500 to 1000 ft.) were also authorized and constructed in order to stabilize the jetty foundation. The length of South Jetty being addressed in this study extends from approximately station 145+00 to station 375+50, a length of approximately 4.4 miles.

The North Jetty is about 2.3 miles long and was constructed between 1915 and 1917. Jetty A was constructed to a length of 1.1 miles and is located upstream of the North Jetty in order to train the navigation channel away from the North Jetty foundation. A second training jetty of a similar length as Jetty A, Jetty B, was also authorized but never constructed. Its location was proposed to be between Jetty A and the North Jetty. These existing project features were authorized by the River and Harbor Acts of 5 July 1884, 3 March 1905, and 3 September 1954.

4. PROJECT PURPOSE

All three primary jetties at the MCR, the North Jetty, South Jetty, and Jetty A are in need of repair including major rehabilitation of seriously deteriorated sections which have been exposed to increased wave heights and deteriorated foundation conditions. The last major repairs on the three structures were, 1965, 1982, and 1962 for the North, South, and Jetty A, respectively. Interim repairs (design based on a 10% annual wave exceedence) were conducted on a portion of the North Jetty during 2005. Interim repairs are scheduled for portions of the South Jetty for 2006 and 2007.

Structural degradation has accelerated in recent years because of increased storm activity and loss of sand shoal material, upon which the jetties were constructed, resulting in increased jetty maintenance costs and emergency repairs. Damages to Jetty A may result in a reduced ability to train the navigation channel flow away from the North Jetty foundation. Breaching of either the North or South Jetties would allow sand to migrate into the Columbia River navigation channel, thereby potentially disrupting deep draft navigation and increasing dredging requirements. Scour of the seabed along the channel-side of the North Jetty has resulted in increased depths of 10 to 40 ft, impacting not only the stability of jetty foundation but also wave impact on the already vulnerable jetty cross section. Increased depths along both the ocean-side and channel-side of the South Jetty have also resulted in increased wave impact. The North, South, and Jetty A heads have been damaged for a length of 2040 ft., 6210 ft., and 890 ft., respectively.

5. PROJECT SCOPE

The Major Rehabilitation Project Evaluation Report (Major Rehab Report) will address all three primary jetties, north, south, and Jetty A. The main purpose of the rehabilitation is to provide a reliable and cost-effective repair for the north and south jetties which control the navigation channel and to Jetty A, which protects the north jetty from foundation scour. Jetty roots and trunks will be the focus of the first part of the Major Rehab Report, scheduled for completion in March 2007. Since foundation stability is essential to obtaining a reliable long-term repair, jetty-perpendicular spur groins will also be evaluated. The first report will evaluate methods to stop further recession of the jetty heads by stabilizing the existing head position. The next part of the Major Rehab Report will address the necessity and extent of repairing the deteriorated heads of the 3 jetties.

The intent of the proposed design concepts will be three-fold: (1) Improve the stability of the foundation (toe) of each jetty as affected by scour; (2) Improve the side slope (above and below water) stability of each jetty as affected by classical static slope stability criteria; and (3) Improve the dynamic stability of each jetty as affected by wave forces impinging on the jetties.

The proposed rehabilitation work would occur along a 23,100 ft reach of the south jetty (stations 145 to 375+50) and a 12,200 ft reach of the north jetty (stations 0 to 122). Jetty A stations addressed would be from station 40 to 97, a length of 5,700 ft. The first phase of the rehabilitation work would require placement of approximately 200,000 to 800,000 tons along the north jetty and 500,000 to 1,200,000 tons along the south jetty. Stone placement along Jetty A would be expected to range from 80,000 to 200,000 tons. The total stone placed on the south and north jetty to date is 8.7 and 3.3 million tons, respectively. Armor stone sizes for the proposed rehabilitation is expected to range from 15 to 50 tons for the north and south jetties and from 10 to 30 tons for the Jetty A.

5.1 General

- The Major Rehab Report will center around the structural integrity of the jetties including the North Jetty, South Jetty and Jetty A

- The Project phases will include: A Major Rehab Report concentrating on the roots, trunks of the North and South Jetties and restoring the jetties in a general sense within the authorized limits. Rehabilitation of Jetty A will also be studied during this phase. After the Major Rehab Report, a Design Documentation Report (DDR) and plans and specifications (P&S) will be prepared, followed by construction for each of the two major rehab reports.
- The objective of the Major Rehab Report is to determine the proper level of Federal investment to extend jetty structure life to secure the Federal navigation channel.
- Identification of and stakeholders to date include: Users of the river system as well as the park system. We will be focusing our public outreach to the Columbia Solutions Group, a group supported and endorsed under a signed MOU by CEQ and both Governors for Oregon and Washington. In addition, the Lower Columbia Ports and the Columbia River Channel Coalition will be actively involved. The study will also involve a public process and at least one set of public meetings.
- Services to be Provided: Engineering , environmental, and economic input and analysis to produce the key products listed below.
- Key Products will consist of the Major Rehab Report, DDR, and P&S.
- Location: The Project is located at the Mouth of the Columbia River, Oregon and Washington.
- This work is intra-related to the O&M of the MCR project, Regional Sediment Management work at the MCR, and the MCR jetty interim repairs to both the North and South Jetties.

5.2 Critical Assumptions and Constraints

This study focuses on the structural stability of the jetty structures and assumes that the ebb tidal shoal will continue to erode at the current rate and trend.

5.3 Product Plans

The Major Rehab Report will consist of the following details:

5.3.1 Environmental Compliance

Development of the Environmental Assessment (EA) shall be consistent with protecting the Nation’s environment, pursuant to national environmental statues, applicable executive orders, and other Federal requirements. The EA shall address all requirements of all applicable environmental statutes for all alternatives considered, including the requirements of the National Environmental Policy Act, Section 404 of the Clean Water Act, Section 103 of the Marine Protection, Research, and Sanctuaries Act, the Coastal Zone Management Act, and the Endangered Species Act.

5.3.1.1 NEPA Compliance

The National Environmental Policy Act (NEPA) of 1969, as amended (NEPA) (42 U.S.C. 4321 et seq.) and the Council on Environmental Quality (CEQ) NEPA regulations (40 CFR Parts 1500-1508) contain provisions that require Federal agencies to consider and evaluate the environmental impacts and prepare Federal rationale that documents proposed Federal actions in accordance with the letter and spirit of the Act. The NEPA process will be used to ensure that all project activities and products are in full compliance with applicable environmental laws and regulations. In addition, the EA and integrated NEPA document will be subjected to public review, and will incorporate comments from State, Federal, and local agencies, Native American Tribes and non-governmental agencies.

Corps guidance for implementing the NEPA process can be found in ER 200-2-2, *Procedures for Implementing NEPA*. The various components of the project will be analyzed for impact on the environment. In addition, NEPA compliance will be fully integrated with the six step planning process.

5.3.1.2 Clean Water Act Compliance

Section 404 of the Clean Water Act of 1977 requires that all projects involving the discharge of dredged or fill material into waters of the United States be evaluated for water quality and other effects prior to making discharge. In-water discharges included in the base plan will be evaluated in accordance with guidelines established by the EPA under the authority of Section 404(b)(1) of the Act. A Section 404(b)(1) evaluation of the impacts on water quality will be included in the application for the 401 certification.

5.3.1.3 Endangered Species Act Compliance

The Endangered Species Act is intended to protect and promote the recovery of animals and plants that are in danger of becoming extinct due to the activities of people. A list of threatened or endangered species likely to occur in the vicinity of the project will be obtained from the U.S. Fish and Wildlife Service and NOAA Fisheries Service. Biological assessments will be prepared that examine the impacts associated with implementing the project. This work will require close coordination and cooperation with various oversight agencies, in particular, the ODEQ, NOAA Fisheries Service, ODFW, and USFWS. The USFWS and NOAA Fisheries Service will review the Biological Assessments and prepare Biological Opinions that assess the project's compliance with the ESA. The Biolgical Opinions may also contain terms and conditions required to implement the project. USACE will prepare an implementation plan to comply with any terms and conditions contained in the Biological Opinions.

An Essential Fish Habitat (EFH) assessment will also be prepared as required under the Magnuson Fishery Conservation and Management Act. The EFH assessment will be prepared concurrently with the Biological Assessments. The U.S. Fish and Wildlife Service and NOAA Fisheries will review the EFH assessment concurrent with the Biological Assessments. A response to the EFH will be prepared and it may contain also terms and conditions required to implement the project. USACE will then prepare an implementation plan to comply with the terms and conditions.

5.3.1.4 Cultural Resources

Cultural resource studies are required by Federal and state law to determine potential impacts on historic and prehistoric archaeological resources as a result of project related activities. All proposed project areas will be examined for cultural resources potential. This will include file searches of existing site information, field surveys as needed, and coordination with the Oregon State Historic Preservation Office, Advisory Council, and Native American Groups. A report of findings and recommendations will be prepared and submitted to the state SHPO.

5.3.2 Plan Formulation/Economics/Main Report

Development of the Major Rehab Report will follow the USACE planning process. The USACE planning process consists of six steps as defined in Section 2-3 of ER 1105-2-100. The six steps consist of 1) identify problems and opportunities, 2) inventory and forecast conditions, 3) formulate alternative plans, 4) evaluate alternative plans, 5) compare alternative plans, and 6) select a plan. This process provides a systematic approach to making determinations at each step so that the interested public and decision-makers are fully aware of the basic assumptions employed, the data and information analyzed, the areas of risk and uncertainty, the reasons and rationales used, and the significant implications of each alternative plan. All steps in the planning process shall be thoroughly documented. The final planning products shall consist of a draft and final Major Rehab Report with NEPA documentation.

5.3.3 Engineering Appendix

The engineering appendix will conform with Major Rehabilitation technical guidance. Reliability indices will be calculated for existing conditions as well as for the full range of alternatives for each structure. Alternatives developed will address potential alterations in jetty cross section as well as different material types and characteristics. The various designs as well as interpretation of potential impacts of design options will be supported by both physical and numerical hydraulic modeling. Physical consequences of alternative paths will be tied to economic consequences through the development of an event tree which utilizes a Monte Carlo simulation of risk throughout the project life.

5.3.4 Design Documentation Report

The purpose of the DDR is to document the final design concept for the construction of the MCR North and South Jetties. The DDR provides the technical basis for the plans and specifications. All technical, construction, environmental, and operating issues regarding the MCR North and South Jetties will be resolved during the DDR phase prior to the beginning of plans and specifications. The DDR will also serve to document basic design criteria, design decisions, design assumptions, methods of analysis, and summarize important calculation results. Each technical specialty will include a chapter in the DDR. Construction cost estimates and schedules for the construction of the MCR North and South Jetties will be developed. The work will be done using in-house technical staff. Purchased professional services will be used as necessary to support the in-house effort.

This project requires extensive modification of an English units based structure. Therefore metric units will not be used on this project.

Major tasks to be accomplished are listed below:

- 3-Dimensional Hydraulic Model
- Quarry Investigations
- VE Study
- Following construction design decisions made during EDC and construction will be documented and included as a final section, ER 110-2-1150.

5.3.5 Plans and Specifications

Contract drawings and specifications will be prepared for the construction of the MCR North and South Jetties. A formal, approved construction cost estimate will be prepared that will serve as the Independent Government Estimate. The PDT will also prepare an Engineering Considerations and Instructions (ECI) report outlining the engineering considerations, design concepts, design assumptions, special instructions, and any unique design details that went into the development of the construction contract. The purpose of this report is to aid field personnel in the supervision and inspection of the construction contract. The work will be done using in-house technical staff. Purchased professional services will be used as necessary to support the in-house effort.

This project requires extensive modification of an English units based structure. Therefore metric units will not be used on this project.

6. PROJECT DELIVERY TEAM

The Project Delivery Team (PDT) includes: the Project Manager, District technical staff, stakeholders, and division staff members necessary to effectively develop and deliver the project. The Project Manager is responsible for overall project execution and is the team leader of the project delivery team. In addition, the Project Manager is the District point of contact and operates as the District Commander's representative for this project. Technical lead is responsible for the day-to-day management of their assigned product; compiling product budgets; development and updating of detailed product schedules; quality control of assigned products, assisting in the preparation of the PMP; and delivery of assigned products on schedule and within budget. There is one TL assigned for the MRR, as we move into the DDR and P&S Phase additional TL will be assigned for the those products and this PMP will be updated to reflect those decisions. PDT members contribute their particular expertise necessary for project execution. Team members for each WBS product, service, or deliverable are listed in Appendix A.

7. WORK BREAKDOWN STRUCTURE

The Work Breakdown Structure is a deliverable-oriented grouping of project elements that organizes and defines the total scope of the project. The Work Breakdown Structure identifies the products and sub-products that will be required to implement the total project. It presents these products and sub-products in a hierarchical arrangement. The Responsibility Assignment Matrix (RAM) lists the Work Breakdown Structure; identifies the organization responsible for accomplishing that work, and the technical lead for managing each product, deliverable, or service. The RAM is listed in Appendix B.

8. CONTRACTING AND ACQUISITION

Contract specific acquisition strategies will be developed for each individual contract to be advertised and awarded. Factors to be considered in determining the specific acquisition strategies include but are not limited to technical complexity of the work, whether a construction or a supply/install format will be used, environmental considerations/constraints, construction schedules and magnitude of construction. In addition, maximum consideration will be given to placing contracts with qualified small, small disadvantaged, and women-owned business concerns in support of the District's Small and Disadvantaged Business Utilization program. Acquisition strategies will be fully staffed through the Project Delivery Team and Office of Counsel.

9. COMMUNICATIONS PLAN

9.1 Project Delivery Team

Project delivery team members will generally meet bi-weekly (more or less often as necessary) to discuss technical issues, program strategy, critical milestones, budget, and team progress. Meeting minutes will be provided to the entire team and meeting minutes will be kept in the project directory.

9.2 Internal Briefings

The Project Manager will brief the District Corporate Board as required. The project's Technical Lead will brief the Engineer Review Board as required.

9.3 Regulatory and Resource Agencies

Meetings with the resource agencies will be done as necessary and will consist of brainstorming, criteria development and clarification, product review, and alternative evaluations and development. Agency input is critical during these meetings in regards to environmental clearances necessary for the project.

9.4 Public Involvement

The PDT is responsible for assisting the PM in determining all stakeholder project communications requirements, to include both external and internal communications. Mike McAleer has been selected for Public Affairs Office support, as a member of the PDT, for the development of the communications and public involvement plan based on the complexity and sensitivity of the project. A plan for public involvement is provided in Appendix E.

9.5 Project Directory

Electronic copies of all documents related to this project are stored in the project directory located at: contact project manager.

10. CHANGE CONTROL

10.1 Project Management Plan (PMP)

The Project Management Plan is a living document that will be updated or revised, as necessary, throughout the life of the project. Updates are defined as changes to the Project Management Plan that do not substantially modify the scope, schedule, or cost of the project. Updates to the PMP do not require formal review. Revisions to the PMP reflect changes in scope, schedule, or cost of the project and require formal review. Review with possible revisions to the Project Management Plan for this project are scheduled for:

- Prior to the Initiation of DDR
- Prior to the Initiation of P&S
- Prior to the Initiation of Major Rehab Report
-

10.2 Construction Change Orders

For construction contracts, NWP will utilize the Basic Change Order Document (BCD) used by the Resident Field Office (EC-R) for proposed construction contract modifications. Basic Change Order Documents from the Contracting Officer's Representative will be submitted ahead of time for approval and will be used by EC-R to alert the Project Manager of required revisions to the project estimate prior to the start of negotiations. The Project Manager will approve all discretionary changes, non-discretionary changes that exceed ACO authority, and confirm funding for all changes prior to finalization.

11. QUALITY MANAGEMENT

Quality control is the process employed to ensure the performance of a task meets the agreed upon requirements and appropriate laws, policies, and technical criteria, on schedule and within budget.

11.1 Project Management Plan

Quality control procedures, as applied to the Project Management Plan, will follow the Portland District Project Management Business Process Policy and Procedure Manual and Engineering Regulation 5-1-11.

11.2 WBS Products and Deliverables

The WBS products and deliverables will be produced for the following stakeholders: the public, NOAA Fisheries, Washington Department of Ecology, Oregon DEQ, and Oregon Department of Land Conservation and Development.

11.2.1 Quality Control

Product quality is the responsibility of everyone on the PDT. Technical quality of WBS products and deliverables shall be achieved through a process that includes development of realistic comprehensive work plans, well defined functional and technical criteria, close coordination among PDT members, and conformance to accepted USACE and industry standards, including ISO 9001 for engineering and construction products. In addition, WBS products and deliverables shall be reviewed by highly qualified staff from their respective section prior to submittal of the final product. For Engineering products and deliverables, computations will be checked and initialed prior to submittal of the final product.

11.2.2 Agency Technical Review

The purpose of an independent technical review is to assure the integrity and accuracy of the technical products produced. In particular, the ATRATR team will ensure that WBS products and deliverables are safe, functional, constructible, economical, and reasonable; engineering assumptions, concepts and analyses are valid and comply with accepted USACE and industry standards; economic analyses and cost estimates are reasonable and accurate; and that WBS products and deliverables comply with U.S. laws, regulations, and existing public policy. ATRATR certification is required for the following WBS products and deliverables:

- Major Rehab Report
- DDRs
- P&S

11.2.3 BCOE Certification

The purpose of Biddability, Constructibility, Operability, and Environmental Reviews (BCOE) is to ensure efficient construction that is environmentally sound, to minimize cost and time growth, to avoid unnecessary changes and claims, as well as to ensure safe efficient operations by the user. BCOE Certification is required for the following WBS products and deliverables:

- P&S
- DDRs

11.2.4 Reviews

WBS products and deliverables shall be reviewed as they are developed to ensure they meet project objectives, comply with regulatory and engineering guidance, and meet expectations of quality. Informal reviews, consisting of PDT presentations and discussions, shall be documented with meeting minutes. Formal reviews, consisting of review comments, review conferences, and backchecking, shall be documented using Dr. Checks. Product reviews will occur at the times shown in the schedule.

11.3 Construction Products

Obtaining quality construction is a combined responsibility of the construction contractor and the government. Construction products include those that are acquired using either Construction Contracts or Supply and Install Contracts. Quality control specifications will be incorporated into the contract specifications for each construction product. In general, the Contractor will implement a quality control system that ensures the final product is constructed in accordance with the contract plans and specifications and the project objectives. In addition, the Resident Office will develop a Quality Assurance plan for each construction product. Government Quality Assurance Representatives (GQAR) will monitor the construction progress and perform periodic on-site inspections as necessary.

11.4 Lessons Learned

As the project progresses, design lessons learned will be documented using the Design Quality Lessons Learned module in Dr. Checks and construction lessons learned will be documented in RMS. Lessons learned should focus on the positive aspects of a project as well as the negative ones.

12. SAFETY AND OCCUPATIONAL HEALTH PLAN

All aspects of this project shall comply with the Portland District Safety Plan. For construction or service contracts, contractors will submit an Accident Prevention and Site-Specific Safety Plan as identified in the contract specifications; in accordance with EM 385-1-1 (USACE Safety and Health Requirements Manual); and meeting Federal, state and local codes, regulations, and standards.

13. RISK MANAGEMENT PLAN

Risk management is the systematic process of identifying, assessing, making risk decisions, implementing controls, and analyzing risk decisions during the entire project life cycle. Monthly reviews by the project delivery team of progress and deliverables will assess potential problems and develop appropriate actions.

Risk will be minimized through the use of schedules, metrics, and assignment of specific responsibilities. Contingencies to manage financial risk have been incorporated in the cost estimates for each WBS product, deliverable, or service.

14. VALUE MANAGEMENT PLAN

Value Management (VM) is a process to facilitate and encourage the understanding, consideration, and integration of the needs of all stakeholders and PDT members. Value Management seeks the highest value for a project by balancing resources and quality. The VM process emphasizes the use of multi-disciplinary teams and their resulting synergy, using a functional analysis approach for decision making. The VM process will be applied continuously throughout the life cycle of the project.

Engineer Regulation 1110-2-1150 requires a value engineering study for all projects with an estimated construction cost of $2.0 million or more. The estimated construction costs exceeds $2.0 million, so a formal value engineering team study shall be performed on the earliest document available that establishes the functional requirements of the project and includes a Microcomputer Aided Cost Engineering System (MCACES) cost estimate. In addition, during the preparation of each design document, additional value engineering team studies will be conducted if the PDT identifies areas for potential cost savings and/or design improvements. It is envisioned that one VE study will be conducted after completion of the MRR and during the DDR.

To capture the benefits of potential cost reducing construction methods and technologies employed by a contractor, Value Engineering Change Proposal clauses, in accordance with FAR 52.248-3, will be included in all project construction specifications.

15. FISCAL MANAGEMENT

The Project Manager will allocate funds to the Technical Lead for completion of products as outlined in the PMP. The PM is responsible for management of all contingency. The Technical Lead is responsible for sub-allocations and detailed budgeting for their assigned products. The Technical Lead can change the distribution amoung team members without the approval of the Project Manager as long as the scope or overall cost of the product is not changed. It is anticipated that this will be done with concurrence from the affected offices. With the incorporation of the CEFMS financial system, the budget will be tracked and monitored at all times. Technical Lead will assist the Project Manager in the preparation of 2101's (i.e. monthly schedules of obligations and expenditures).

16. PROJECT CLOSEOUT PROCEDURES

Project Closeout will occur for construction efforts. After final inspection and acceptance of the project, property transfer documents will be prepared to transfer to plant in service. These documents include any as-built drawings, O&M manuals, warranties, or other documents pertaining to the project. This will occur as soon as practical following completion of construction of the project. Computations will be scanned and placed in the project directory. The Resident Engineer will process documents such as the final pay estimate and contractor evaluation required for closing the applicable construction contract. In addition, all construction documents and photos will be scanned and placed in the project directory after final close out of the construction contracts.

17. APPROVAL

FOR THE PROJECT DELIVERY TEAM:

____

Eric Bluhm
Project Manager

Appendix A – List Of Project Delivery Team Members

The team members listed below will be involved in all the WBS products, services, or deliverables mentioned in the PMP.

PDT MEMBERS		OFFICE	OFFICE SYMBOL	PHONE
Eric	Bluhm	Project Manager	CENWP-PM-FP	x4759
Mark	Brodesser	Technical Lead	EC-DC	x4914
Rod	Moritz	Coastal Engineer	CENWP-EC-HY	x4864

George Hart	ATR – Environmental	CENWS-PM-PL-ER
Kim Callan	ATR – Cost Engineering	CENWW-ED-C

APPENDIX B – RESPONSIBILITY ASSIGNMENT MATRIX

Work Breakdown Structure for Major Rehab Reports (Products, Deliverables, and Services).	**Action Office**	**POC**
Project Management	CENWP-PM-FP	Eric Bluhm
ESA/Environmental Compliances	CENWP-PM-E	Barbara Cisneros
Plan Formulation/Economics/Main Report	CENWP-HAC	Brian Shenk
Engineering Appendix	CENWP-EC-HY	Rod Moritz

Work Breakdown Structure for Future Phases (Products, Deliverables, and Services).	**Action Office**	**POC**
DDR	TBD	TBD
P&S	TBD	TBD

Appendix C – Project Schedule

The project schedule was developed using input from PDT members. Activities listed are those necessary to provide products, deliverables, and services listed in the Work Breakdown Structure (WBS). P2 Project Manager was used to link prerequisite tasks and the critical path method was used to determine major milestones in the overall project schedule. The P2 Project Number is 123160. Scheduled critical milestones and links among the tasks will be tracked and monitored. If milestones are missed, corrective actions will be discussed by the team and elevated to management as necessary if issues exist. The baseline schedule will be fixed after approval of the PMP.

Major project milestones are listed below. (S) or (F) indicates start or finish of an activity.

MAJOR PROJECT MILESTONES

Major Rehab Reports (Products, Deliverables, and Services)	**Baseline (F)**	**Actual**
PMP	July 2006	Revised
ESA/Environmental Compliances	Feb 2011	June 2012
Plan Formulation/Economics/Main Report	March 2011	June 2012
Engineering Appendix	March 2011	June 2012

Future Phases (Products, Deliverables, and Services)	**Baseline (F)**	**Actual**
DDR	Mar 2014	
P&S	Sep 2014	

Appendix D – Budgets and Cost Estimates

Project budgeting involves allocating the overall cost estimate to individual activities over time so that project cost performance can be measured. The funding source for this project is O&M.

Detailed cost estimates will be an appendix of the Major Rehab report and finalized during P&S.

Appendix E – Communications and Public Involvement

E.1 Purpose Statement: This plan provides direction and guidance for Portland District as it strives to provide its own employees, as well as special interest groups, local businesses, organizations and citizens with complete, accurate and timely information about the Mouth of the Columbia River North and South Jetties Major Rehabilitation Project Evaluation

E.2 Goals and E.3 Objectives:

- Ensure the Commander, project manager and technical leads are an active and integral part of the overall Mouth of the Columbia River North and South Jetties Major Rehabilitation Project Evaluation Communication Plan.
- Improve Corps communications to and with the media, special interest groups, businesses and citizens of the surrounding communities.
- Improve two-way communication within the Corps' own organization, especially within the Mouth of the Columbia River North and South Jetties Major Rehabilitation Project Evaluation PDT and the vertical team.
- Proactively provide information to all those impacted to give the Corps the opportunity to tell its story rather than rely on others to interpret the Corps' actions, issues and decisions during construction.
- Generate inclusiveness. Including everyone in the process builds teamwork and a feeling of belonging, breaking down feelings of us vs. them, which are common in relationships between the Corps and local citizens, especially when controversial issues arise.

E.4 Communications Team:

1. Background

Over the past six years the Portland District has been developing the MCR Jetties Major Rehabilitation Report (MRR). In June 2011, the foundation of the report—a planning tool called the "Stochastic Risk-Based Model"—was disapproved by HQUSACE. Consequently, the Portland District has spent the past year revising the model and MRR. Appendix H summarizes the key events—particularly over the past two years—and describes the differences between 2011 draft report and the final 2012 MRR.

2. History

The Corps began looking at applying a system approach to the MCR entrance in 1999, had an interruption from study to conduct interim repairs on the North Jetty in 2005, and the South Jetty in 2006 and 2007. The Portland District reinitiated the MRR effort in FY 2006 after facilitating emergency interim repairs on 3,000 feet the North Jetty in 2005; and later the placement of over 130,000 tons of stone to repair the South Jetty in 2006 and 2007. In early 2006 the district began discussion with Northwester Division (NWD) regarding the long-term maintenance of the jetties. Specifically, in February 2006, the district began scoping an accelerated study to address the extensive deterioration of the all three jetties of the MCR system: North, South and Jetty A, which protects the North Jetty root. It was determined that the study will need to clearly lay out what is authorized, what is rehabilitation, and what is new work. It was clarified that "jetty extensions" are not new work, rather rehabilitation of the current jetty arms. Lastly, it was agreed that modeling studies to support the recommended plan would be necessary.

In March of 2007 the district received delegated authority approval. This cleared the way for the MRR to be approved by NWD if the district met all policy requirements per EC 1165-2-206 (and today ER-1165-2-502). It was also determined that the MRR studies should be at a feasibility level of detail; however, some alternatives may be screened out a much lower level. For example, rebuilding the jetties to their authorized lengths were analyzed and determined infeasible, within and outside the existing jetty footprints.

From FY 07 through 10 the MRR planning model, the Stochastic Risk Based (SRB) model, was developed to assess and rank repair and rehabilitation alternatives. Concurrently, the Project Delivery Team (PDT) reached agreement on the base condition, the "fix-as-fails" approach, which assumed that the jetty would be maintained just in time to prevent a breach.

In addition, through FY10, NWP considered where the end of each of three jetties should be and developed three jetty length options:

- rebuild the jetties to their authorized lengths
- rebuild the jetties to the midpoint between the authorized length and the existing jetty end station
- rehabilitating the jetty to the current end station

NWP has considered major alternatives to the authorized cross-section that included designs that stayed on the existing footprint and those that went off the existing footprint, including realigning the entire system. Alternatives that extended the jetty lengths significantly beyond the existing end station or reconstructed the jetties off the existing footprint were deemed infeasible.

In FY 2010, a 90% draft of the MRR underwent District Quality Control (DQC) and Agency Technical Review (ATR). The underlying tenets of that report included a base condition involving a fix-as-fails approach where each jetty was allowed to degrade as low as 20% of the originally authorized cross-section remaining above

MLLW -5, resulting in forecasted breaches. The hypothetical breaches would release material into the navigation channel, leading to emergency dredging. Breaches were forecasted to primarily occur in the winter, thus emergency dredging was very expensive, and reliability of the navigational channel became questionable. Moreover, breach volumes entering the navigation channel were difficult to quantify. In an attempt to model these effects, the SRB model code became more complex as the analysis was developed and the timing of the runs became very long and the economics was embedded within the model code. NWP also developed a qualitative numeric scoring of alternatives that included several factors beyond average annual cost.

The IEPR was conducted from December 2010 through April 2011. Concurrently, the SRB model underwent substantial review, including ATR approval and DDN-PCX model certification in January 2011. This documentation was then forwarded to HQUSACE for final approval where it was disapproved in June 2011 because the IEPR panel raised concerns about the frequency and severity of breaching and sediment transport in the base condition.

After consultation with NWD, it was decided that an MMR should be produced for the most critical portions of the North Jetty for inclusion in the FY 2014 budget submission. Therefore,
the lagoon fill between STA 20 to 60 and critical repairs between STA 86 to 99 were removed from the MRR alternatives and included in the revised base condition.

NWP then decided to revise the SRB model, MRR and appendices per IEPR comments and hired Moffatt & Nichol, a coastal engineering consultant. Furthermore, the A/E task order emphasized improving the model code; showing compliance with current technology and Corps policy; providing additional documentation; improving practicality with data inputs and outputs; and user manual; clearly identifying the use and limitations of the model consistent with EC 1105-2-412.

Due to the level of construction and high mobilization costs, the revised FY 12 base condition—identified as an interim-repair approach—was developed to replace the FY 11 “fix-as-fails” approach. The new base condition allows the upper portion of the jetty is allowed to be degraded until approximately 40% of the cross-section is remaining prior to repair action being initiated. This change in the base condition allows for repair actions to take place prior to a breach event, and thereby eliminates breaching and sediment transport through the jetty, affecting the navigational channel and significantly reduces winter emergency dredging.

The economics analysis is now outside the model in a post-process spreadsheet. The code has been modularized and simplified so that there is one code for all three jetties. The user’s manual provides enough detail for a knowledgeable coastal engineer to run the model. These changes improved the transparency of the model’s sub-routines, dependant and independent variables, and damage functions leading to the ultimate approval of the model on 27 April 2012.

The preceding series of events resulted in a change in the selected plans for the three jetties. Subsequent to the model review and IEPR, the MRR underwent DQC, NWD, and ATR reviews, including DDN-PCX review and approval of the report review plan and model review plan.

Sections 3, 4, 5, and 6 of this appendix outline key dates, multiple reviews, differences between the 2011 and 2012 MRRs, and document the study’s funding history. Eight attachments are included to document reviews.

3. Key Dates

a. FY 2006: Major Rehabilitation Report study initiated.
b. March 2006: NWD provides initial guidance
c. FY 07-10: SRB model developed and MRR study conducted.

d. 24 August 2010: ATR Certification Letter recommending model certification and approval for use to the Deep-Draft Navigation Center of Expertise (DDN-PCX), (see Attachment 1).
e. 21 October 2010: ATR of Major Rehab Report completed (all comments closed out, no certification memo on record)
f. 21 January 2011: DDN-PCX provides model certification and forwards documentation to HQUSACE for review (see Attachment 2).
g. 07 April 2011: Final IEPR comments, responses and backchecks provided by Battelle. Three of 25 comments remain open (see Attachment 3).
h. 09 June 2011: Draft SRB model disapproval memo provided by HQUSACE.
i. 15 August 2011: Disapproval memo signed (see Attachment 4).
j. 17 August 2011: Path forward memo requesting vertical team concurrence issued (see Attachment 5).
k. 26 August 2011: Task Order issued to Moffatt & Nichol to assist with SRB model revisions, validation and verification, and revisions to MRR and its appendices per the IEPR comments.
l. 01 December 2011: Model Approval Plan submitted to DDN-PCX (see Attachment 6).
m. 23 December 2011: Draft SRB Model User's Manual completed.
n. 06 January 2012: Draft Model User's Interface completed.
o. 13 January 2012: SRB Model Matlab code finalized.
p. 23 December 2011: Draft SRB Model User's Manual completed.
q. 06 January 2012: Draft Model User's Interface completed.
r. 13 January 2012: SRB Model Matlab code finalized.
s. 20 January 2012: IPR: NWP briefed HQUSACE, NWD model and MRR path forward.
t. 27 April 2012: HQUSACE approves the SRB model for one-time use.
u. 09 May 2012: Draft MRR provided to NWD for review and approval.
v. 29 May 2012: Revised MRR Review Plan resubmitted to the DDN-PCX.
w. 31 May 2012: NWD comments on MRR provided.
x. 04 June 2012: Revised MRR Review Plan approved by the DDN-PCX (see Attachment 7).
y. 07 June 2012: NWP responses to NWD comments provided.
z. 15 June 2012: Final NWP responses to NWD comments (see Attachment 8).
aa. 15 June 2012: Received Cost Certification from PCX at NWW
bb. 22 June 2012: Received ATR Certification on MRR (see Attachment 9).
cc. 29 June 2012:

4. Selected Plans Comparison

Key Component	2011 Report	2012 Report
North Jetty	Schedule Repair w/features (cap & spur groins) 11 alternatives evaluated Not NED Plan	Scheduled Repairs, hold head >11 alternatives evaluated NED Plan
South Jetty	Schedule Repair w/features (cap & spur groins) 14 alternatives evaluated Not NED Plan	Base Condition plan selected >14 alternatives evaluated NED Plan
Jetty A	Immediate Rehab w/features (cap & spur groins) 3 alternatives evaluated NED Plan	Scheduled Repairs, hold head >3 alternatives evaluated NED Plan
Model	NWP Lead	NWP/Moffatt & Nichol Lead
Cost	~$500M; 2012-2032 Contingency: 36% Mitigation (offloading, stockpile, wetland, 404)	$239M; 2015-2020 Contingency: 29% Mitigation (offloading, stockpile)
NEPA	2nd time for public review Signed FONSI (NJ lagoon fill, NJ critical repairs, SJ dune augmentation/stabilization)	2nd time for public review FONSI (MMR, MRR & SJ dune)

5. Differences between 2011 & 2012 Reports

Key Component	"Delta"	Comments
North Jetty	Base Condition (MMR actions: Lagoon Fill and critical repairs STA 86-99)	Base Condition not longer "fix-as-fails"; now interim repair
South Jetty	Less aggressive maintenance and repair	Change addresses IEPR comments
Jetty A	No head capping or spur groins	Hold head alternative evaluation will be reassessed during DDR
Model	User manual w/input interface; extensive external review by Moffatt & Nichol; modularity (3 sets of code down to 1 set); economics external to model; changed model parameters drove changes in alternatives and selected plans	HQUSACE approved model for one-time use on 27 April 2012
Cost	Construction Sequencing; shortened schedule	Used same assumptions, cost engineering tools and processes; NWW certification on both
NEPA	Included near-shore placement by Corps	

6. Funding History

Fiscal Year	Budget Amount	Appropriated Amount
2006	875,000.00	873,707.00
2007	475,000.00	467,009.00
2008	868,500.00	705,114.00
2009	387,000.00	560,260.00
2010	635,000.00	1,195,490.00
2011	750,000.00	762,000.00
2012	----	671,222.00
	$3,990,500.00	$5,234,802.00

CENAE-EP-HG 24 August 2010

MEMORANDUM FOR: Mr. Bernard E. Moseby, CESAM-PD-FE, Chief, Economic Analysis and Deputy Director, Deep Draft Navigation Planning Center of Expertise

SUBJECT: Review and Certification Letter for the Mouth of the Columbia River (MCR) Stochastic Reliability Based (SRB) Lifecycle Model for the MCR Major Rehabilitation Report

The following is the background information on the review process for the certification of the MCR SRB Lifecycle Model:

1. In October 2009, a request was made by the NWP PM to the ATR team leader to assist in obtaining model certification of the Mouth of the Columbia (MCR) Stochastic Reliability Based (SRB) model. This process was conducted using current USACE planning guidance and coordinated through the Deep Draft Navigation PCX to request from USACE Headquarters an "approved for use" status of the MCR SRB model.

2. A technical review of the MCR SRB model was initiated in November 2009 and has continued to date utilizing both part of the ATR team (Mr. Robert C. Patev, Team Leader and Mr. Wally Brassfield, ATR cost team member) and Mr. John Winkelman, a Coastal Regional Technical Specialist (RTS), from North Atlantic Division (NAD). Since the MCR SRB model was developed using the MATLAB language/software, Mr. Winkelman was an important part of this team due to his knowledge of the software, his technical position as a coastal engineer/planner Regional Technical Specialist with the HSDR PCX, and his past work experience in SPD on West Coast coastal navigation projects.

3. The review was begun in November 2009 by Mr. Patev and Mr. Winkelman and included a visit to CENAE by Mr. Hans Moritz, who is the developer of the MCR SRB model. The meeting lasted approximately two days and included a detailed presentation of the model code, model development assumptions, variable and model input descriptions, a discussion of the model output, and a lengthy discussion of model philosophy. Questions or comments generated prior to and during the meeting were documented and addressed as part of the Dr. Checks review process. Twenty three comments were generated and submitted into Dr. Checks in January 2010. Questions and comments were related to model coding, model variables and model constant value selection, model assumptions, and limited coastal engineering issues. Each issue and question was answered and/or addressed satisfactorily.

4. Following this meeting and installation of the MCR SRB MATLAB code at NAE, a number of variables and their ranges were defined to investigate model performance, sensitivity, and stability of the code. This was performed in terms of engineering reliability aspects of the program only. During this phase of the review, Mr. Moritz provided the review team with a list of key variables and constants within the code for validation. Many of these variables were discussed further during a number of

email/phone exchanges during this phase. After these communications and detailed examination of the code, the values selected in the model for engineering parameters were determined to be reasonable and based upon a sound engineering decision process. When these values were changed in the model, noticeable changes to the model output were recognized, but the model did not produce any unreasonable results in terms of engineering reliability.

5. The values for costs included in the MCR SRB model were reviewed and modified by Mr. Brassfield in July 2010. However, the validation of the methods and mathematical calculation for the estimation of the economic consequences produced by the model has not been reviewed by any team member since this was outside of their areas of expertise.

The following limitations, review assumptions and technical recommendations were drawn by the review team during their review:

1. With a model of this size and complexity it is difficult to determine if all of the code is error proof or if the model is providing the exact correct answer. However, based on the review, as described, the model, from a coastal analysis/performance stand point does appear to be reasonable and is a reasonable tool for determining the future, relative performance of various maintenance schemes for the MCR jetties discussed in the MRR. As with any model of this complexity, and for a system of this complexity, the precise numbers and resulting values are likely not absolutely correct but instead are reasonable and relatively correct between alternatives.

2. This model and code has only been reviewed as to what was included in the code installed at NAE in 2009. This review was limited only to the aspects of the engineering reliability and not the actual consequence determination in the program. The cost inputs have been reviewed by the ATR cost team member but the application of the economics to the outputs has not been validated as part of this review. In addition, any additional changes or modifications of the code should be reviewed by the ATR team to determine the validation of those modifications to the code and the replication of the results with previous versions of the code.

3. The MCR SRB model was developed to perform an integrated analysis of both engineering reliability and consequence assessment. Typically, major rehabilitation models are developed separately into stand alone models for engineering reliability and economic consequences. If the schedule permits, I would strongly recommend that the SRB process and results be validated with a simpler model using hazard functions from the SRB reliability curves and the development of consequences using a traditional economic simulation model.

4. During the Independent External Peer Review (IEPR), it is important to provide the additional documentation and explanations discussed in my previous comments. Also, the face to face meeting for explaining the model is essential due to the complexity of the model. This is a model that is trying to meet a difficult USACE planning objective that covers an immensely complicated coastal engineering project and forecasts an uncertain

future. It should also be made clear what the purpose of the model is, and that this is a project specific model that has been developed, honed, and calibrated for this specific project area. The numerous factors and variables, etc. within this model, to a great extent, are project specific and are not to be used in a generalized model for other USACE projects.

5. Based on the information presented above, I recommend that the MCR SRB lifecycle model be certified as is and a request be sent to USACE Headquarters as “approved for use” for the MCR Major Rehabilitation Report only.

If there are any questions regarding this memorandum, please do not hesitate to contact me at your earliest convenience.

MEMORANDUM FOR Commander, HQ USACE (CECW-NWD-RIT/Lisa Fleming)

SUBJECT: Model Certification – Approval for Use, Columbia River at the Mouth, Oregon and Washington, Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Stochastic Reliability-Based (SRB) Model

1. References:

a. EC 1165-2-209, "Civil Works Review Policy", 31 January 2010.

b. EC 1105-2-412, "Assuring Quality of Planning Models", 20 July 2009.

c. EC 1105-2-407, "Planning Models Improvement Program: Model Certification", 31 May 2005.

d. Memorandum, CECW-CP, 30 March 2007, Subject: Peer Review Process.

e. Supplemental information for the "Peer Review Process" Memo, dated March 2007.

2. In accordance with EC 1165-2-209, "Civil Works Review Policy" Model Certification – Approval for Use, the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Stochastic Reliability-Based (SRB) Model, has been coordinated with and executed through the Deep Draft Navigation Planning Center of Expertise (DNN-PCX).

3. The review was performed by Robert C. Patev, CENAE-EP-W (Team Leader) and John Winkelman, CENAE-EP-WM, New England District, Corps of Engineers. The Model Assessment Criteria documentation that supports a recommendation of 'Approval for Use' for the SRB is enclosed. The Deep Draft Center is requesting coordination of the enclosed documentation package through the Planning CoP Leader for processing, review and recommendation.

4. The Deep Draft Navigation Planning Center of Expertise (DDN-PCX) point of contact is Bernard Moseby, Technical PCX Deputy, CESAM-PD-FE, (251) 694-3884.

Compiled Comments and Responses

on the

IEPR of the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report

Comment (#1):

The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.

Basis for Comment:

Economics is the key consideration in evaluating the NED plan, which was selected as the recommended plan. Several issues were identified in the review documents and the economic spreadsheet models that could significantly change the outcome of the economic analysis and the selection of the recommended plan. These issues primarily pertain to the calculation of net present values (NPVs) and Average Annual Costs (AACs), and the presentation of the economic analysis results.

Calculation of NPVs and AACs

- The AACs, based on the NPVs presented in Table 2-1 and Table 2-2, appear to be based on a Federal discount rate of 4.125%, not 4.375%, as stated in the report.
- The calculation of the NPVs and AACs in the economic spreadsheet model for the North Jetty are based on a discount rate of 4.125%, not 4.375%, as stated in the report.
- The period (actual calendar years) of the annual stream of costs used to calculate the NPVs for each alternative differ between alternatives in the economic spreadsheet models; also, the actual calendar years included in these periods were not stated in the report.
- The unit costs for jetty repair and dredging, as presented in the SRB model, are increased over time such that after 50 years, costs will be 15% greater than at present. In accordance with ER 1105-2-100, p. 2-11 (USACE, 2000), when conducting economic analysis, prices should be held constant over the period of analysis.

Presentation of Results

- The NPVs and AACs in the spreadsheets for the North Jetty and South Jetty differ from the results presented in the report.
- The term NED, the process of calculating NED benefits, and the method of selecting the NED plan are not explained in Section 2 or Appendix C of the report.
- The SRB model uses Monte Carlo simulation to increase the confidence of life cycle estimates and allow for evaluation of variance by producing project cost output, including mean and standard deviation values (Appendix A2, p. A2-49). The risk and uncertainty associated with estimating the stream of annual costs and the resulting NPVs, AACs, and benefit-to-cost (B/C) ratios are not addressed in the economic analysis.
- The costs of the NED plan of $250 million in the Executive Summary are presented on a fully funded basis, whereas the costs in the main report are presented as NPVs, resulting in confusion.

Significance – High:

The inability to validate the economic analysis and the assumptions used in the economic spreadsheet model could impact the selection of the NED, or recommended plan.

Recommendations for Resolution:
1. Calculate the NPVs and AACs using the FY10 Federal discount rate of 4.375% for all alternatives; basing the NPVs on the stream of project costs for the 50-year period of analysis. 2. In accordance with ER 1105-2-100, Chapter 2 (USACE, 2000), revise the formulas in the economic spreadsheet models to reflect the same period of analysis for all alternatives. 3. State the years (annual stream of costs) used in calculating the NPV for each alternative and ensure consistency in alternative evaluation. 4. In accordance with ER 1105-2-100, Chapter 2, p. 2-11 (USACE, 2000), revise the repair and dredging costs to reflect the general level of prices prevailing during or immediately preceding the period of planning for the entire period of analysis. 5. Revise Section 2 and Appendix C of the report to include a definition of the term NED, an explanation of the process of calculating NED benefits, and the method of selecting the NED the plan. 6. In accordance with EP 1130-2-500, Appendix B, p. B-9 (USACE, 1996), report the results of all alternatives in a table displaying the mean net benefits and standard errors of each; providing the 90% confidence interval for the mean net benefits (mean+ 1.64x standard error). 7. Present the costs of the NED plan in the Executive Summary and the main report in both a fully funded basis and in NPV.
USACE Final Evaluator Response (#1)
CONCUR 1. **ADOPT NOW**. NPVs and AACs will be calculated using the current discount rate. Text in the report will be edited to match the discount rate used in the spreadsheets. NPVs will be based on the stream of costs for the 50-year period of analysis. 2. **ADOPT NOW**. The output from the SRB model used labels for the starting year of the analysis that were established years ago in the early stages of model development. While the labels appear to indicate that the initial years of the analysis are either 2008 or 2009, the actual first year of the analysis is generally considered to be in the future, rather than two or three years ago, and specifically would be the first year in which maintenance decisions could be impacted by the knowledge of a decision to perform major rehabilitation in the future. The output from the SRB model can be altered to show that the first year of model output is 2012, but the actual data for Year 1 of the analysis will not change. Labels in the Year column of each spreadsheet will be altered to show that the period of analysis always begins in 2012. In the event that the study continues on into 2012, the labels will be altered again to indicate that the period of analysis begins in 2013. **3.** **ADOPT NOW**. Each alternative will be evaluated using the fifty years from 2012 to 2061. **4.** **ADOPT in FUTURE .** The 15 % increasing trend of costs will be deleted from the base condition re-run. In addition one of the significant frequent repair alternatives will be re-run with the 15% increase taken out to assess with and without final NPV calculation impact. This should not affect the overall plan selection process. **5.** **ADOPT NOW.** Section 2 and Appendix C of the report will be revised to include a definition of the term NED, an explanation of the process of calculating NED benefits, and the method of selecting the NED the plan.

6. **ADOPT NOW.** The results of all alternatives will be displayed in a table showing the mean net benefits and standard errors of each; providing the 90% confidence interval for the mean net benefits (mean+ 1.64x standard error).
7. **ADOPT NOW.** The costs of the NED plan will be presented in the executive summary and elsewhere in the main report in both a fully funded basis and in Net Present Value.

Panel Final BackCheck Response (#1)

Concur.
In reference to Evaluator Response to Recommendation 4, if the impact to the final NPV calculation from re-running one of the frequent repair alternatives with and without the 15 percent cost increase is deemed significant, then all other alternatives should be re-run without the 15 percent cost increase. If the impact is not significant, state in the report that the costs were increased by 15 percent, but the cost increase did not impact overall plan selection.

Comment (#2):
The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.
Basis for Comment:
The report describes large volumes of sediment that will move into the navigation channel after a breach event. However, the Coastal Modeling System (CMS) numerical model results (CHL, 2007; p. 15, Figure 3.2) indicate minimal sediment movement through a jetty breach, even with the model strongly distorted to encourage movement. Similarly, historic breach events at the MCR inlet and region do not support the sediment movement volumes and rates assumed, nor the assumed sudden jetty failure, and the consequent requirement for emergency repairs and dredging. The assumed jetty breach sediment movement is also inconsistent with recent experience with dredged material disposal at the North Jetty. Approximately 400,000 cubic yards were placed at the site each year during 1999-2008, on average, comparable to some jetty breach scenarios. However, the sediment placed at the North Jetty does not appear to have affected navigation. Similarly, the reported "rapid deterioration" of the North Jetty from 1999 to 2004, when 100,000 cubic yards of sediment leaked through the jetty leading to the repairs in 2005, is not consistent with the assumed scenario of a sudden breach event and large sediment movement. Figures A1-252 to A1-254 of jetty breach sediment movement appear to be artist renderings, not products of analysis. The figures are misleading if they are interpreted as model output. Table 3-10 in the main report is presented but not explained, so there is no clear basis for the "Range of Volume Left in Channel" resulting from a breach of the North Jetty. There is no discussion of any hydrodynamic analysis or evaluation of morphologic changes and corresponding sedimentation of the navigation channel. Significant inconsistencies are present in the sediment transport discussion. For example, the documents discuss sediment disposal practices at the shallow water site (SWS), immediately offshore from the tip of the North Jetty. The EA notes, "Active monitoring and evaluation determined that 80% to 95% of the dredged sand annually placed at the SWS moves northward onto Peacock Spit" (dispersed to the north). However, the main report describes how rip currents along the north side of the North Jetty transport sediment towards the tip and then south into the navigation channel. This implies an unrealistic discontinuity in the sediment budget and sediment paths immediately offshore of the jetty tip. The sediment budgets and analysis are not consistent in different parts of the review documents, and seem to vary depending on whether the analysis is centered on dredged material disposal (emphasizing sediment movement onto nearby shores) or jetty stability (emphasizing sediment movement towards the channel). The jetties are described as functioning like "wingdams" preventing sediment movement into the channel. However, it seems more the case that the North Jetty shields the sands of Benson Beach from the dominant southwesterly waves preventing/slowing longshore sediment transport to the north, rather than south into the channel. Also, the process of sediment movement through a jetty breach is not at all like water through a dam break. The jetties are essentially a pyramid with only a small tip extending above water. What happens below water, with the sediments and foundations, is more central to the long term function and stability of the MCR jetties, navigation channel, and adjacent beaches. A better analysis of sediment transport is needed because the repair alternatives at present are an ever expanding pile of rock on an ever shrinking foundation of sand. The geological history includes more than 225 million cubic yards of dredging since 1956 from the MCR navigation channel, with most disposed offshore (EPA, 2009). The Southwest Washington Coastal Erosion

Study (Gelfenbaum, et al, 2006) concluded, “The carrying capacity of beach sands of Columbia River to the estuary has been reduced by approximately two-thirds over the last century.” The missing sediment from the system and ongoing erosion of the shoals that help protect the jetties all point toward a need for a more rigorous investigation of sediment transport and alternatives that could reduce the loss of sediment and subsequent project O&M costs.

Significance – High:

The rehabilitation project will not be successful if ongoing sediment loss continues and the shoals and jetty foundation wash away.

Recommendations for Resolution*:*

1. Eliminate or justify the unrealistic assumption of sudden jetty failure and large volumes of sediment rapidly moving into the navigation channel. Instead, compare alternatives based on life-cycle costs including ordinary jetty repairs and maintenance dredging costs.
2. Provide a real analysis of sediment transport. Include review and reference to data and findings from maintenance dredging records and the studies of the MCR prepared for the multi-agency Southwest Washington Coastal Erosion Study.
3. Describe how implementation of this project will reduce ongoing erosion of the shoals.

USACE Final Evaluator Response (#2)

CONCUR

The current “fix-as-fails” base condition will be revised to reflect current Corps O&M practices at the mouth of the Columbia River. As a result, a comprehensive sediment transport study will be unnecessary. Also, the report will be revised to clearly describe how scheduled jetty repairs will reduce ongoing erosion of the shoals.

The report describes an uppermost bound as the estimated worst case of what could happen with no intervention with a breach event occurring in winter and over a 3 month time period, resulting in a worst case shoaling consequence. This estimate is constrained to an approximate mid-length breach of the North Jetty only and rarely happens in the actual life cycle simulation. At a navigation project of this magnitude and importance, it is prudent to provide an assessment of the potential risk of a no action pathway for decision-makers to factor into their final decision at the project. The questions, “What could go wrong?” and “What might the consequences be of a failure?” are two questions essential to anticipatory engineering. Graduated levels of breaching potential and consequence were developed and incorporated within the event tree model and discussed within the report. Tables have been provided that summarize the potential number of significant breaches projected over the life cycle as well as the average expected shoaling expected from those breaches for the Base Condition and all of the alternatives.

This worst case estimate is based on experience from other locations where similar breaches have occurred, previous similar occurrences at the MCR, as well as the potential volume and gradient of sediment abutting the north side of the North Jetty. Previous occurrences at MCR where intervention was not undertaken (South Jetty, late 1920’s and Jetty A, 1950’s) indicated significant shoaling within the inlet, and constituted the impetus for rehabilitation of the structures in the 1930’s and 1960’s.

Within the limits of its application, the CMS model did show qualitatively that a significant flow field would be established through the jetty breach while prior to the breach, flow was aligned along the jetty. The CMS model was applied by ERDC to estimate the changes in circulation and associated sediment transport resulting from a breach of the north jetty. The hydrodynamic conditions used to drive the CMS model were observed during September 2005. The CMS model was run for a 6.5 day period. The results of the CMS model indicated that 0.2 meters of deposition may occur within the MCR channel 6.5 days after a breach within the mid-span of the north jetty. Projecting this breach-motivated deposition rate from 6.5 days to 3 months would result in 2.5 meters of deposition within the MCR channel, based on a summer forcing environment. During the elevated wave and water level conditions of winter, flow conditions through a simulated jetty breach would be of a much greater magnitude than that simulated by the CMS model. A significant jetty breach would increase in size and impact over a time frame of 3 weeks to 3 months and is expected to occur only during winter time in response to extreme storm conditions.

Modeling sediment transport (above and below water) coupled with morphological change within complex coastal inlets is still evolving in its application. While hydrodynamic models are fairly mature in their ability to simulate 2-dimensional flow patterns, they are still evolving in their ability to simulate 3-dimensional flow patterns.

Some extreme processes are too complex to be parameterized and cannot be accurately modeled; they have to reasonably estimated to arrive at an uppermost bound. The uppermost bound serves as the extreme potential estimate for the process (or response). The upper bound estimate is not expected to be encountered, but it is used to formulate a strategy for dealing with a given process-response-consequence scenario. The process of establishing an upper bound estimate is often undertaken in water resource engineering, and was done so for this project to evaluate the potential effect of a jetty breach. Due to the intervention measures built into the event tree (emergency repair and emergency dredging, if needed), the uppermost bound is not achieved in the MCR model for a breach event.

Portland District experience at Coos Bay has shown that once a deteriorated jetty cross section experiences increased overtopping as well as scour and wave loading, the transition time to a full jetty breach can be fairly rapid. In the case of Coos Bay, the breach developed over a number of days. At some point in jetty cross section degradation, the resilience of the cross section above water reaches a threshold value where it can transition quickly from a partial jetty cross section to a breached jetty. The onset of material passing into the inlet through the jetty through a damaged and eventually breached cross section occurs over a period of weeks to months.

The hydrodynamic flow path developed after a breach would be significantly different than current conditions during which North Jetty site disposal occurs. The CMS modeling effort (and the Coos Bay example) indicates a jetty perpendicular flow path in contrast to the jetty parallel flow path that occurs now. That jetty-perpendicular flowpath would not only take advantage of the large sediment sink of Peacock Spit but would also tend to transport the sediment directly toward the navigation channel which is in closer proximity to the North Jetty than the South Jetty.

All of the referenced sediment transport paths in the "Basis for Comment" are true and occur under a range of environmental conditions, due to the spatially variable nature of the morphology and the effect of circulation at this inlet. A small but distinct change in the morphology at this inlet (such as a jetty breach) can generate large changes in circulation and morphological response. Evidence can be provided (photos, model results, sediment transport study results, ODMDS performance, beach monitoring) that supports the sediment transport discussion in the report.

What would motivate the transport of sediment through a breach in the North Jetty is the gradient of sediment elevation on either side of the jetty and the gradient in circulation during much of the tidal stage. In addition, wave surge and other storm related effects cause localized and enhanced setup along the North Jetty and along Benson Beach. If a hydraulic connection is made from one side of jetty to another, circulation can occur through that breach during most if not all of the tidal cycle. The maximum level of channel deposition for the worst-case no.rth jetty breach scenario was estimated to be 6 meters, and assumed that such a breach would occur in November and continue un-abated for a 3 month period. Emphasis will be added within the report (and on graphics associated graphics) to clarify that the worst case-scenario is an extreme event and is not expected to occur. The morphology configuration resulting from the worst case jetty breach at north and south jetty is based on the expected volume release of the sediment (morphology) presently being held by the jetties and partial transfer through the breach. The resultant post-breach morphology shown in figures 1-33 and 1-34 account for the expected tidal flow and wave action acting on the gradient of sediment from one side of the jetty to the other and are intended to balance the transfer of sediment volume from onse side of each jetty to the other. The MCR breach event estiamtes are based on similar events occurring at Coos Bay, OR, Grays Harbor, WA, and barrier island breaches.

In the evaluation of alternatives we have considered to our best ability the continued evolution (reduction) of morphology at the MCR, based on previous observations as well as other reference documents. We have estimated those effects by estimating continued toe scour along the jetties and continued increase in depth-limited wave heights along the jetties due to morphology evolution. We are not proposing to extend the jetties to their fully authorized length because the morphology associated with that full length is gone. We are proposing, however, to hold the jetty heads in their present condition to provide the full jetty function and maintain the present morphology as much as possible.

With respect to the Washington Coastal Erosion Study (Gelfenbaum, et al, 2006) and the following statement: “The missing sediment from the system and ongoing erosion of the shoals that help protect the jetties all point toward a need for a more rigorous investigation of sediment transport and alternatives that could reduce the loss of sediment and subsequent project O&M costs.” We are undertaking that effort on a parallel path under the Regional Sediment Management program and will reference those studies by collaborative efforts of USACE and all stake-holders. However, deferred jetty maintenance can have a negative effect on morphology and proactive jetty maintenance can have a positive effect on maintaining the present morphology. Future conditions that have been evaluated institute adaptive management for jetty maintenance. Regardless of conclusions on sediment budget, structural actions are required to maintain the degraded 100 year old jetty system to prevent failure and loss of function. Proactive measures that encourage nearshore placement are a good idea and are being pursued under other authorities. Stabilization of the jetty head locations as well as application of spur groins along the jetty foundation are instituted with the express purpose of reducing the potential for morphology loss along the jetties.

1. **ADOPT NOW.** The base condition will be revised to reflect current Corps O&M practices at the mouth of the Columbia River. The jetty breach discussion in the report will be expanded to explain the difference between a small breach with no significant impacts and a larger breach which is not expected to occur. We will add a description for the logic that incrementally

assesses the response to a breach event along the north jetty, if winter dredging is needed to intercept sediment entering the navigation channel. The current study approach presently includes the life-cycle costs exhibited by ordinary jetty repairs and maintenance dredging costs. Although breaching can represent a significant consequence, its overall effect on the future life cycle performance of the MCR jetties is modest.

2. **NOT ADOPT.** Sediment transport and circulation models have been developed for the MCR and were utilized during the Major Rehabilitation study in a manner appropriate to a feasibility level of study. A catastrophic breach of any of the jetties is not considered to be a statistically significant possibility; therefore, a sedimentation analysis of a breach event is unnecessary. In addition, this type of catastrophic process cannot be accurately simulated in a model. Except for the Base Condition, which allows the jetty heads to continue to recede, the alternatives evaluated are not expected to have large impacts on sediment movement in the inlet. Stabilizing the jetty head positions will assist in anchoring the adjacent morphology in its present configuration. Construction of the spur groins should locally improve jetty foundation conditions and deposition along the jetty toe. Additional sediment transport analyses at this stage will not alter the alternative comparison.

3. **ADOPT NOW.** Language will be added to the report describing how scheduled jetty repairs with engineering features will reduce ongoing erosion to the shoals.

Panel Final BackCheck Response (#2)

Non-concur.

Notwithstanding the additional USACE work described in the Evaluator Response, concerns about the inadequacy of the sediment transport analysis remain.

The USACE response does not really add new information, or justify not doing a better sediment study. Specific points made in the basis of comment are not addressed in the Evaluator's Response.

A sedimentation analysis associated with the breach of any of the jetties needs to be conducted to ensure that all alternatives have been investigated.

Comment (#3):
The underlying assumption that navigational impacts will not occur is not substantiated.
Basis for Comment:
The report clearly explains why navigation benefits were not analyzed. The method used to calculate NED benefits is based on the assumption that navigation will not be affected; the economic analysis is therefore based on a least cost analysis. This assumption, however, is not supported by the analysis presented in the report. A North Jetty breach in the winter is assumed to result in immediate mobilization of sediment that may impact navigation. If this assumption is true, it does not necessarily follow that emergency dredging will successfully occur to enable deep draft vessel access. As stated on p. 3-14 of the main report, under base conditions, during winter months, emergency jetty repairs and emergency dredging may not be possible, potentially resulting in impacts to navigation until the emergency activities are completed. The main report also states (p. 1-48) that operating a hopper dredge at the MCR during winter months has not yet been attempted. The report does not address the impact of project construction and dredging activities on navigation. For example, the operation of a dredge in the MCR, especially under extreme winter conditions, could have an adverse impact on navigation in the MCR. The Panel was unable to fully understand the potential impacts on navigation of shoaling resulting from a jetty breach. Since navigation benefits were not evaluated, impacts to the MCR or Lower Columbia River (LCR) channels as a result of shoaling after a jetty breach, in the absence of emergency dredging, is only presented in qualitative terms such as "navigation would be significantly impaired" (p. A2-34). The extent of the impacts are not described (i.e., bar closure, vessels delayed due to having to use tides to access the channel, reduced under-keel clearances, vessel lightloading, etc.). Due to the dismissal of potential navigation impacts, no mitigation is defined.
Significance – High:
Conflicting assumptions concerning impacts to navigation invalidate the logic behind calculating NED benefits using a least cost analysis and impacts the selection of the NED, or recommended, plan.
Recommendations for Resolution:
1. Conduct a transportation cost savings analysis to calculate NED benefits. 2. Include a description of the expected channel depths available after a breach event, and in the absence of emergency dredging, include a description of the portion of the fleet using the channel that will be impacted by the resulting shoaling.
USACE Final Evaluator Response (#3)
CONCUR The base condition will be revised to reflect current Corps O&M practices at the mouth of the Columbia River. Hypothetical breach scenarios discussed in the report will be revised as described in the response to COMMENT 2. The Major Rehab report will be revised to remove all conflicting assumptions concerning navigation impacts.

1. **NOT ADOPT.** Revision of the base condition will eliminate the need for such an analysis. See response to COMMENT 5.
2. **NOT ADOPT.** Since a breach of any of the jetties is not considered to be a statistically significant, descriptions of potential fleet impacts is unnecessary.

Panel Final BackCheck Response (#3)

Concur.

The current base condition maintenance strategy conforms most closely with the fix-as-fails strategy described on p. A2-58 of the report. The revised base condition should reflect current Corps O&M practices, which are best described under the "Interim Repair Jetty Maintenance" strategy on p. A2-58 and by use of the interim repair thresholds presented in Table A2-12.

The Evaluator Response to Recommendation 2 indicates that "Since a breach of any of the jetties is not considered to be statistically significant, descriptions of potential fleet impacts is unnecessary." The Panel assumes this statement reflects the probability of a breach under the proposed revised base condition.

Comment (#4):
The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
Basis for Comment:
The SRB model results cannot be verified, as it is a custom-made engineering and economics model applicable only to this project and there is no means for the Panel to examine the inner workings of the SRB model and its internal calculations to assess its "adequacy and acceptability". It is not possible to verify model results, or to repeat the application of the SRB model because there is no User's Manual or detailed description of model inputs and how the model was applied for the Mouth of Columbia River project. Furthermore, the model has not been peer reviewed or tested. Without documentation of successful application, the Panel cannot validate the model or have confidence in the results. The SRB model internal calculations and logic are not a commonly applied method for calculating rubble mound structure reliability and damage. The model analyzes more than 600 variables, stacking process upon process, each with wide error bars, resulting in the accumulation of errors. Significant processes do not appear to be included in the model, such as armor rock breakage and deterioration and deep seated slip-circle failures. Figure A2-18a shows model output for jetty cross-section progressive damage. This figure provides one of the few insights into the inner workings of the SRB model. The figure indicates the physics and process of jetty decay are not modeled correctly because the output is not consistent with cross-sections of observed damage. The engineering evaluation does not include much about the physical modeling (i.e., wave tank results). It seems the wave tank model was used to develop the input and equations within the numerical SRB model. It is more conventional to proceed in the opposite sequence, to use a wave tank model to verify a final design concept and verify numerical model predictions. The wave tank model effort was substantial and likely yielded good insights. However, it does not appear that results were used to their fullest potential because the model output and findings were only applied through the SRB model process. The wave tank model results could have been used as part of an independent evaluation, providing an additional line of evidence along with other investigations, data, and findings. The SRB analysis should only be used as one of many tools in the alternatives evaluation rather than a substitute for the preliminary engineering design. Additional engineering analysis and design documentation needs to be provided as part of the preliminary engineering design report. Documentation through the preliminary engineering design process will lead to improved confidence and reliability of SRB analysis.
Significance – High:
The SRB model functions as a "black box" and does not allow an alternatives analysis that is clearly based on sound technical evidence of engineering design performance.

Recommendations for Resolution:
1. Move the SRB model to an appendix, as supplemental information, and assign it a weight of 10% in the evaluation of alternatives. No further work on the SRB model is recommended as part this project. 2. Include a detailed description of the SRB model application allowing verification of model calculations and how the model was applied to the Mouth of Columbia River project. 3. Demonstrate that the model has been peer reviewed and tested. 4. Move the calculations and elements of the study currently within the SRB model (such as rubble-mound damage, slope stability failure, design wave heights and water levels, economic calculations, and much more) out of the SRB model and provide as separate calculations that can be checked and verified. 5. Provide documentation of preliminary engineering analysis and design which would constitute the basis for the SRB analysis. The preliminary engineering analysis should be provided in the report, with details in appendices. Elements that appear missing or inadequate at this level of design include the following: o Design criteria and basis of design o Structure condition assessment and existing condition survey o Subsurface geotechnical investigation o Development of jetty repair/rehabilitation alternatives o Hydrodynamic analysis (waves, currents, sediment transport) specifically related to the alternatives o Determination of stone sizing for alternatives o Alternative evaluation • Development of evaluation criteria • SRB analysis o Detailed volume and cost estimate for the alternatives.
USACE Final Evaluator Response (#4)
NON CONCUR A custom-made engineering model is standard practice and a requirement for execution of a Major Rehabilitation study which requires the development of a life cycle performance event tree. The model simulates the project event tree and was intended to be applicable specifically to the MCR project and to provide input relevant to the comparison of various jetty structure maintenance options. (See attachment 1_EP_1130_2_500_exerpts for Major Rehabilitation guidance relevant to study execution.) Model documentation has been provided to illustrate how the model operates and how it was applied to the MCR project. Attachment 2_summarizes key locations in the Major Rehab report which addresses primary areas of interest. Attachment 3 simply summarizes the key elements of the life cycle simulation. Attachments 4 and 5 illustrate the project event tree and the model execution flowchart as well as the range of input data which was utilized in the model execution. Major Rehabilitation guidance directs us to probabilistically analyze structure performance modes (methods of failure), translate that to the expected physical degradation of the structure and the project, and summarize what the cost and consequences of that process might be to the functioning of the project. The apparent complexity of the model is directly related to the

intricacies of the project being analyzed as well as the fact that we are attempting to support a critical infrastructure decision relevant to a $200 to $400 million dollar federal investment as well as a $16 billion per year project function. We are analyzing 3 separate primary navigation structures (total length of approximately 7 miles) that have variable existing conditions, variable loading, and variable consequences of failure along each of their lengths. In the end the basic question should be "Does the analysis compare in a reasonable manner the various maintenance alternatives for the MCR structures and are the key performance categories adequately captured?"

The SRB model simulates the project event tree for the MCR jetties. The model tests the sensitivity of parameters used to define various jetty maintenance scenarios, rehab alternatives, and engineering feature. There are no off-the-shelf models that would perform a life cycle analysis of a complex project such as the MCR in any useful way. A great deal of effort went into capturing how this project has performed, performs now, and is expected to perform into the future; using variable loading and changing site conditions, both structurally and functionally. Simply stated, the basic elements of the MCR SRB model are jetty degradation and life-cycle consequences of jetty degradation. The model does not perform design calculations or syntheses of alternative attributes; these aspects of project development were performed external from the SRB model.

The successful application of the model is supported by calibration to 100 years of history as well as projecting reasonable project performance results into the future for a range of alternatives. The model results do not suggest either catastrophic future conditions or unreasonable maintenance requirements for a large infrastructure project subjected to heavy environmental loading and changing future conditions. (Attachment 6 provides the hindcast results for the 100 years of jetty and project evolution.) (Attachment 8 shows the future base condition for the North Jetty as estimated using the project event tree simulation (SRB model) as compared to the observed past maintenance history and other projected O&M rates based on the previous life cycle. Collectively, this figure shows the reasonableness of the SRB model projection for the Base Condition. Additional figures will be added to the main report to show results for the other jetties.)

Standard and approved rubble mound design engineering equations were utilized to assess reliability and performance. The design parameters and attributes were developed external to the model using standard Corps of Engineers practices, i.e. the model itself does not calculate design attributes for various alternatives.

All of the observed historically significant damage processes on the MCR structures include damages either due to slope failure or wave damage processes. A slope stability analysis (refer to Appendix B) determined that deep-seated slip circle failures were not a factor that affects jetty performance at this location. Armor stone breakage has also not be shown to be a significant damage process that needs to be included. (reference Appendix B) The cross section evolution figure noted is a generic representation of primary damage modes and their interactive effects. Damage processes shown are the same as documented and illustrated in the technical literature (reference CEM). (See Attachment 7 for standard representations of rubblemound damage processes as well as cross section examples of those observed processes on the MCR structures.)

Engineering calculations performed in the SRB model are:

- jetty cross section evolution under an annual wave loading scenario
- cumulative cross section damages leading up to either routine or emergency jetty repair
- quantity calculation of rock needed to repair the jetty
- time-varying reliability of the jetty at each 100 ft station
- quantity calculation of dredging needed due to jetty-damage related processes (breach or loss of jetty length)
- engineering calculations of costs to repair or dredging by year.

The products of the model are jetty repair and dredging volumes and costs given in 2010 dollars. That information is provided to the economist on an annual basis over the period of analysis for their economic calculation. External to the model, our economist calculates the BCR by taking the ratio of (Base condition cost- alternative plan costs)/Base condition costs. That economic information in conjunction with the estimate of reliability and other decision metrics is used in the final selection process of the alternatives. A recommended alternative is not selected in the model. The SRB model is a stochastic process model that attempts to account for the potential uncertainty in all of the parameters evaluated related to project performance. Through the Monte Carlo process the interaction of uncertainties contributes (interacts) to the final prediction to arrive at an informed and non-deterministic estimate for metrics of project stability and performance. (See attachment 1_EP_1130_2_500_exerpts for Major Rehabilitation guidance relevant to study execution.)

The physical modeling for the MCR project was used at two separate levels. The first was to evaluate and inform on initial design parameters/elements for cross section alternatives and stone sizes. The physical modeling was also used to provide input to the damage functions utilized to translate initial jetty cross section damage to continued degradation. The physical modelers and designers, and jetty construction experts/representatives worked together to refine and test design alternatives during the physical modeling phase of the study. The extent to which physical modeling was utilized in this study is considered adequate to a feasibility level of design and comparison of alternatives.

1. NOT ADOPT. The SRB model follows the project event tree simulation which is a requirement of the Major Rehabilitation Program Guidance. (See attachment 1.) The model is used to perform a life cycle performance evaluation which is required as part of the alternative analysis. The model is currently under review by USACE HQ; the results of the model will not be used in the Major Rehab Report if the model is not approved for use.
2. ADOPT NOW. Additional description of the model application was provided separately to the panel entitled “Model Operation Guide”. The calibration and verification of the model was demonstrated through the life-cycle hind cast process. The reasonableness of the model results for the MCR project to make future projections based on comparison with other calculation methods will be incorporated into Section 3.7.3. Attachment 8 illustrates the SRB model result projection for the Base Condition for the North Jetty in contrast to past O&M history at the project.
3. ADOPT NOW. The model review/testing has been conducted according to USACE requirements for this type of an application and study. Project specific models developed under the Major Rehabilitation program are not intended for multiple projects and Corps wide use. The SRB model was reviewed/tested at the District level and reviewed/tested through an Agency Technical Review.
4. ADOPT NOW. The model will remain as it currently is, and Section 3.7.3 will provide a description of the calculations that are conducted within the model and those that are calculated

external to the model. Section 3.7.3 will also provide information to demonstrate that individual processes emulated within the SRB model can be verified (Jetty damage, head recession, sediment volume into channel associated with head recession, shoreline recession related to head recession, channel shoaling related to shoreline recession, scour calculations, breach volume estimates). **5. ADOPT NOW**. These elements will be addressed as follows. Design Criteria and Basis of Design will be more fully summarized in Section 3.5, S tructure condition assessment and existing condition survey will be added to Section 1.4 a nd A1, Subsurface geotechnical investigation is addressed in Appendix B. Attachment 9 pr ovides additional information relevant to the request for subsurface investigations. Development of jetty repair/rehabilitation alternatives is currently addressed in Section 3.9, Hydrodynamic analysis summary will be added to Section 3.5, More details on the determination of stone sizing will be added to Section 3.5,The Alternative evaluation occurs outside of the model using model output as well as previously identified decision criteria.
Panel Final BackCheck Response (#4)
Non-concur. While many elements of the SRB model are appropriate and required per USACE guidance and standard engineering practice, it is not reasonable to fold it all together like this into one big model. Event-tree analysis, progressive damage calculations, and life-cycle costs are all good things to analyze. The SRB model effort seems to go off on a tangent from these elements, adding in engineering and other modules. The SRB model seems inappropriate based on USACE published guidance and does not support the project goals. The SRB model effort seems a Research and Development effort grafted onto an applied project. It has not been verified and validated and should not be relied upon.

Comment (#5):
The base condition, as formulated, does not represent the current O&M practice.
Basis for Comment:
The present and future base condition maintenance strategy for the MCR jetties, as currently described in the report, conforms most closely with the fix-as-fails strategy. Under this scenario, jetties will be allowed to deteriorate to the point that just-in-time repairs may not prevent a breach in the jetty, which would result in expensive, winter dredging activities. As the project is currently formulated, the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Historical maintenance efforts for MCR jetties are best described by an interim repair strategy. As a result of monitoring and advance repair activities, historically there have been no jetty breaches that have impacted navigation, nor has winter dredging been needed to maintain navigation. EP 1130-2-500, Appendix C, p. C-1 (USACE, 2006) states that for Major Rehabilitation Projects, under the base condition, "maintenance is increased as needed (but within limits) and components or sub-features are repaired on an emergency basis. This essentially represents the current O&M practice." Based on the report, this condition would resemble an interim repair strategy, rather than the fix-as-fails strategy currently described as the base condition.
Significance – High:
Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits for all action alternatives thus impacting the benefit to cost ratios.
Recommendations for Resolution:
1. Refine the base condition to more closely resemble the current O&M practice, in accordance with EP 1130-2-500, Appendix C (USACE, 1996).
USACE Final Evaluator Response (#5)
CONCUR The base condition utilized in the model will emulate past, current and future with/out project condition levels of maintenance. It is recognized by the PDT that the Jetties currently have a significant amount of deferred maintenance, and that condition was emphasized in the report. It is not the District's policy or intent to allow them to fail to perform their required function. The district will mobilize the resources required to prevent impacts to the channel under all but the most extreme series of events. **1. ADOPT NOW** The base condition will be re-run with the results incorporated into the main report. This will reduce the frequency of the SRB model predicting catastrophic jetty failure, which will also have an impact on both comment 2 and 3.
Panel Final BackCheck Response (#5)
Concur. The current base condition maintenance strategy conforms most closely with the fix-as-fails strategy described on p. A2-58 of the report. The revised base condition should reflect current Corps O&M practices, which are best described under the "Interim Repair Jetty Maintenance" strategy on p. A2-58 and by use of the interim repair thresholds presented in Table A2-12.

Comment (#6):
The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
Basis for Comment:
Potential breaching of the foreshore dune at the South Jetty root, to form a new connection to Trestle Bay, is discussed briefly in a few places, including a proposed cobble berm to mitigate this risk in the main report (Section 3.5.3.3, pp. 3-40 - 3-41, p. 7-1 and elsewhere). Additional analysis is appropriate given the consequences of breaching at this location. It is not clear what analysis has been conducted to evaluate the performance of the proposed dune augmentation. It is not known if the volume of material per linear foot is sufficient to provide the required width of cobble beach for stable conditions upon adjustment after initial placement. Maintenance requirements are not known for this design. Studies by DOGAMI (Allen, 2005) have been conducted on dynamic revetments for shoreline stabilization on the Oregon Coast but do not appear to have been applied. The breaching potential will likely increase with increasing shoreline erosion and loss of sediment from the system. However, potential beneficial use of dredged sediment is not analyzed as part of a design solution for a breach. Long-term erosion trends are assumed and are not adequately addressed in the report. The information provided is inconsistent in this area, with some sections saying the South Jetty dune erosion/augmentation issue will be addressed as part of a separate project, whereas other report sections include South Jetty dune augmentation as part of this project. Foreshore dune breaching has occurred at other coastal inlet navigation jetty structures along the Pacific Coast such as the South Jetty at Grays Harbor, Washington. Beach renourishment with dredged material and jetty structure modification improvements to prevent dune breaching were made with varying levels of success. It is not clear whether these similar project conditions and performance have been evaluated as part of the development and analysis of alternatives at the Columbia River South Jetty location.
Significance – High:
Breaching the dune at the South Jetty root appears to be a substantial risk, with more immediate consequences than breaching of a jetty because of the potential for forming a new tidal inlet with relatively rapid widening and deepening.
Recommendations for Resolution:
1. Either include the South Jetty dune augmentation/stabilization as part of the alternatives, and include costs and preliminary engineering, or state that it is not an element of the proposed work and is part of a separate project. Either way, potential breaching scenarios should be evaluated/modeled and included in the sediment transport and hydraulic analysis. This major investigation is the logical place to add studies of the MCR system (including jetties, navigation channel, estuary, and beaches). 2. Account for long-term shoreline erosion/recession trends in the design. 3. Review other jetty rehabilitation project solutions and performance at coastal inlet navigation facilities such as those conducted at the Grays Harbor South Jetty (Wamsley, 2006).

USACE Final Evaluator Response (#6)

CONCUR

The South Jetty Dune augmentation project while discussed in the MCR Major Rehab Report is a project that will move forward with or with/out the MCR project. The Dune Augmentation project will undergo a design phase where additional alternatives are reviewed and analyzed.

Figure A1-IPR6 shows the specific area of chronic erosion which has been affecting the MCR South Jetty root since the late 1970s. The intertidal zone has receded landward ~40 ft during 2003-2007, reducing the protective foredune along the south jetty root. The 35-ft high foredune protects the backshore (elevation 15-18 ft NAVD) from wave surge action during storms. If the foredune is breached, the backshore will be rapidly eroded; at a rate much higher than the present foredune recession. Without abatement of the present foredune erosion, it is estimated that the Pacific Ocean will establish hydraulic connectivity with Trestle Bay in 6-113 years from 2011, and threaten inlet stability. Two alternatives were investigated at an appropriate screening level, as described below. The Cobble Berm Foredune augmentation was selected based on the attributes described. Figure A1-IPR6 shows a range in proposed options for augmenting the foredune within the erosion embayment, in terms of cross-section template and estimated aerial configuration. The two (2) options for south jetty foredune augmentation were developed based on potential variation of the implementation strategy to achieve the objective which is to stabilize the foredune within the erosion embayment adjacent to the south jetty. To adequately protect the foredune during storm conditions, the template for both template options requires that the top of fill (crest) extend vertically to 25 ft NAVD and have an alongshore application length of ~1,100 ft extending southward from the south jetty root. The constructed template crest would be 10-15 ft above present beach grade and have a 1V:10H slope aspect, from crest to existing grade.

<u>SAND Berm Foredune Augmentation</u>: Augmenting the south jetty foredune using a SAND fill template will require placement of ~225,000 cy of sand. Maximum crest width of the SAND fill template is estimated to extend 400 ft seaward from the seaward base of the present foredune. Construction of the SAND berm augmentation would require 4-8 weeks. Two options may be available for placing the SAND fill material. The gradation of the sand fill material will vary from fine sand to course sand depending upon the source of the material Sand procured from upland sources would be placed using haul trucks and dozers; in this case the sand is more likely to be medium to course sand. Upland sourced sand would be transported on surface roads, through Ft. Stevens Park to the project site to a beach access point at the project site. There is a potential for the sand fill material to be procured from MCR or LCR navigation channel during O&M dredging. The dredged material (clean sand of variable gradation, 0.1 – 0.3 mm) would be pumped ashore, to the south jetty root, using a hopper dredge "pump-ashore" method. The hopper dredge would likely pump-off sand from the interior area of Clatsop Spit near Trestle Bay (CRM 6). The south jetty hopper dredge pump-off area would be located near the jetty stone marine delivery area proposed for South Jetty Rehabilitation. The sand would be pumped through pipeline (18-24 in diameter, for a distance of 1.5 miles during the summer season. A booster pump may be needed at mid-span. The dredged sand would be hydraulically placed at the project site; with dozers used to re-grade the material to the construction template. The pump-ashore method has been used to place MCR dredged sand along the north jetty foredune to stabilize the north jetty root and protect it from wave surge action. A SAND

berm template will be reformed by wave-surge action. The coarser the material, the more stable the berm will be over time. Over time the slope of the sand berm would be flattened to perhaps 1V:70H. If the south jetty is rehabilitated with spur groins, the resilience of the south jetty root and the sand berm will be increased. If the south jetty is not rehabilitated, the sand berm may require maintenance on a periodic basis of 3-6 years; assume 70% replacement volume.

COBBLE Berm Foredune Augmentation: Augmenting the south jetty foredune using a COBBLE fill template will require placement of ~60,000 cy of cobble material. The Gradation of the cobble fill would span 10-200 mm. Maximum crest width of the COBBLE fill template is estimated to extend 70 ft seaward from the seaward base of the present foredune. Construction of the COBBLE berm augmentation would require 2-6 weeks. Cobble fill material would be procured from upland sources and placed using haul trucks and dozers. The cobble material would be transported on surface roads, through Ft. Stevens Park to the project site to a beach access point at the project site. The cobble berm would be more resistant to wave action than a berm constructed using sand. Over time the slope of the cobble berm would be flattened to perhaps 1V:20H. The areal configuration of the cobble berm should preclude significant alongshore displacement. Although offshore transport of the cobble material is expected to be much less than for sand, over a significant period of time, the cobble berm will lose material. The cobble berm would emulate the foreshore conditions similar to those at Seaside, OR 18 miles south of the south jetty. If the south jetty is rehabilitated with spur groins, the resilience of the south jetty root and the sand berm will be increased. If the south jetty is not rehabilitated, the cobble berm may require maintenance on a periodic basis of 4-10 years; assume 40% replacement volume. The advantages of the cobble berm are that it would require less material than a sand berm, exhibit more resiliency, and have a smaller construction foot print. A disadvantage is that the unit cost for cobble material may be higher than for sand.

The timing of this action is expected to be within first 8 years of the proposed jetty rehab project (after 2011). It must be noted that nearshore placement of MCR dredged material within the proposed South Jetty Site (SJS) nearshore disposal site would mitigate the erosion of the south jetty root area. This SJS would complement the proposed foredune augmentation and help ensure balance of the sediment budget south of the south jetty. The SJS should not viewed as a replacement for foredune augmentation.

1. **ADOPT NOW** We will clarify that this is part of the Base Condition which will be implemented regardless of the outcome of the MCR Jetties Major Rehabilitation project. Within a broad assessment we have determined that the consequences of a breach in this area would be high enough to warrant preventive measures as proposed now. Preventative action has been determined to be merited in this location. Potential breaching scenarios and consequences will be evaluated in the design phase of that action.
2. **ADOPT in FUTURE**. L ong-term shoreline erosion/recession trends will be more closely evaluated in the design phase. S hort-term observations since 2003 indicate a rapid recession rate of the foredune is now occurring within the local embayment / erosion zone which extends several hundred meters south of the South Jetty.
3. **ADOPT in FUTURE**. Related studies and reports will be reviewed for inclusion into the DDR.

Panel Final BackCheck Response (#6)
Concur. The shoreline erosion/recession trends should be accounted for now, at an early, high level planning stage and implemented as part of this project.

Comment (#7):

The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.

Basis for Comment:

The document "design_criteria_info.doc" is vague. It discusses "50 year alternatives," but the term is not defined. It could mean many things, including the following:

1. The project life is 50 years, with complete replacement assumed after 50 years.
2. Design jetty repairs that have the least life-cycle costs over a 50 year period.
3. The economic planning horizon, benefits and costs, are calculated for 50 years.
4. Design to withstand a series of storms over a 50 year period.
5. Design to withstand a single 50 year return period storm event.

Section 3.5.2.1 (Cross Section Intent and Design Philosophy) states, "The repair template must … allow the maximum repair within funding limitations." This indicates the main design criterion is to provide the most repair possible within a budget limit, rather than design to withstand environmental loads and forces. The "funding limitations" are not stated, yet appear to be behind many of the design and planning decisions. Using funding limitations as a design criterion is not the same as an engineered design that meets environmental loading criteria. The funding limits design criteria are not consistent with the environmental loading design criteria in "design_criteria_info.doc."

Note that a 50 year project life does not necessarily mean one should apply a 50 year return period event for the design environmental criteria. For example, a petroleum development platform may have only a 35 year project life, but the project may be designed to withstand a 100 year return period storm event or longer. The consequences of jetty failure should be considered in establishing the design criteria. ISO standards are sometimes applied in practice, but do not seem to be included in this work. Additionally, USACE (1995; paragraph 2-4) states rubblemound structures should be designed to successfully withstand the conditions that have a 50% probability of being exceeded during the project's economic service life. The economic service life needs to first be established as a criterion and then the design storm formulated to meet the acceptable risk level for that service life.

A span of 50 years may be appropriate for an economic planning horizon; however, a 50 year project life or a 50 year return period storm event does not seem reasonable for engineering design considering the importance of navigation through the MCR. The structures should be designed to last indefinitely, as permanent structures, with regular maintenance requirements estimated and included in an economic analysis.

The 50 year criterion may not be consistent with parts of the report that mention a longer period of time. The SRB model discussion in Appendix A2, p. 78 states, "The period of analysis for future condition simulations was 64 years (2006 to 2070) for the North Jetty and Jetty A and 63 years (2007 to 2070) for South Jetty."

Appendix A2 (p. A2-8) states, "The MCR jetties were constructed to achieve an expected service life of 50-100 years," and concludes that 0.7% per year is the expected maintenance cost based on the 50-100 years service life. The 50-100 years service life, and associated 0.7% figure is used to inform the analysis and to demonstrate a lack of maintenance. However, the original 50-100 years service life, and 0.7% annual expected maintenance cost are arbitrary assumptions. The historic assumed service life and maintenance needs are not supported by the information presented, and largely irrelevant to today's design and maintenance criteria.

The design criteria, if any, from 100 years ago when the jetties were built are not presented and previous maintenance are considered an operational cost. Analysis of past maintenance also may distract from the main problem afflicting the jetties: poor design 100 years ago, not deferred maintenance.

The original builders, working before the development of modern coastal engineering methods, underdesigned the jetties with only 7 ton armor rock, at their angle of repose of 1.25h:1v, or steeper. In addition, they constructed the immense structures on ever shifting sand shoals, locating them where the shoal happened to be at the time of construction, without adequate design features to account for shifting channels and currents.

The starting assumptions and criteria and alternatives are so narrowly constrained that there is questionable value in much of the analysis. The Major Rehabilitation Evaluation study is set up so that the end result is always the same; more rock within the existing jetty footprint.

Conventional coastal engineering practice for a project of this scope would include the following:

1. Analysis to determine how much jetty is really needed today to maintain the navigation channel at reasonable cost. The Panel questions whether all 9+ miles of jetty are optimal. There has been no upward trend in maintenance dredging volumes since 1956, despite continued jetty tip recession, which indicates shorter jetty lengths would be equally functional at less cost.
2. Evaluation of alternatives that are not constrained to the original footprint, not built to the maximum crest elevation and authorized length feasible, not constrained only to rock, and discussed or considered beneficial use of dredged material as a design element.
3. Evaluation of durability issues and lessons learned from related projects. For example, the Dover Pier in England has lasted well over 100 years. Similarly, the Humboldt Bay jetties and Crescent City jetties in Northern California have effectively stopped jetty head recession using 40 ton dolos concete armor units, and the Japanese are building breakwaters with 90 ton dolos concrete armor units.

Significance – High:

The lack of criteria prevents NED analysis and evaluation of whether the structure design meets standards.

Recommendations for Resolution:

1. Establish conventional project criteria including project life, standards of performance and function to be met, and environmental loads and return period events, which are part of conventional coastal engineering design practice. Document in a Preliminary Design Report.
2. Establish Design Environmental Conditions that have a specific return period.
3. If unable to meet the design criteria due to budget limits, state the budget limits as a criterion, and estimate what the equivalent design life or expected performance will be for the compromised design.
4. Expand the starting assumption to allow:
    a. Beneficial use of dredged material as a component of jetty rehab.
    b. A design outside the existing jetty footprint
    c. A design that may allow jetty head recession up to a point when maintenance dredging needs increase.
    d. A design that can include a partially submerged jetty cross-section.

5. Use a longer return period than 50 years for the design environmental criteria and consider ISO standards.
6. Consult with Dover Pier representatives and other jetty builders to discuss durability issues and lessons learned from their project in order to benefit the MCR project.

USACE Final Evaluator Response (#7)

NON-CONCUR

Feasibility level design templates were developed using standard deterministic analysis techniques, supplemented by physical model input. The goal of the study is to identify the optimum repair and rehabilitation strategy contrasting initial and up-front costs vs recurring maintenance costs over the 50 year life cycle.

We have an ensemble of offshore storm wave events and nearshore water levels spanning from the sub-annual to the 50 year occurrence interval for the MCR project area. Various cross section alternatives (varying levels of robustness and maintenance strategies) were evaluated and then assessed in terms of their least cost and reliability characteristics over the planning period. Alternatives analyzed in this phase of study were commensurate with a feasibility level of study providing enough detail to identify key differences between performance and cost of alternatives. A more detailed, focused and rigorous design effort will be conducted in the next phase of study, the detailed design phase.

In the MCR climate, zero damage design is not achievable. Rubblemound structures in the PAC NW will incur heavy overtopping and can also suffer from foundation scour and below water slope adjustment. However, the flexibility of the rubblemound structure and its ability to heal itself after incurring some damage is critical. In contrast, a concrete armor unit structure would be more vulnerable to individual armor unit movement as well as overtopping forces.

In terms of cost optimization, cross section alternatives seek to avoid requiring a higher crest, a flatter sideslope, or extremely large armor units since all of these issues result in either much higher up-front costs and/or constructability issues. The feasibility design cross sections developed utilize standard design criteria to withstand the expected environmental loads and forces. Staying on the relic stone base minimizes the cost of repair or rehabilitation and ensures a stable base to tie in the alternative with the existing structure.

Beyond that ,we have to be able to identify a range of reasonable repair options over the planning horizon for the MCR jetties which is 50 years, commensurate with maintaining jetty function and performance. This was accomplished starting with the identification of a minimum template application along the jetty length which specifically fits on top of the existing structure. Graduated levels of cross section application above that minimum template were then applied along the jetty length as well as various combinations of the cross section graduated levels.

The composite alternatives (shown in figures 3-49 and 3-54) and discussed in section 3.10.3, provide alternative transition points along each structure from a less robust cross section application to a more robust cross section application. The study evaluated 5 composite alternatives for the South Jetty and 4 composite alternatives for the North Jetty in an effort to optimally address the variable loading climate along each structure.

The period of analysis for this study is the future economic service life (50 years) plus the project implementation period, as prescribed by the planning guidance (ER-1105-2-100). The PDT has developed a range of alternatives that optimize life cycle metrics over that period of analysis and that have the additional criteria of minimizing the risk of unsatisfactory project performance (loss of project function). The project event tree simulation and risk-based analysis as dictated by Major Rehabilitation guidance translates the various repair and maintenance strategies into their respective life cycle cost streams.

The evaluation procedures for major rehabilitation require the Districts to use risk-based benefit-cost analysis incorporating the existing and future risk of "unsatisfactory performance" of structures and equipment. These risks are then combined with estimates of the costs of unsatisfactory performance to generate an expected reliability based cost. Alternative rehabilitation strategies are then proposed to reduce this cost. Each alternative can either change the risk, change the cost of unsatisfactory performance or both. A complicating difficulty is that the analysis must be carried out over the "life-cycle" of the project, up to 50 years. That is, the cost estimated is the present value of all costs associated with the operation, maintenance, and repair of the facility where each cost is weighted by the probability of occurrence. (EP 1130_2_500).

The period of analysis analyzed in the SRB model starts from a point of knowledge of the jetties present condition connected to the last full survey of the jetty structures (2006), includes the implementation time frame and the economic service life. However, all alternatives are compared over the same time frame.

Despite the formidable challenges faced by the engineers for the original MCR jetties (severe working environment), lack of established design criteria, and limitations encountered during initial construction, the MCR jetties have performed rather well during their previous life-cycle. While the original project authorization was expected to be for a 50 year life, by default the service life of the original jetty structures has extended to an approximate life of 100 years. The jetties were originally constructed and repaired over the life cycle using progressively larger stone sizes and larger design templates as design criteria changed and equipment capacity evolved. At the same time, the surrounding loading climate was being altered. The 0.7% per year of expected maintenance cost was estimated to attempt to quantify how well the structures have survived. Standard practice is to expect a certain annualized replacement rate on a rubblemound structure. We calculated the approximate repair rate to determine how well the project appeared to be performing in relationship to the realized maintenance rate.

Since the original design criteria for the construction of the jetties over 100 years ago was not available and could very possibly have been constrained by stone size availability as well as transport and equipment restrictions, the information available to assess jetty performance was the maintenance history along the jetty length. While the design criteria were not known, we do have a complete record of the cross section construction parameters. Through the course of this study we have determined how well have the jetties have performed to date. This provides context to necessary stone sizes and cross section dimensions along the length of each structure, answering the question of whether the jetties have adequately performed over their life span under the historical maintenance scenario. We needed to be able to answer if it is feasible to continue to maintain the jetties in the present and historical manner without other extreme measures.

While it was important to identify a potential range of alternative options, fully utilizing the existing structure and existing federal investment in order to minimize the additional repair/rehabilitation cost was essential. That goal as well as the relative success of the past 100 years in jetty stability led to a range of alternatives that built on top of the existing structure and fully utilized the relic stone base. Other similar Pacific west coast jetty rehabilitation examples illustrate the critical design alternatives characteristics: (1) maintain compliance and flexibility under significant design loading and (2) take full advantage of the already established stable relic base. In the more heavily loaded reaches of the structures, either modifying the cross section to extend off of the existing footprint for added cross section stability and/or utilization of other armor types have been included as options.

The major rehab guidance directs comparison of maintenance strategies for the structures we have in place. Modifying the project layout is not part of the Major Rehab goal. Extensive hydrodynamic modeling was conducted to evaluate re-building a portion of each jetties authorized length. The model results showed that the project performance improvements connected with rebuilding the jetty length were not sufficient to offset the extreme costs of building out into the Pacific. Early on in the Major Rehabilitation study it was determined that for this study, stabilization of the jetty heads at the current location was recommended in order to not impact navigation as well as environmental and sedimentary processes.

We include several alternatives that extend beyond the existing footprint. We also adjust the crest elevation at various locations below the previously-constructed crest elevation; however, a minimum crest elevation is required to limit overtopping damage and allow safe construction access. The decision was made not to rebuild the jetties out to previously authorized lengths. While the majority of the repair work can be accomplished by the more cost-effective stone armor units, in some locations, concrete armor units may be considered. This will be evaluated specifically for the jetty heads during the next detailed design phase. While the use of dredged material as an additional benefit for the morphology is being pursued under a parallel effort, it cannot be guaranteed to be implemented due to regulatory challenges and in addition, if implemented the immediate short term benefits will not take the place of structural fortifications of the jetties. We are considering concrete armor units for the more heavily loaded jetty head designs to be more fully explored in the next detailed design phase.

1. **ADOPT NOW.** by providing additional design documentation and clarification. This report represents a feasibility design pursuant to Major Rehabilitation guidance. The more detailed design effort will occur in subsequent detailed design reports. The design wave and nearshore water level environment will be defined in terms of estimated return intervals. A table will be prepared that summarizes the design attributes for alternatives as defined by the assumed loading (event) parameters, including the expected maximum loading event. Additional explanation will be provided that clarifies why alternative development (for rock armor alternatives) cannot be limited by a “0 damage” design requirement: Due to the severity of the forcing environment, armor production, transport, handling limitations, and construction equipment/placement limitations. Because of these limitations, some areas of the MCR jetties have alternatives that can sustain damage and still function for a given period of time before requiring maintenance. Along some of the most extreme jetty areas, CAUs may need to be used in place of rock armor. M-CASES cost estimates for CAU cross-sections have been made, which show that CAUs may be cost effective when compared to the maximum-sized rock armor units that are constructible. However, if CAUs are used, then the “0 damage” design requirement will be enforced for alternative development: CAUs become ineffective if damaged or

displaced.

2. **ADOPT NOW**. by providing definition of design environmental conditions that have already been established and have been used in this study. It is worthwhile to note that when the estimated 50-year and 100-year offshore wave event is transformed to the jetties, the nearshore wave height (Hmo) at the jetties increases less than 0.1 meters as compared to the 25-year observed offshore storm condition (largest observed storm condition). A discussion will be added to integrate the description for the return period of the present offshore wave environment, the return period of the storm induced water levels along the MCR jetties, the depth-limited natures of large waves approaching the nearshore waters along the jetties, and the estimated return interval for waves affecting the jetties.

3. **NOT ADOPT**. The event tree and the SRB model were used to estimate life cycle costs relative to initial investment and repair strategies.

4. **NOT ADOPT.** Beneficial use of dredged material is being evaluated along a parallel effort but cannot take the place of structural repair in this loading environment. Several alternatives already extend beyond the existing jetty footprint. Jetty head recession beyond the current station was determined to be unacceptable due to potential navigation, sedimentary, and environmental impacts.

5. **NOT ADOPT**. This Major Rehabilitation feasibility design follows normal Corps guidance for rubblemound structure design. A description of the maximum estimated loading event to affect the MCR jetties (in terms of water level and wave height) will be added to an appropriate location within the report.

6. **ADOPT in FUTURE**. The MCR jetties have over 100 years of performance and evolution to inform the current and future maintenance strategies at this location. Stone durability has not been found to be an issue with the damage processes. Further design investigations and development will occur during the detailed design phase. The PDT will review the available literature for Dover Pier, and assess lessons learned from that project as they may be applied to the MCR jetties"

Panel Final BackCheck Response (#7)

Concur

The report and SRB model do not incorporate specific design elements such as a 100 year return period wave or water level.

Note the following from USACE "Engineering and Design: Life-Cycle Design and Performance. Engineering Regulation", 1997, 1110-2-8159.
"...design decisions will be consistent throughout all project phases, including value engineering studies, and will be based on a minimum project service life of 100 years for major infrastructure projects such as locks, dams and levees.", and
"Major Civil Works projects can have an indefinite service life."

The report is not consistent with this guidance. However, it is understood that USACE may interpret the regulations differently, and the project team sees a 50 year service life as acceptable if there are no life-safety issues involved.

The standard of practice for coastal engineering requires defining a storm event, such as the 100 year return period waves and water levels, then designing the structure to withstand that event.

The assumption that stone durability is not an issue is not consistent with standard coastal engineering practice.

Literature Cited:

USACE. (2005). Design of Coastal Revetments, Seawalls, and Bulkheads. Department of the Army, U.S. Army Corps of Engineers. Manual EM 1110-2-1614. June.

Comment (#8):

The models and analyses of jetty failure do not include all significant processes.

Basis for Comment:

The SRB and STWAVE models cover many significant processes and variables that affect long-term jetty stability; however, some variables and processes are missing that should be presented in the SRB model and the Major Rehabilitation Evaluation Report:

- Armor rock breakage, rounding and wear, which can significantly affect jetty performance, do not appear to be included in the analysis.
- Deep seated slip surface failures through the jetty section, a global failure similar to a landslide, also do not appear to be analyzed and may be a significant risk.
- Wave height in combination with currents can cause significantly higher sediment transport rates than waves only or currents only. It is not clear if sediment transport analysis, considering both waves and currents acting together, has been done.
- Long-term changes in outlet channel morphology do not appear to be analyzed. The process of jetty decay through tidal channel scour appears different at Jetty A than at the North or South Jetties. Tidal channel scour at the tip of Jetty A will not be mitigated by adding spur groins, therefore a different system will need to be designed at Jetty A and accounted for in the jetty performance analysis.

The STWAVE model is not sufficient for modeling detailed wave transformations. Important processes such as wave structure interactions, refraction, and diffraction are incorporated in STWAVE using approximate methods. Other models like BOUSS-2D and CGWAVE are readily available and model the physics of these important processes more directly. STWAVE is appropriately applied as a regional wind-wave generation model for regions without a complex bathymetry. However, the Mouth of the Columbia River morphology near the jetties and navigation channel is complex. A phase-resolving wave transformation model such as BOUSS-2D or CGWAVE should be applied at this level of design in addition to STWAVE.

Significance – High:

The analysis of potential jetty failures, waves, currents, and sediment transport is incomplete for this level of design, and may result in significant errors in the evaluation of alternatives. Errors could include underestimating the design wave height, leading to undersized armor rock, excessive maintenance requirements and structure failure.

Recommendations for Resolution:

1. Estimate future repair needs and armor rock characteristics based on past performance of rock at the jetties. This requires a more detailed survey of existing condition, including quantifying existing armor rock size, gradation, and shape.
2. Analyze foundation stability based on measured geotechnical properties. A subsurface geotechnical investigation, including borings and soil testing, is recommended.
3. Provide a design concept for scour protection at Jetty A and check its stability against design environmental criteria, including specific current speed and wave height.
4. Apply models and use analysis methods to investigate sediment transport patterns and jetty foundation erosion under a combination of both waves and currents.
5. Supplement the STWAVE model with a wave transformation model such as BOUSS2D or CGWAVE to help determine design wave heights near the jetties.

USACE Final Evaluator Response (#8)
NON-CONCUR The performance and failure modes analyzed in this study are representative of the significant failure modes impacting the structures. We can add discussion which clarifies the relative role of armor rock durability in overall structure performance, however, this has not been found to be a significant process on the MCR structures. The deep seated slip surface failure mode was investigated and also found to not be a contributing factor to the failure processes at the MCR jetties. Refer to Appendix B for a discussion. We have an extensive amount of existing geotechnical information in the area that provides us with a good understanding of the nature and properties of the subsurface conditions and enables us to conduct a preliminary design without the need for additional site-specific explorations. This information includes recent vibracoring in multiple areas around the jetties, geophysical studies including subbottom profiling, side scan sonar, and multibeam surveys, all which provide both direct and inferred information on the subsurface material properties. These investigations suggest materials on which the jetties were built consist of well sorted fine- to medium-grained sand with some thin interbedded mud layers. While some jetty subsidence may have occurred during or shortly after original construction, little to no additional settlement is expected during future repairs indicating the foundation is firm under the jetties. Damage to the jetties has been documented by over 100 years of past performance, with numerous repairs having been conducted through the years. The type of damage observed is consistent with wave loading and scour damage affecting the toe of the jetty, as stated in Appendix B. The proposed alternative actions are consistent with previous repairs, adding stone to the existing cross-section by less than 5% of the total mass. Under these conditions, it is unlikely that the extra weight would affect the existing rubblemound base. No instances of deep-seated slip surface failures have been recorded during the life of the jetties, and are considered unlikely to occur as a result of upcoming repairs. The USGS DELFT model and the ERDC CMS model included the interaction of waves with currents when evaluating the potential for sediment transport within the inlet and around the jetties. In addition, historically-observed scour rates were applied along the length of the jetties in order to project into the future, see tables A2-6 through A2-7 for projected future scour rates along each jetty. Additional text will be provided that explains how the scour rate values in the tables were estimated. Bathymetric comparisons have shown that the tidal channel morphology at the end of Jetty A has stabilized. This analysis will be further clarified in the report. The spurs at Jetty A are intended to influence the scour and rip currents that occur along Jetty A. The future scour that will occur along jetty A has been estimated and is incorporated in the life cycle assessment of Jetty A. The vertical extent of the scour hole at the head of Jetty A has reached an equilibrium condition based on the current configuration of all of the jetties and the configuration of the MCR inlet, which is another reason to stabilize all of the jetty lengths at their present location. The seaward end of Jetty A has been rebuilt numerous times resulting in a relic stone base that has stabilized along with the scour hole. Our proposal to not rebuild the Jetty A head out to authorized length prevents the complications of trying to build out into the scour hole and avoids increasing circulation forces at that location. The significant relic stone base as well as the addition of the spur groins will add resilience to the morphology surrounding Jetty A. ERDC conducted a comparison of BOUSS-2D results to STWAVE results at the MCR. The

model results compared favorably for this level of study. While STWAVE may slightly over-predict some of the incident wave heights, this application was appropriate at the feasibility level and for the comparison of the alternatives, STWAVE results compared more favorably to the actual wave observations at the project site. For the extreme events modeled, no wave observations were available for comparison. Use of STWAVE allows for the incorporation of wind and for the transformation from the offshore to the project site. Use of STWAVE results was selected in order to provide conservative results and will be followed up in the more detailed design phase with further analysis.

1. ADOPT NOW. This has already been calculated. Further documentation of analysis and results will be provided. A table will be provided that documents existing condition of the structure, template deficit, template and armor stone characteristics, and future repair needs. Portland District rock standards ensure that rock durability is not a significant issue regarding jetty cross section longevity and/or failure. The life cycle performance analysis that has been conducted during this study already estimates future repair needs based on historical performance, existing conditions, damage and failure modes, site specific loading, and graduated levels of repair robustness.

2. NOT ADOPT. Appendix B identified the foundation and geotechnical factors impacting jetty stability. The geotechnical information requested in the comment to be presented in this report is beyond the level of effort normally required for a feasibility level study such as this, where only preliminary designs are identified, as indicated in EM-1110-2-1100, Coastal Engineering Manual. Damage to the jetties has been documented by over 100 years of past performance, with numerous repairs having been conducted through the years. The type of damage observed is consistent with wave loading and scour damage affecting the toe of the jetty, as stated in Appendix B. We anticipate that a more extensive review and analysis of the foundation parameters will be accomplished in the DDR phase, which may allow us to optimize the alternatives.

3. ADOPT in FUTURE. We have accounted for the historical evolution of Jetty A and its surrounding morphology to the extent necessary for this feasibility level analysis. The substantial relic stone base at Jetty A and the construction of the new jetty head at 400 ft landward of the authorized length will provide sufficient stability for the alternative suggested.

4. NOT ADOPT. This has already been done. The USGS DELFT model and the ERDC CMS model included the interaction of waves with currents when evaluating the potential for sediment transport within the inlet and around the jetties. In addition, historically-observed scour rates were applied along the length of the jetties in order to project into the future. See tables A2-6 through A2-7 for projected future scour rates along each jetty. Additional text will be provided that explains how the scour rate values in the tables were estimated. Further analysis can be conducted in the final design effort.

5. ADOPT in FUTURE. ERDC conducted a comparison of BOUSS-2D results to STWAVE results at the MCR. The model results compared favorably for this level of study. BOUSS – 2D tends to under-predict the waves slightly and STWAVE tends to over-predict the waves. STWAVE results compared more favorably to the actual wave observations at the project site. For the extreme events modeled, no wave observations were available for comparison. Use of STWAVE allows for the incorporation of wind and for the transformation from the offshore to the project site. We chose STWAVE results in order to provide conservative results and will

follow up in the more detailed design phase with further analysis.
Panel Final BackCheck Response (#8)
Non-concur. It is good to see that the BOUSS-2D wave model was applied. Adding this to the report will add a lot of value. However, there remain many problems with the proposed USACE plan to resolve the issues. The panel does not share the project team's assessment that "We have an extensive amount of existing geotechnical information". Appendix B is not adequate as a sub-surface geotechnical investigation for a project of this scope. Appendix B is not consistent with conventional engineering practice, including guidance in USACE manuals: TM 541-1I, EM 1110-1-1802, and EM 1110-1-1804 "Engineering and Design - Geotechnical Investigations". Appendix B is not consistent with the basic standards described in EM 1110-1-1804. Missing information includes boring logs, laboratory and in-situ test results and recommended design values for shear strength and other properties. Future work should be based on quality field data and there is much to be done, not just borings. Panel recommends that project time and budget going forward should prioritize collecting quality field data as a first step, not revising and adjusting the SRB model.

Comment (#9):
The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
Basis for Comment:
The design alternatives presented in the document are limited to the repair and rehabilitation of the jetties within the present configuration. The Panel is concerned about the adequacy of the alternatives analysis and the limited range of alternatives considered. NEPA Section 1502.14 requires a rigorous examination of all reasonable alternatives to any proposal and justification of eliminated design alternatives. The Panel finds that there is little examination of alternative approaches to the principal function of the MCR jetties, which is to secure a consistent navigation channel across the bar at the MCR. As such, the narrow scope of alternatives presented weakens this project. Insufficient information is provided to justify limiting the improvements to the existing footprint. For example, the report does not provide the technical basis for maintaining the 1895 jetty design, length, and orientation to the exclusion of considering other configurations. Considering reasonable alternatives, under NEPA guidance, would allow USACE to use hydrodynamic modeling tools to evaluate alternatives such as the use of weir jetties (Seaburgh, 2002) and other sediment management methods that facilitate bypassing sediment at coastal inlets, as well as low wave and high wave depositional basins in a manner which may reduce long term operation and maintenance costs. The impact of not considering additional alternatives leaves the overall justification of the project less defensible and may lead to questions of the overall merit of the rehabilitation project
Significance – Medium:
Consideration of alternatives beyond rehabilitating the original jetty structures within their existing footprint would comply with NEPA directives, and provide critical information that may reduce long-term costs and improve jetty life and efficacy.
Recommendations for Resolution:
1. Assess, and validate or reject, the technical basis for the initial jetty design, length, and orientation using appropriate physical coastal process models. 2. Assess structural efficacy and cost of alternatives which are not constrained by the existing footprint. 3. Develop modeling efforts for hydrodynamic models and/or sediment transport models that would provide insights into the following areas: a. Thorough analysis of the existing jetty structures focusing on why some areas have survived without repair and others have needed repeated repairs b. Examination of why Jetty A had such a large O&M cost relative to predictions. c. Addition of subsurface berms potentially created through the beneficial use of project dredged material that may reduce wave impact and subsequently reduce wave overtopping and toe scour.

USACE Final Evaluator Response (#9)
NON-CONCUR The alternatives evaluated do meet the requirements as specified in 1502.14 of NEPA since as stated in 1502.13 the alternatives to be selected and evaluated by the Agency are bounded

by the Purpose and Need Statement for the project. As stated in the Purpose Statement for the project: "The purpose of the proposed action is to perform modifications and repairs to the North and South jetties and Jetty A at the MCR that would strengthen the jetty structures, extend their functional life, and maintain deep-draft navigation." Consequently, we are limited to alternatives that meet these needs.

Major Rehabilitation guidance recommends that the alternative plans developed address alternative maintenance options and re-construction alternatives dealing with the present configuration of the infrastructure. We looked at incremental and graduated improvements through cross sections that extend off of the footprint and supplementary engineering features that locally extend off of the footprint. Based on the magnitude of the environmental and physical processes at this project and the cost of implementation, other forms of infrastructure that do not utilize/maximize the existing structure and footprint are not feasible. Some basic cost analysis comparisons can be used to demonstrate this. Reorienting the jetties or constructing an alternative form of structure off of the footprint would be expected to have significant cost and environmental consequences. In addition, potential negative consequences to the surrounding underwater shoals would be expected.

The alternatives proposed do not maintain the entire 1895 (full authorized) jetty length for any of the jetties. The hydrodynamic modeling results and reasoning for this is presented in the report.

Pursuant to Major Rehabilitation study guidance, the alternatives were formulated to maximize stability of the existing shoals, minimize induced scour, perform in an extreme loading environment, and minimize construction and future repair costs. Other more rigid structures have more vulnerability as well as potential negative consequences on the foundation shoals. This inlet is too energetic and the morphology is too dynamic (vulnerable) to changes in the flow field to make weirs and sediment basins viable primary alternatives at this location. Measures taken to improve the sediment deposition environment include stabilizing the jetty head locations and the addition of spur groins as well as North Jetty backshore improvement.

1. **NOT ADOPT** The purpose of a Major Rehabilitation study is not to re-justify the original design and layout of the project. Documentation can be identified and provided that illustrates how the project layout was incrementally improved over time to meet its intended navigation purpose and how that purpose is still being served now by the present jetty configuration.
2. **NOT ADOPT** Alternatives are included which extend beyond the existing footprint where merited by the loading environment.
3. **NOT ADOPT** The hydrodynamic modeling conducted throughout this study has provided sufficient and relevant information regarding the present project pertinent to the evaluation of reasonable maintenance alternatives. Historical analysis of jetty repair magnitude and location has been performed and will be further annotated for clarity. Jetty A incurred higher O&M costs at least in part due to the utilization of under-sized but readily-available repair materials. Beneficial use of dredged material in order to feed the underwater sand shoals is being pursued under a parallel effort. In addition, this type of action is subject to regulatory constraints and cannot be relied upon to stabilize the rubblemound jetties over the long term.

Panel Final BackCheck Response (#9)
Concur. The Panel understands more clearly the limitation of the project description and concurs with the USACE.

Literature Cited:

Seaburgh, W. C. (2002). Weir Jetties at Coastal Inlets: Part 1, Functional Design Considerations. U.S. Army Corps of Engineers, ERDC/CHL CHETN-IV-53. December.

Comment (#10):
A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
Basis for Comment:
The extent of structure failure or partial failure is well documented and the repairs made to the structure are well documented, as shown in Figures 1-12, 1-15, and 1-16. These figures, however, do not distinguish between areas repaired and areas that are substandard but have not failed and so were not actually repaired. Failure analyses for the groin tips and the runnel formation weakening Jetty A (p. 3-5) are presented, but the report does not include a general failure analysis. A failure analysis would be helpful in determining why one section of jetty failed/degraded whereas another remained intact. This information is needed to derive alternatives that resist both degradation and failure, and result in an informed design of jetty repairs. Maintenance histories (Figures 1-21 through 1-23) show that actual O&M costs have trended significantly above and below the expected O&M costs, based on annual expenditures equivalent to 0.7% of the initial construction costs. Specific causes of actual O&M costs being higher or lower than the assumed 0.7% annual average cost have not been analyzed but can be presumed to be directly related to full or partial failure of portions of the structures. Knowledge of the specific causes of failure combined with the cost of constructing a jetty resistant to these causes taken in consideration of maintaining a jetty less resistant to these causes may be useful in determining or presenting the most cost effective alternative design. A specific presentation of individual jetty failure events would serve to bolster the alternative selection process and the projections of future maintenance costs.
Significance – Medium:
Uncertainty regarding the specific causes of failure and their relationship to trends of past O&M costs creates a functional uncertainty in the corrective measures in the alternatives for repair and rehabilitation.
Recommendations for Resolution:
1. Include an analysis of the causes of failure for each repair event (e.g., Figure 1-15) even if only a statement of "storm intensity" in order to provide assurance that the repairs address the actual causes of previous jetty failures. 2. Relate construction costs of more resistant designs to repair costs of less resistant designs for each causal condition of failure and the associated selected alternative.
USACE Final Evaluator Response (#10)
NON-CONCUR The below excerpt from Appendix A2 summarizes some of the information that is requested above for Jetty A. Other similar information has been included for the North Jetty and the South Jetty "To date, the average annual rate of maintenance actually expended on the Jetty "A" has been 2% of structure's initial construction cost. This is considerably higher than a value of 0.7%, which is the expected value for MCR jetties. A high level of maintenance was expended on jetty "A" soon after construction, to address extreme foundation scour and low resiliency of initial jetty construction. Initial repair actions implemented for Jetty "A" during the 1940s-50s also produced a low level of resilience, requiring rehabilitation of the jetty during 1961-1962 following a breach event during the 1950's."

Different areas of the jetties were constructed to a variety of templates and then maintained in various levels of robustness. Degradation of the jetty reaches were a function of how they were originally constructed, how they were repaired, and how environmental conditions changed around them. Extensive effort was expended in the analysis of the wave climate and projected future changes to the loading environment. We have identified where scour has occurred and where wave action has controlled the degradation of the jetty cross section. Alternatives have been proposed to address these concerns including stone size, side slope, toe berm size, etc. Please see the attached chart showing historical repairs by location and cost in 2010 dollars. 1. ADOPT NOW. . A summary table will be provided which pulls together in one location the repair history, design attributes and ongoing deficiencies leading up to the repair for each area of each jetty. 2. ADOPT NOW. This has already been included in the report, however, we will adjust its location and content to ensure that it is covered adequately.
Panel Final BackCheck Response (#10)
Concur.

Comment (#11):
Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.
Basis for Comment:
The issue of climate change, sea level rise, and increased wave action is important to consider in the evaluation of long-term projects (USACE, 2009). There is no discussion in the main report of sea level rise and its impact on this project over the 50+ year project timeline. There is a limited discussion of climate change in Appendix D (p. 5), where the conclusion is that since the projected historical trend of sea level at the project site is estimated to be -0.05 feet in 50 years, sea level rise is not projected to be a significant climate change factor at the project site. Appendix D states the "comprehensive analysis of historical storm events is expected to adequately capture the present deep water contribution of potential wave height variation for this project site. The above approach forms the basis for estimating the potential changes in wave climate that could affect the MCR jetty system." However, this discussion on wave height trends is not compelling. The main report states (p. 1-6), "As the tidal shoals continue to recede (erode), the MCR jetties will be exposed to larger waves and more vigorous currents. To make matters worse, the regional wave climate along the Northwest Pacific Coast has become more severe in the last 10 years. The offshore 100-year wave height has been revised from 41 to 55 feet." (see also Appendix D). The main report states (p. 3-42), "The limit of cross-section resiliency is reached for jetties when the core stone becomes exposed to wave attack." Therefore, this issue may affect jetty erosion and a larger range of wave heights should be included in both the SRB and STWAVE model scenarios. Wave overtopping is central to the environment deteriorating the existing jetties. As the planning horizon of this project is 50+ years, it seems that a discussion would be useful of sea level rise and modeling potential wave heights and the wave overtopping impacts on the jetties given different rates of recession under a wider range of wave heights. Jetty height and crest elevation are variables that should be modeled given the potential larger wave heights possible under sea level rise. Although the selection of the recommended plan may not change, long-term maintenance costs may be affected, therefore consideration is warranted. Appendix B states that transient internal hydraulic effects of wave impact may be the most important parameter in the stability of the jetties. However, it is the least certain of all of the parameters. Internal hydraulic pressures in jetties have not been measured. Given this, it seems especially important to consider more extreme wave heights beyond the wave height analyzed, with respect to sea level rise and potential increasing wave height.
Significance – Medium:
The discussion of potential impacts of sea level rise and increased wave action on jetty structures is critical to understanding the potential impacts to the project and in designing a project with lower long-term maintenance costs.

Recommendations for Resolution:
1. Add a separate section to the Major Rehabilitation Evaluation Report that examines climate change, sea level rise, potential wave height changes, and resulting wave overtopping impacts on the jetties given different rates of recession under different model scenarios.
USACE Final Evaluator Response (#11)
NON-CONCUR Discussion of potential sea level rise as well as its impact on potential future loading on the MCR jetties has been included in Appendices A1 and A2. Portions of that discussion can be moved to the Main Report for completeness. All of the factors discussed above have been incorporated into the wave height loading for the structures. An extremal analysis has been performed utilizing the period of record for the Columbia River NDBC buoy producing the expected long-term estimates of extremes at the project area. This estimate compares well with the recent analysis conducted by Ruggiero for the Oregon coast wave climate. An incremental increase in wave height has also been included to reflect the potential for an upward trend in storm intensity. The project event tree simulation includes a function that gradually increases the depth-limited wave height incident to the structure as the scour increases and the water depth at the structure increases. The potential for sea level rise was incorporated in the project event tree simulation and life cycle analysis of the project. As directed by USACE (2009), three separate potential sea level curves were estimated placing the potential sea level change at the project site over the 50 year planning horizon somewhere between -0.05 ft to +1.6 ft. Each life cycle run for the project utilized one of the sea level change curves in order to factor in that potential change in project loading and its impact on maintenance requirements and effectiveness. With the slightly greater water level at the project site during these realizations, the incident wave height was also adjusted accordingly. So the future case scenarios incorporate both a higher water level as well as the impact of wave height. **1. ADOPT NOW** by moving the sea level rise section of the report to the Main report for better clarity. In the analysis, the waves are currently estimated at three different potential water levels. The relative mildness of sea level change at the project site makes the inclusion of sea level change in the total loading environment less of a driving factor in a long-term maintenance strategy. In addition, due to the uncertainty of future sea level rise scenarios, the most likely approach for very large rubblemound structures for future maintenance would be to develop an adaptable maintenance strategy that could be modified as the gradual change is observed.
Panel Final BackCheck Response (#11)
Concur.

Literature Cited:

USACE (2009). Water Resource Policies and Authorities Incorporating Sea-Level Change Considerations in Civil Works Programs. Department of the Army, U.S. Army Corps of Engineers, Washington, D.C. Engineer Pamphlet EC 1165-2-211. 1 July.

Comment (#12):
Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.
Basis for Comment:
A detailed construction cost estimate summary should be provided for the recommended plan, otherwise the basis for the total cost values provided in Section 6.5.9 cannot be reviewed and assessed to determine if they are realistic and complete. The cost estimate information provided in the main report (Section 6.0) and in Appendix E is not sufficient to support the recommended plan: • Table 6-3 provides a detailed summary of stone volumes for each jetty by construction year, but there is no correlation with construction costs or to the cost estimates provided in Section 6.5.9 or Appendix E. • Specific cost estimating details are provided in Sections 6.5.7 and 6.5.8, but the assumptions and criteria defining the basis for the cost estimates do not include any summary unit costs for the individual work items. • Unit costs are provided in Tables A2-9 to A2-11 but pertain to the SRB modeling effort. There is no discussion regarding how they relate to the final project costs presented in Section 6.5.9. • Appendix E includes budget summary costs for construction, planning/engineering, construction management, and land acquisition. Detailed cost estimates for the Civil Works construction budget numbers are not provided and the basis for the costs cannot be reviewed or verified. • Costs for the barge offloading and material re-handling area facility installation and maintenance are not described, yet they could be a large direct and indirect cost to the project based on wave exposure (for type and size of barge offload facility structures). The structural requirements (and corresponding construction costs) for an exposed vessel berth will be many orders of magnitude larger than the same berth in protected waters. Stone delivery cost represents a very large percentage of the total cost. Ensuring a cost feasible method of delivery to the jetty structures is critical for development of an accurate cost estimate.
Significance – Medium:
Detailed construction cost estimates need to be provided in order for the cost analysis to be complete and verifiable.
Recommendations for Resolution:
1. Provide a detailed cost breakdown by work item for the Civil Works project item, Breakwater & Seawalls. Provide detailed cost estimates for each major element of work (e.g., mobilization, stone supply and install, site preparation, material re-handling facility installation, maintenance of re-handling facilities, etc.). Give details regarding work item quantity, unit costs, contingency, and escalation. 2. Provide a detailed cost summary within Appendix E, and an additional detailed description of the basis for the costs estimates in Section 6. 3. Conduct an additional investigation of re-handling facility requirements to adequately determine the costs for facility installation and maintenance.

USACE Final Evaluator Response (#12)
CONCUR 1. **Adopt Now**: Appendix E was not included in the report and includes an MII summary report, narrative, schedule, cost and schedule risk analysis, and TPCS. 2. **Adopt Now**: The basis for the cost estimate is noted in the narrative section of Appendix-E. 3. **Adopt Later**: Reference the MII summary report in Appendix E. The estimate assumes construction of an off loading facility at the beginning of the construction season and removal at project closeout. Yearly roadway, ramp, dredging, and storage area maintenance are also included. Jetty crest haul road and turnout re-construction materials are included in the yearly cost and labor and equipment is assumed in the jetty stone production rate of 100T/Hr. Costs and contingency have been assumed for the MMR phase and will be further refined in the DDR phase of the project.
Panel Final BackCheck Response (#12)
Concur. The Panel was not able to answer Charge Questions which were "Comment on the overall adequacy and reasonableness of the detailed cost estimates" and "Are the Cost Estimates Complete and Consistent?" since detailed cost estimates were not provided. It is our understanding a separate Corps cost review processes will be conducted during the next phase of the project which will answer these questions.

Comment (#13):

Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.

Basis for Comment:

Appendix D and main report (pp. 5-17—5-20) list potential in-water, wetland, and upland impacts. These impacts should be addressed in the mitigation plan. The mitigation plans currently address these three general categories, but do not provide mitigation for potential impacts to specific species, upland habitats and water quality. The mitigation plans are incomplete because the final wetland delineation for the project has not been conducted, and the impact to wetlands and upland habitat is uncertain and therefore not quantified. A vegetation restoration plan is needed to address potential impacts to upland habitats, especially the rare and vulnerable species discussed below. At a minimum, the mitigation plan should state that these plans will be prepared prior to construction activities. Although the extent of the upland impact on this habitat is uncertain, a replanting contingency plan and a clear plan for avoidance are important to include in the mitigation plan. Similarly, potential water quality impacts from spills should be addressed in the mitigation plan with a statement about the spill prevention plan, as discussed below.

Section 5.1 (Environmental Effects) of the main report provides details on biological resources, but is missing a vegetation section. Appendix D contains two reports including the Wetland and Waters of the U.S. Delineation Report and The Plant Communities Investigation Report, April 2007, which provides details on the vegetation communities; however, this information is not presented in the main report and therefore the main report lacks a definition of the plant species of concern within the project area. The revised EA states (p. 6) that at least three of these vegetative communities (shorepine-slough sedge, shorepine-Douglas fir, and coast willow-slough sedge) "have been ranked globally and by the State for their rarity and vulnerability to extinction and should be protected from impacts." This information on sensitive species should be integrated into Section 5.1. Furthermore, potential land construction activities as shown on Figure 5-1 of the main report may affect plant communities, including sensitive habitats, warranting a discussion of existing vegetation in the project area. Vegetation impacts that may result from construction are not detailed in the document, and just briefly mentioned in regards to the South Jetty. Mitigation plans should include specific protective measures to avoid potential impacts to these rare and vulnerable species.

In general, the main report discusses Endangered Species Act (ESA) species, but does not provide detailed data on specific animal or plant populations. In 2005, critical habitat was designated for all Columbia River steelhead and Columbia River salmon evolutionarily significant units (ESU), with the exception of lower Columbia River coho salmon ESU. Although a wide range of potential impacts are discussed (p. 5-16), ranging from loss of habitat to an increase in perching and in-water habitat for predators that prey on listed species, the mitigation section of the Major Rehabilitation Evaluation Report does not address these impacts. The main report concludes (pp. 5-19 – 5-20) that there will be overall benefits to these species from this project. Additional details would be helpful to ensure that these species suffer no impacts. The Panel realizes that as a specific mitigation plan is developed, this may likely be incorporated.

Water quality may also be affected over the project duration due to the large volume of container ships, construction dredges, barges, and cruise ships operating in the area, sometimes in adverse extreme weather conditions. For example, there may be a loss of hydraulic fluid or oil spills (p. 3-70). In the discussion of the mitigation plan in Section 5.4 (p. 5-17), the increased risk of pollutant release and spill potential is raised as a potential impact on ecosystem function. A sentence earlier in the document (p. 5-2) states that the Contractor "will provide a spill prevention plan to include measures to minimize the potential for spills and to respond quickly should spills occur." This sentence belongs in Section 5.4 of the main report as well.

Any history of spills in the Mouth of Columbia River area should also be reported in the document. Providing these details will enable a more thorough analysis of environmental impacts and enable additional protective actions to be implemented.

Significance – Medium:

Additional biological resources data and potential impacts to sensitive species, upland communities and water quality is needed to adequately protect the environment and define the mitigation needed to reduce these impacts to less than significant.

Recommendations for Resolution:

1. Incorporate additional information into Section 5 of the report:
   a. A vegetation section defining the sensitive species within project area.
   b. A statement to ensure that stockpiling activities shown in Figures 5.1 – 5.3 of the main report minimize the land impacts to sensitive habitats and wetlands. State whether a survey will be conducted prior to construction activities with sensitive habitats flagged to ensure avoidance.
   c. Provide detailed data on specific animal or plant populations that are listed species
   d. Specific text in the mitigation section for potential impacts to steelhead and salmon.
2. Add the wording from p. 5-2 into Section 5.4 of the mitigation plan regarding the contractor's requirement to prepare a spill prevention plan to address potential water quality impacts. Document any known history of spills in the area.

USACE Final Evaluator Response (#13)

CONCUR

Chapter 5 of the Major Rehabilitation Report has been updated and supplemented with the requested information. Analyses of effects to listed species, water quality, and socio-economic resources have been completed in the associated Biological Assessments, draft Final EA, and the draft 404(b)(1) documents. There is also currently a wetland delineation under completion, and results will be incorporated into the EA, 404(b) (1) evaluation, and final designs, as appropriate.

1. **Incorporate additional information into Section 5 of the report:**
   a. **ADOPT NOW:** A vegetation section (Section 5.1.7) has been added to Section 5 of the main report. This new section describes the sensitive habitats and wetlands in the project area. It also includes an illustration of these areas for the Clatsop Spit.

   b. **ADOPT NOW:** The following text has been added at the end of the new Section 5.1.7: "Construction staging/storage and rock stockpile areas shown in Figures 5-1 to 5-4 were sited to minimize land impacts to sensitive habitats and wetlands as much as possible. Wetland delineations are underway and sensitive habitats will be flagged prior to construction activities to ensure their avoidance." Additional figures have been added to illustrate stockpile locations relative to higher-value habitat.

c. **ADOPT NOW:** Detailed information has been added to Section 5 about listed animal and plant species with the potential to be in the project area. Specifically, Section 5.1.2 has been expanded for anadromous salmonids, green sturgeon, eulachon, and bull trout; Section 5.1.5 has been expanded for marine mammals and sea turtles; Section 5.1.6 has been expanded for terrestrial wildlife and seabirds; and new Section 5.1.7 (Vegetation) includes listed plant species.

d. **ADOPT NOW:** Additional text has been added early in Section 5.4 to discuss that the Corps has incorporated habitat improvement features into the proposed action to assist with the recovery of ESA-listed salmonid habitats and ecosystem functions and processes. These actions are not proposed to directly mitigate or compensate for any project-related impacts to ESA-listed salmonids. The habitat improvement features of the overall ecosystem restoration action are proposed as conservation measures under Section 7(a)(1) of the ESA. These actions are the Corps' affirmative commitment to fulfill responsibility to assist with conservation and recovery of ESA-listed salmonids. In addition, a table with possible wetland mitigation and habitat improvement features has been added. The wetland mitigation totals will be updated when current delineations are completed.

2. **ADOPT NOW:** The statement, "the contractor will provide a spill prevention plan to include measures to minimize the potential for spills and to respond quickly should spills occur," has been added to Section 5.4 (mitigation plan), as requested. Also, the environmental staff is attempting to determine the history of spills in the MCR area and what information is available will be incorporated into this report as well as the EA and 404(b) (1) evaluation.

Panel Final BackCheck Response (#13)

Concur.

Comment (#14):

Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.

Basis for Comment:

The Major Rehabilitation Evaluation Report does not provide detail on the impact of the project construction activities on recreational use, an issue that came up in public comment letters (main report, Section 5.4). The last sentence in Section 5.3 states that there will be no significant impacts on recreation.

Appendix C states that there is a growing cruise ship industry and it is unclear how construction activities will affect passenger cruise ship access. On p. C-3 it states that 5/7 day cruise ship tours carry 15,000 passengers annually, and thousands of tour boat passengers take day trips and dinner cruises. These activities generate about $15 to $20 million in revenue annually for local economies. Public access during construction may be an issue. In addition, other recreational uses of the area may be reduced, such as kayaking and hiking.

These impacts should be defined, rather than concluding that no recreational or economic impacts to tourism are expected. Omitting this issue may lead to unforeseen consequences for the cruise ship and tourism industries.

Significance – Medium:

Recreational impacts are not adequately presented in the report and subsequently, no mitigation is identified for this potential impact.

Recommendations for Resolution:

1. Add a discussion of the cruise ship industry and other recreational uses at the project site.
2. Examine potential impacts on cruise ships and other recreational activities that may result from the dredging operations and jetty repair operations.
3. Provide potential mitigation options to reduce recreational impacts to less than significant levels.
4. Make a distinction between recreational impacts during construction and after construction.

USACE Final Evaluator Response (#14)

CONCUR

The Major Rehab Report will be updated and clarified with the information requested. Though cruise ships utilize the navigation channel, they will not be docking anywhere near the bulk of the jetty work, and instead debark upriver in Astoria. Recreational impacts will be included in the draft final EA.

1. **ADOPT NOW:** Section 5.1.9 has been revised to better reflect the recreational uses in the project area, including cruise ship passage through the MCR.
2. **ADOPT NOW:** Section 5.19 has been revised to discuss the potential impacts to recreational activities and cruise ships during construction of the proposed action.
3. **NOT ADOPT:** Recreational impacts are not expected to be significant enough to warrant mitigation.
4. **ADOPT NOW:** Section 5.19 has been revised to better discuss the recreational impacts during and after construction of the proposed action.

Panel Final BackCheck Response (#14)
Concur.

Comment (#15):
There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.
Basis for Comment:
Contract-provided barge offloading facilities for the South and North Jetties are described in Sections 6.3.3 and 6.3.4 and shown in Figures 5-1 and 5-3 of the main report. Based on the information presented, it is not clear that these sites have been adequately investigated and are suited for their intended use. The barge offloading and material re-handling facilities at these outer exposed locations should be further investigated to ensure they are economically and operationally feasible. The proposed facilities are referred to as "temporary," but this is questionable if they will be in place for 20 years. The life-cycle costs of the docks and other structures are not trivial and do not seem adequately analyzed. The largest cost and a substantial risk for the recommended plan involves the purchase, transportation, delivery, and offloading of the stone in a very difficult environment over a relatively long time. The USACE-provided sites also need to be operationally feasible in order to use a permitted method of delivering material to the site. Providing contractors with better information on the limitations and usability of these sites at the time of bidding could result in substantial cost savings. There is no discussion in the report of any engineering work performed to evaluate the feasibility of installing structures at these exposed locations, nor any mention of operational feasibility for the size of vessels and wave climate for the periods of construction. These locations are subject to wave heights of more than 15 feet, which will impose very large wave impact loads on fixed structures (dolphins and sheet pile walls), resulting in high risk and cost facilities. USACE intends to permit these sites and provide them to the contractor as the primary point of access. This establishes a certain level of perceived usability to bidders. If they are later determined not to be feasible (i.e., during contract bidding or during construction), it would result in substantial cost and schedule changes. Use of the re-handling facilities will be limited to a "summer" work period (April to October). There is no analysis of sedimentation rate in the report to verify whether the floatation channels will remain open for the summer construction work period. Maintenance dredging estimates for barge offloading facilities are provided in Table 6-1, but it is not clear for what time period (annually or total over the entire duration of the project). Jetty A is listed at 80,000 cubic yards for maintenance dredging. Other options, such as dredging within the Ilwaco channel to the trunk end of Jetty A and developing an offloading facility adjacent to the staging area could be considered.
Significance – Medium:
Insufficient information on the limitations and usability of the offloading and re-handling sites could affect construction cost estimates and project schedule due to operational and physical environment constraints.
Recommendations for Resolution:
1. Conduct a feasibility level engineering analysis and design for the contract-provided offloading and rehandling sites to ensure that selected sites and facilities are feasible and provide reliable estimates of construction cost. The feasibility evaluation should at a minimum include the following: a. Evaluate feasibility of constructing pile supported structures within an extreme hydrodynamic environment. This includes wave/current loads on moored vessels

during the construction period and wave/current loads berth structures during extreme winter conditions.

   b. Evaluate downtime of barges at the proposed sites relative to the wave and current climate during the proposed construction work period.
   c. Refine the type of structure that is feasible for these locations for inclusion into project permits and cost estimates.

2. Evaluate the need for alternative barge offloading and material re-handling site locations based on the results of the feasibility analysis.
3. Evaluate design concepts for permanent barge/dock facilities, possibly incorporated into the inside face of the jetties near their root.
4. Develop environmental data specific to the proposed offloading site locations for bidders/contractors to use in developing their estimates of downtime and infrastructure requirements at USACE provided rehandling sites. Extreme event offshore wave data and jetty structure design criteria will not be sufficient for contractors to use in evaluating short-term operational and design requirements.

USACE Final Evaluator Response (#15)

CONCUR

Further analyses for evaluation of barge-offloading facilities will be conducted as needed during the final design and plans & specification stage of study. The current estimate is based on historical repair activities at the project, knowledge of the wave environment during the normal construction season, and experience at similarly exposed locations. Site specific information will be provided to the contractor for their use in evaluating their equipment and capabilities with respect to the site conditions. MCACES estimates already include a reasonable estimate for offloading site construction, dredging, and maintenance. Allowances have been included for additional dredging during the construction season and between construction seasons.

1. **ADOPT in FUTURE**: The design of the barge offloading and material re-handling facility will be conducted during the DDR phase of the project. General coordinated locations have been graphically noted in figure 5-1 to 5-4 and conservative costs have been included in the cost estimate.
   a. A site design for the facility described will be performed during the DDR for establishing a fair and reasonable cost for the government cost estimates. Design criteria will be established during the DDR phase but specific designs and implementation will be up to the contractor
   b. Usability of the site will be examined.
   c. A feasibility study will be conducted for inclusion in project permits and cost estimates.
2. **ADOPT in FUTURE**: Barge offloading and material re-handling site locations will be addressed in the DDR phase.
3. **NOT ADOPT**: Permanent barge/dock facilities were not considered due to environmental and hydraulic considerations.
4. **ADOPT in FUTURE:** Engineering and environmental data specific to the offloading site locations will be developed in the DDR phase.

Panel Final BackCheck Response (#15)

Concur.

With respect to Recommendations #1 and #2, the Panel agrees detailed design should be done in the next phase of the project but some details associated with these material re-handling sites should be further investigated during this phase and not deferred to the future. The Mouth of the

Columbia River is an extremely dangerous area for vessel navigation and mooring. If the barge facilities are located in conditions later determined by Contractors to not be safe or to have significant operational downtime, it will greatly affect the projects cost and schedule. The panel assumes that the Corps has adequately investigated the barge offloading facilities with sufficient adequacy that it was determined that they are safe and usable for the purpose of delivering stone materials onto the jetty for the proposed rehabilitation work.

With respect to Recommendation #3, the Panel recognizes the material re-handling facilities are temporary but USACE has stated in their response to Panel comments the barge terminal will be installed at the start of the project and removed at the conclusion. If the project duration is 2012 to 2030 (18 years), the facility should be treated more like a semi-permanent facility (remains in place for entire calendar year versus temporary inferring removal each year) for the purpose of structural engineering design and determination of feasibility of construction and operations. This has very big implications on the structural design since it needs to withstand large winter storm wave conditions for a design criteria associated with a longer service life than most temporary construction facilities. The panel assumes that the Corps has adequately investigated the barge offloading facilities with sufficient adequacy that it was determined that they are safe and usable for the purpose of delivering stone materials onto the jetty for the proposed rehabilitation work.

Comment (#16):
The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.

Basis for Comment:

Dredging is a substantial component of this project and has been historically, yet there is no clear discussion of the role of dredging in the Major Rehabilitation Evaluation Report. Typical annual dredging rates are not presented in the document itself, although Appendix A1 (p. A1-3) states, "Each year, the Portland District dredges 3 to 5 million cubic yards (MCY) of sand at MCR to maintain the 5-mile long deep draft navigation channel." It is unclear if the Portland District dredging is conducted exclusively at MOCR. Analysis of the project area maintenance dredging requirements – past, present, and future – have not been presented.

Controlling dredging costs is critical to this project. The EPA publishes a report annually analyzing dredged sediment disposal in the nation. About 4 million cubic yards is dredged at the MCR every year at an annual cost of about $10 million. The fact that maintenance dredging volumes in the project area have not increased (no clear trend) since 1956, despite ongoing jetty tip recession, raises the question of how much jetty is now needed to maintain the MCR navigation channel. However, the main report does not discuss details of the maintenance dredging. Appendix B states the geological history includes 225 million cubic yards of dredging from the MCR navigation channel since 1956. The volumes, history, and fate of these dredged sediment volumes should be described in the main report and are missing from the analysis. The fact that most of this sediment was dumped far offshore and lost to the nearshore may have something to do with the erosion experienced in the area. This large quantity of dredged material warrants discussion and additional consideration of strategies to reduce this volume.

The discussion of emergency dredging is also lacking in the main report. The historical downtime for dredging at the dock and jetty repair work during the time period of October to March (peak period for large waves) is not provided. Page 3-70 states, "Given the winter wave conditions that the dredges would be performing in, it is highly likely that damage would occur to the drag arm of the dredge while working." Page A2-65 states that within the SRB model "there is a 0.3 probability that one dredge will lose a drag-arm while performing dredging during winter or a 0.7 probability that one dredge would realize equipment damage," thereby increasing dredging costs. Several places reference the difficulty of dredging in the winter. Conditions may preclude effective dredge use, or the dredge may break and become inoperable, suggesting dredging may be postponed until summer. In terms of dredge operation, p. 1-48 gives the operational limitations of hopper dredges, and admits that operating a hopper dredge at the MRC during winter months has not yet been attempted. Therefore, the inadequate demonstration of equipment effectiveness, lack of documentation of the basis of dredge damage probabilities, and lack of historic utilization increases the risk associated with estimating costs associated with emergency dredging.

The document states on p.1-50 that the rate of shoaling within the MCR channel would not be high enough to require emergency dredging; therefore, the increased shoaling volume could be dredged the following summer and would not be considered emergency dredging. The document never presents operational triggers for when emergency dredging would occur.

The main report indicates that there are four dredges capable of working in winter (p. 3-111), but these dredges are not mentioned earlier, when it was presented that only one or two dredges are available in the short term. A discussion of emergency dredging history, success in other areas, and a description of the equipment available is warranted.

The analysis considers long-term O&M costs of dredging, but does not explain the criteria used in the calculation estimates.

There is no mention of any historic environmental impacts from the dredge operations, such as spills. If spills have occurred, data should be presented.

Significance – Medium:

Additional information on dredging may enable better analysis and lead to a long-term reduction in dredging costs and the development of a contingency plan to successfully avoid navigation impacts.

Recommendations for Resolution:

1. Develop a paragraph on dredging in the main report that specifies clearly what the maintenance dredging program has been, rates, and frequencies, and if they are scheduled or "as needed." Present all the historic maintenance costs, schedules, and frequencies.
2. Provide a detailed history of emergency dredging with success and failures and costs.
3. Add information to specify what rate of shoaling requires emergency dredging compared to scheduling maintenance dredging activities.
4. Present the criteria used in the calculations of dredging O&M costs.
5. Provide any information on historic spills related to dredging operations.

USACE Final Evaluator Response (#16)

CONCUR

Historical dredging efforts can be explained in more detail for the main report. Our objective under this study is to try to avoid an increase in dredging above the current condition. Stabilization of the heads of the jetties should limit changes in the dredging impacts. The model simulates in the without project condition, the continued recession of the jetty heads and the resultant impact on dredging requirements within the MCR.

Holding the present jetty head at its current position will reduce the amount of future dredging compared to letting the jetty heads recede back . Our present O&M dredging is reflective of many processes operating within the inlet; transport of sediment from the estuary, transport of sediment from the ocean, re-distribution of sediment within the sand shoals in the inlet.

We know that sediment is transported into the inlet by migrating past the jetty heads as the heads of the jetties recede landward. This method of sediment transport and subsequent shoaling within the channel persists. The objective of limiting the rate of landward recession of the jetty head is two-fold; it maintains the morphology along the jetty which protects the jetty itself and reduces the rate of channel shoaling associated with jetty head recession. This study was an incremental analysis of channel shoaling related to jetty head stabilization or recession. We will continue to see the same rate of channel shoaling as we have in the past if we do nothing, however, if the jetty head recedes faster, more shoaling will be exhibited. This is a reasonable estimate and not overly conservative.

Changes to the inlet have occurred since 1956. We have also deepened the channel during that time frame. The occurrence of the same amount of dredging is because the jetties have been receding since 1956. Since the last channel deepening , the volumes have been variable but relatively consistent including the effect of jetty head recession. If we prevent jetty head recession, the component of shoaling associated with jetty head recession will be reduced, decreasing the long-term average of sediment entering the channel.

We did not look at all of the dredging history details because we believe the recent past to be the baseline condition from 1986 forward. There are various levels of maintenance and incremental deepening activities between 1956 and 1986. Our potential impact on this process through the jetty maintenance proposals is intended to stabilize current condition of the jetties and thereby reduce over the long-term the amount of shoaling associated with jetty degradation.

Jetty Length options were discussed at the beginning of the study. The decision was made that the rehabilitation and repair plans would stabilize the jetty head at the most cost-effective location in order to not negatively impact the stability of the surrounding shoals, hydrodynamic and environmental processes, and navigation at the MCR entrance.

Over the time period of 1956 to 1996, more than half of the dredged material was placed in the nearshore zone, water depth of 60 ft or less. All of this information can be referenced and explained based on previous studies. The inlet has been eroding because it was thrown out of balance at the time of navigation inlet improvement. Our goal is to manage the rate of morphology change by implementing regional sediment management (RSM) so that we can sustain navigation through the inlet through jetty maintenance and shoal and shoreline management.

Equipment abilities and emergency response times at the MCR during winter conditions were determined to be feasible, but at a reduced efficiency rate during winter conditions. This situation and a reasonable response was discussed with the Operations office in the Portland District. Appropriate response times and resultant equipment, mobilization and delay costs were included in the model and have been documented in tables located in appendix A2.

For the South Jetty situation and in some cases also for the North Jetty if the shoaling volume into the inlet is less than 250,000 cy, dredging would be expected to be performed the following summer. This can be clarified in sections of the main report

Descriptions of dredging capabilities and availability can be improved in the main report. The assumption is that the government dredge would be available depending on repair schedule and that a second contract dredge could also be mobilized but with a longer deployment time period.

1. **ADOPT NOW**. This information will be provided in the main report (with assistance from Operations).
2. **ADOPT in FUTURE**. Operations can assist in further defining the emergency dredging constraints, failures and expected costs.
3. **ADOPT NOW.** Bring discussion from Appendix A2 up to main report.
4. **ADOPT NOW**. Bring discussion from Appendix A2 up to main report.
5. **ADOPT NOW**. Information will be investigated and provided (with assistance from operations)

Panel Final BackCheck Response (#16)

Concur.

Comment (#17):
The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
Basis for Comment:
Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition. A condition assessment of each jetty structure should be conducted through a combination of visual inspection (stone size, gradation, slope defects, stone defects, loss of armor stone, core exposure, etc.) and evaluation and comparison of historical electronic surveying results (single beam, multi-beam, or side scan sonar data). These elements will provide the basis for determining the present condition, assess risk of current condition to failure, and help classify structure along various reaches of each jetty. These data would enable better assessment of vulnerabilities, analyzing why some areas in the jetty have maintained without repair and other areas have needed multiple repairs. A better understanding of these dynamics may reduce O&M costs over the long term. Rubble-mound structures have a tolerance for deterioration before suffering catastrophic failure. A thorough understanding of current and historical structure condition is critical to developing an estimate of the mechanisms causing failure, establishing the timeframe for catastrophic failure, and conducting maintenance/repair work. The SRB model evaluation of alternatives using the base condition depends upon an adequate understanding of current jetty conditions and corresponding impact on estimated future repair and maintenance. The current SRB analysis is based on a “hindcasting” of jetty performance relative to historical performance, but without consideration of the details of condition and causes of failure. The current and historical condition relative to structural and functional rating should be conducted following USACE procedures (USACE, 1998) to establish the baseline conditions for the SRB model analysis. Evaluation of stone source and quality relative to length of service on the structure should be conducted as part of the jetty condition assessment.
Significance – Medium:
A detailed description of the current jetty structure as part of a condition assessment is necessary to understand the accuracy of the SRB model.
Recommendations for Resolution:
1. Conduct a detailed condition assessment of each jetty structure, including visual inspection and historical survey comparison. 2. Compare historical survey data for the validation of interpreted historical conditions and corresponding perceived modes of failure. Incorporate results into the development of baseline conditions for the SRB model. 3. Use a condition rating system such as that outlined in the USACE Manual REMR-OM-24 (USACE, 1998) for evaluation of current condition. Assess both the structural and functional condition of the structures and incorporate the results into the SRB model analysis. 4. Incorporate the results of the condition assessment into Section 1.4, description of project history. 5. Provide an additional description of existing condition in Section 1.4 and 3.3.2 of the

main report, including the service life of stone sources used for previous repair and maintenance activities.

6. Based on the results of the condition assessment, the relation between the stone sources reviewed (in Appendix B, Section 5) and the corresponding observed service life of that stone should be discussed and incorporated in the SRB analysis.

USACE Final Evaluator Response (#17)

CONCUR

At numerous locations in the report, reference is made to jetty condition, cross section template deficit, vulnerability and damaging modes of jetty reaches. Various tables and plots also provide information. Information provided includes existing crest elevation and crest width, toe elevations on either side of structure, as well as general condition and design concerns for each reach. Environmental loading and project condition changes along both sides of each jetty length were also evaluated to assist in evaluating cross section capacity.

As a requirement of the Major Rehabilitation guidance, stability equations and performance modes are required to be assessed for the structure being analyzed. The 2006 multi-beam and above water structure survey was utilized in providing the existing conditions relevant to the application of the jetty stability equations and the production of structural reliability values for each 100 ft segment of each of the jetties.For each jetty, given the primary design and performance modes, structural reliability was calculated for each 100 ft length of jetty. This information can be provided along the length of each structure. At present this information has been calculated but rather than displayed along the length it has been incorporated in the project event tree simulation. A table will be provided with summarizes this information.

The SRB model execution in hindcast mode includes the original and all subsequent repair cross section parameters per 100 ft of jetty including stone size parameters. Project/structure changes, environmental loading, and damages incurred were all included in assessing cross section capacity.

The condition of the structure (original, repair, existing) are all inputs to the model so that each 100 ft segment can be based on true physical capacity parameters. The causes of failure are typical rubblemound modes of failure (see attachment 2) and are documented in historical cross sections, observed damages on the structures, physical modeling, as well as a good hindcast representation using those standard damage modes. The resiliency and ability for a rubblemound structure to incur some damage and still function is simulated in the model , the mechanism causing failures explained, performance modes identified.

1. **ADOPT NOW.** The latest MCR jetty inspection as well as consolidating existing condition and vulnerability information are already provided in the report. Attachment 1 summarizes locations in the report where information on existing condition and design concerns can be found. Attachments 3 to 5 illustrate the minimum template deficits along each jetty length. Attachments 6 through 9 illustrate the latest MCR inspection report.

2. **ADOPT NOW**. A better summarizing of the hindcast and the existing condition stability and reliability assessments already conducted and provided in the report will be included.

The SRB model execution in hindcast mode includes the original and all subsequent repair cross section parameters per 100 ft of jetty including stone size parameters. Project/structure changes, environmental loading, and damages incurred were all included in assessing cross section

capacity. For the existing condition for each jetty, given the primary design and performance modes, structural reliability was calculated for each 100 ft length of jetty. That information will be better summarized in the final report. 3. **NOT ADOPT**. The condition rating system is intended for use as a preliminary assessment tool that can inform decision-makers when it is feasible to move into a more intensive analytical phase for the project. In the case of the MCR structures, that intensive analytical phase is represented by the Major Rehabilitation life cycle analysis including a complete performance and stability mode analysis per 100 ft of jetty structure for each of the primary jetty structures. 4. **ADOPT NOW.** Adopt by better summarizing and describing the existing condition of the MCR structures. 5. **ADOPT NOW.** Adopt by moving some of the quarry and stone source information from Appendix B into the main report. 6. **NOT ADOPT.** Stone durability has not been found to be an issue for any of the stone sources that have supplied stone in the past to the MCR structures.
Panel Final BackCheck Response (#17)
Concur. Condition assessment should be better described and incorporated into a failure analysis summary. This combined information could be included in a summary table which pulls together in one location the repair history, design attributes and ongoing deficiencies leading up to the repair for each area of each jetty.

Literature Cited:

USACE (1998). Condition and Performance Rating Procedures for Rubble Breakwaters and Jetties. REMR Management Systems—Coastal/Shore Protection System Devices. Technical Report REMR-OM-24, U.S. Army Corps of Engineers, Washington, D.C.

Comment (#18):
The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.
Basis for Comment:
Causes of jetty head scour have not been sufficiently investigated. Tidal shoal and outlet channel geomorphic processes should be further evaluated and analyzed to ensure that proper jetty head repair measures are selected. The mechanisms causing the "scour holes" and undermining of the jetty in the vicinity of the jetty tips (North Jetty and Jetty A) have not been sufficiently analyzed for selection of the jetty head repair measure. Figure A1-32 indicates a progressive erosion of ebb tidal shoals in the vicinity of the North Jetty (between Stations 60 and 90) undermining the south toe of the structure. The report understates the situation when it notes (Appendix A1, p. 28), "If the jetty foundation washes away, jetty reconstruction is problematic." A solid understanding of the environment and bathymetry changes is essential for development of a reliable design alternative. Spur groins installed along the south slope of the North Jetty will assist in addressing scour generated by localized currents, but will not provide protection from overall MCR tidal shoal and channel morphological changes. Continued ebb shoal erosion and potential tidal channel movement could undermine the head of the proposed offshore spur groins (located near Stations 90 and 70). It seems likely that scour holes are related to the observed jetty tip recession. The 100 foot deep scour hole at the end of Jetty A is particularly alarming from a structural design perspective. Equally alarming is the discussion of "Vertical scour along the toe of the MCR jetties has exceeded 10 meters in some reaches" (Appendix A2, p. A2-11). If there really is, or was, a more than 30 foot high underwater scarp in places along the toe of the jetties, then more investigation is warranted. Figures showing typical sections often do not extend to the toe of slope, and show details that aren't feasible, such as rock limits ending in a small angle without an engineered toe. (See Appendix A1, Figure A1-258). Strategies to deal with scour, especially at the jetty tips appear undeveloped. Design features could include scour blankets, launched toes, or a program of regular fill using dredged material.
Significance – Medium:
Inadequate evaluation of the geomorphic processes responsible for the deterioration at the jetty tips (North Jetty and Jetty A) could lead to an incorrect approach to rehabilitation of those areas of damaged structures.

Recommendations for Resolution:
1. Conduct a more detailed evaluation of historical geomorphic changes in the outlet channel and shoals in order to evaluate tidal shoal erosion and tidal channel migration. Comparative analysis of historical bathymetric surveys would be helpful in developing a better understanding of historical trends and associated correlation with jetty structure historical damage, failure, and repair activities. Additionally, use historical geomorphic change analysis and hydrodynamic analysis to estimate long- term changes and impacts to the North Jetty and Jetty A to formulate jetty head rehabilitation alternatives and development of design criteria. 2. Do not limit the jetty repair preliminary designs to the footprint of the authorized jetties. Evaluate scour protection alternatives extending past the jetty tips. 3. Draft plans, profiles, and sections at this level of design using suitable software, such as AutoCAD® or MicroStation®. Microsoft Excel® is not an adequate substitute for drafting software. 4. Draft the jetty design typical sections to scale and extend past the scour holes and navigation channel. 5. Conduct a subsurface geotechnical investigation to obtain the geological properties needed to verify or design an adequate foundation.
USACE Final Evaluator Response (#18)
CONCUR There are many processes that drive scour effects along the toe of coastal structures. In the past, motivation of jetty scour at MCR has been due to many interacting processes. Initially, tidal channel re-alignment due to jetty construction was the dominate motivation for morphology change and scour. As the inlet responded to jetty incremental jetty construction during 1885 to 1939, channel re-alignment stabilized as the inlet equilibrated to its present configuration. Rip currents, tidal currents, vortex shedding and other secondary flow effects, and wave action are now the processes that are believed to affect scour along the jetties. Even if the hydrodynamic aspects of scour are fully understood, there remains the difficulty of coupling the hydrodynamics with sediment transport. Consequently, most scour prediction techniques consist of rules of thumb and fairly simplistic empirical guidance developed from laboratory and field observations. If consistent hydrodynamic conditions persist over a sufficient time span, scour holes and trenches eventually reach a stable configuration. What is known about jetty scour at MCR is based primarily on observation of bathymetry change over time and space, with insight being supplemented by hydrodynamic modeling. The scour depth realized at the terminus of the originally constructed jetties has stabilized to a point of equilibrium; scour depth is no longer increasing along the jetty tips. The scour at areas inshore of the jetty tips continue to evolve along each jetty, but a rate reduced from the initial stages of inlet response to jetty construction. Table A2-6 to A2-8 summarizes scour depths that have been observed to date along each jetty. This will be better explained in the report. The maximum vertical extent of scour is believed to have equilibrated, but the scour zone is believed to migrate along each jetty based on jetty head recession and landward recession of the shore-jetty root interface. Future projection of scour depth is presented in these tables, based on past scour trends. It is likely that the proposed spur groins will be subjected to some scour as the seabed locally adjusts to the presence of these elements. A given percentage of overbuild (10-

20%) has been included within the MCASES cost estimate to account for natural reshaping of the groins as they are placed.

For this study, the proposed implementation of Jetty Head features will occur on existing relic stone which is the remnant from previous jetty construction and repair sequences. Relic stone has been in its present configuration for more than 10 years at the areas proposed for jetty head features. Construction of jetty head features on relic stone serves two purposes, A) Keep the jetty head feature on the relic stone base and to avoid constructing the jetty features on scour-susceptible sand, and B) Minimize material cost and construction complexity by maximizing the use of a relic stone. If the jetty head template extends beyond (off) the relic stone, the quantity of material needed to complete the cross-section rapidly increases and the operating radius requirement (reach) for material placement rapidly increases. For all three jetties, the proposed jetty head feature would terminate significantly shoreward from the originally constructed jetty head. For the North and South jetties, the proposed "new" jetty head feature would be placed at a location 200 ft offshore from the present above water jetty terminus. For Jetty "A", the proposed jetty head feature would be placed at a maximum distance of 400 ft from the present jetty terminus. In all cases, the catch point for the jetty head feature is intended to be set back at least 10 ft from the fall line of the relic stone. The final location and configuration of the proposed jetty head features will be re-evaluated using detailed survey data and physical model studies (and refined) during the design documentation report phase prior to construction. Because the jetty head features will be constructed on a relic stone base, jetty head features are not expected to require scour blankets or launched toes.

The effect of toe scour on future life-cycle performance of jetty head features, has been evaluated using future scour depths presented in table A2-6 to A2-8. Future scour depth along proposed jetty head locations is estimated to extend below the present seabed elevation by 10-20 ft, depending on jetty location. The strategy for dealing with scour along the jetty head feature locations is to minimize the exposure of these features to scour by keeping the feature entirely on the relic stone AND to account for toe continued scour of the relic stone base in assessment of the jetty head feature.

Information relevant to assessing the scour processes include historical and present rate of scour at the jetty head, evolution of adjacent morphology, historical and present rate of recession of the jetty head, and expected stability of the relic stone base. Better explanation can be provided on the expected evolution of the adjacent morphology and the expected stability of the jetty head features proposed.

1. **ADOPT NOW**. Adopt by better summarizing the historical geomorphic changes in the vicinity of the jetties as well as the apparent stabilization of the most significant scour hole processes. The effect of toe scour on future life-cycle performance of jetty head features, has been evaluated using future scour depths presented in table A2-6 to A2-8.
2. **NOT ADOPT**. The jetty head repairs recommended in the Major Rehabilitation report are placed some distance back from the authorized jetty head location and are placed on large existing relic stone bases. The reasoning for building on top of the relic stone base is threefold: (1) set the jetty head back away from the more damaging

forces further toward the ocean (inlet), (2) build on top of a reworked and stabilized base, and (3) minimize construction costs by not extending the cross section into a deep and uncertain foundation.

3. **ADOPT in FUTURE**. The final design for the jetty head stabilization will be developed after physical model studies and a final detailed design report. At that time, more detailed design drawings will be developed.
4. **ADOPT in FUTURE.** Detailed design drawings will be part of the detailed design phase.
5. **NOT ADOPT.** Appendix B investigates the foundation issues related to the jetty repair alternatives. The vast majority of the jetty repair work builds on top of existing relic stone base which has been stabilized over years of existence at the MCR inlet

Panel Final BackCheck Response (#18)

Concur.

For Recommendation #3, development of conceptual design details were recommended as a typical planning level tool to ensure the proposed improvements are adequately represented for regulatory permitting and cost estimating. Errors in cross sectional configuration could result in substantial differences in volumes and costs. If they have been developed for the preferred alternative, they should be provided in the final report.

For Recommendation #5, additional information (multi-beam survey results, graphics, data, etc...) should be provided in the final report to show the extent and location of relic stone and graphically show the proposed footprint of improvements is within the zone of relic stone foundation.

Comment (#19):
Risk thresholds for selected alternatives are not clearly defined.
Basis for Comment:
Risk thresholds are used in repair frequency predictions as triggers for maintenance response and subsequently in maintenance cost predictions. The frequency of reaching degradation thresholds is predicted by risk thresholds. Combining degradation thresholds with repair costs (minor vs. major) can also be used to determine the threshold for triggering maintenance actions, balancing multiple small repairs against the cost of a single major repair. The Major Rehabilitation Evaluation Report includes extensive discussions of risks related to different portions of the project; however, while this discussion of risk is extensive, defined thresholds are not presented in the document. It is to be expected that the risk (probability) of surpassing thresholds may vary among alternatives in both configuration (number and placement of spurs, jetty length) and in cross sections considered. The risk associated with each alternative considered should be assessed based on materials, cross sections, supporting geological features, currents, and storms. It is also proper procedure to examine how the risk of one design component may be altered by the inclusion or exclusion of a second design component.
Significance – Medium:
Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected.
Recommendations for Resolution:
1. Define risk thresholds for alternatives, including source of risk and effect of exceeding the threshold.

USACE Final Evaluator Response (#19)
CONCUR Within the project event tree (and SRB model), there are three specific threshold parameters used to inform project performance or response actions. Two of the three threshold parameters pertain to jetty reliability. Reliability thresholds define when the structural and functional reliability for a given jetty transitions from a likelihood of satisfactory performance to a likelihood for unsatisfactory performance. Reliability thresholds are defined in table A2-3 and A2-4, and provide a time-varying indicator of overall jetty performance. Repair (maintenance) thresholds define when a given jetty segment will be repaired, based on the degradation of the jetty cross-section. The maintenance threshold serves to a trigger a life-cycle repair action, to minimize the chance of losing the function of a given jetty segment. Although there are no specific risk thresholds identified within the event tree simulation, the maintenance threshold is intended to manage (or reduce) the risk cross-section loss. The maintenance threshold serves to trigger a life-cycle response, and can vary depending upon the selected maintenance strategy. Table A2-12 list thresholds for activating maintenance response. These are conditional thresholds which are expressed in terms of the fraction of jetty cross-section area remaining within the upper part of the jetty cross-section that resists wave action. Using a cross-section area based threshold for triggering jetty maintenance actions emulates how the district monitors

the jetties and activates maintenance actions. The timing and frequency of jetty repairs, for a given maintenance threshold, is based on the rate of jetty cross-section degradation. Jetty degradation is a function of cross-section type (repair or rehab), materials & construction technique, exposure to wave action, and exposure to scour effects. 1. **ADOPT NOW**: PDT will supplement the report to describe how different maintenance thresholds address life-cycle performance.
Panel Final BackCheck Response (#19)
Concur.

Comment (#20):
It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
Basis for Comment:
Project life-cycle cost analyses should consider the risk of construction cycle and operational cycle downtime, which does not appear to be included. However, risks cannot be evaluated without understanding the level of uncertainty associated with the SRB model result. The uncertainty associated with actual future conditions, which may deviate from the modeled future conditions, is not apparent. The SRB model includes 600 variables (Section 9, p. A2-91) each of which has a data set which can be expected to reflect an associated variance. Depending on the calculation stream, these variances, applied geometrically, will lead to accumulated statistical errors and uncertainties. These cumulative internal variances can be expected to result in high uncertainty in the output of the SRB model, which should be considered in the evaluation of alternatives.
Significance – Medium:
Potentially wide error bars (uncertainty) may compromise life-cycle maintenance and repair schedules.
Recommendations for Resolution:
1. Quantify and explain the uncertainty (i.e., error bars) associated with each variable when analyzing processes that involve a chain of events. 2. Identify, analyze, and define errors that may accumulate to assess model reliability.
USACE Final Evaluator Response (#20)
CONCUR The cost data used within the SRB model to estimate future life-cycle costs associated with jetty construction are based on M-CASES estimates. The M-CASES estimates accounted for interruptions to the construction operations reflecting a non-optimistic production rate for jetty construction activities. The MII cost estimates identified specific cost and schedule risks elements for each alternative plan, to reflect a fully funded risk-based cost estimate for each plan. Refer to Appendix E for MII construction cost estimate details. The project event tree simulation (SRB model) included the MII uncertainties, when utilizing MII cost data within the model. Many of the 600 variables are constants, serve as conditional statement indicators, or are used for plotting and output synthesis. Approximately fifty variables serve as "variable" input used by the model. The PDT has performed a sensitivity analysis on 11 primary variables that affect life-cycle performance. 1. **ADOPT NOW**: Isolate the variable input parameters, provide updated and additional discussion of sensitivity analysis for 11 primary input variables. 2. **ADOPT NOW**: Provide additional information showing output metrics with uncertainties.
Panel Final BackCheck Response (#20)

Concur.
Comment (#21):
The model output parameters and wave height components are not clearly explained and supported.
Basis for Comment:
The meaning of the following SRB model output parameters is not clear: • Functional Reliability • Structural Reliability • Probability of Unsatisfactory Structure Performance. For example, the main report (Section 3.6.1, p. 3-43) includes the following: "Functional reliability is the likelihood that a structure will satisfactorily perform its intended function within a given time interval. Functional reliability is derived by combining structural reliability metrics with metrics that describe the present structure cross-section configuration." One difficulty is that the understanding of "Functional Reliability" requires first understanding "structural reliability metrics", (which are not to be confused with "metrics that describe the present cross-section configuration"). However, the "structural reliability metrics" are not clearly defined either. A word search of Appendix A2 for the term "Structural Reliability" does not reveal a set of equations for calculating the parameter or a clear explanation. Similarly, much of the SRB model includes terminology and variables that are hard to understand. For example, Table A2-12, Jetty Maintenance Thresholds, (p. A-60) consists of numbers and parameters not connected to anything that has a physical meaning. Conventional calculations and metrics such as volumes, areas, and depths are parameters with physical meaning that would improve the understanding of the SRB model. Understanding the SRB model outputs would be improved with graphics that are connected to parameters with physical meaning. The wave height component of the SRB model is not supported by standard coastal engineering practice. Progressive jetty damage in the SRB model is based on a stochastic time series of wave heights, which is derived from "An ensemble of 52 storm events … recorded at NDBC buoys… during 1998 to 2008." It is unclear why only 10 years of buoy data were used when a longer record of more than 17 years with gaps removed is available (Appendix A1, pp. 34 and 37). It is also not certain that extreme wave height events were properly included in the SRB model process. It is common industry practice to test a coastal engineering design using a specific design environmental criterion, such as the 100 year return period wave height.
Significance – Medium:
The model parameters that compare alternatives lack a physical meaning, such as a volume of rock or depth of scour. It is therefore difficult to verify, calculate, or evaluate whether the parameters used or model results are reasonable.

Recommendations for Resolution:
1. Explain and demonstrate how the model output parameters relate to physical performance measures, with graphics or figures. 2. Measure jetty damage and performance with conventional calculations, and commonly applied metrics, for example: a. Volume of sediment entering the navigation channel, or dredge volume, b. Depth or volume of scour at the jetty toe c. Volume or area of armor rock displaced from the jetty. 3. Test the design against a specific storm event, such as the 100 year return period event. 4. Calculate the return period of extreme events using the complete record of measured offshore wave data.

USACE Final Evaluator Response (#21)
CONCUR Structure reliability is estimated using the dynamic performance functions as described in A2-Section 3. Those stability performance functions include frontside slope stability and backside slope stability (from overtopping). The various equations that went into this calculation can be found on pages A2-25 to A2-36, and include the Hudson Equation, Van der Meer Equations, Walker-Palmer-Duhnam, and Van Gent equations. The functional reliability as it is utilized in the project event tree simulation combines the projected structural reliability of the cross section with the volume left in the above water portion of the cross section (i.e. the robustness of what is left) to translate that to a parameter that estimates the likelihood of that part of the structure losing its ability to function. This approach follows Corps Major Rehabilitation guidance on calculating probability of failure and risk. The thresholds in Table A2-12 are conditional thresholds which are expressed in terms of the fraction of cross-section area remaining within the upper part of the jetty cross-section. The upper region is the area of the jetty that resists wave action (Page A2-23 and A2-53 to A2-56). The threshold values in Table A2-12 are the decimal fraction of the "standard template"; i.e. 0.15 is 15% of the upper cross section. The "standard template" for each jetty is defined on page A2-62 and in Table A2-13. When the jetty cross-section is damaged to a level that exceeds (is lower than) the prescribed threshold values, the jetty cross-section is repaired. Using a (remaining) cross-section area based threshold for triggering jetty maintenance actions emulates how the district monitors the jetties and activates maintenance actions. A supplemental discussion of jetty damage thresholds (Table A2-12) and the standard cross-section template (Table A2-13) will be provided. It is important to note that the SRB model is a project event tree life cycle simulation model. The basic and progressive steps of jetty cross section damage, accumulated damage with successive events, identification of a maintenance action or failure event are all stepped through on an annual basis for the three jetties as required by Major Rehabilitation guidance. Existing SRB output graphics show the simulated reduction in jetty cross-section area over time (for hindcast conditions due to wave and scour damage processes) for a selected cross-section (figure A2-18a-c, A2-25b, A2-26b, A2-27b). Figure A2-18a shows simulated cumulative toe-scour depth for a given North Jetty cross-section hindcast (Sta 84+50). The observed values for toe scour realized at this location are shown in Table A2-6. The description of SRB scour estimates will be expanded to compare simulated scour values to observed values. We will supplement the report with graphics and added discussion that

show simulated tonnage of jetty damage sustained by the cross-section corresponding to the cross-section area reduction for a given cross-section. Jetty damage (area) simulated by the SRB model will be compared to other calculations (Hudson). Graphics and discussion will be added to compare repair tonnage simulated by the SRB model vs. observed values for the hindcast. Graphics and discussion will be added to compare SRB forecast values of jetty repair tonnage vs. other estimating techniques. Supplemental information will be provided to describe the incremental volume of sediment predicted to enter the navigation channel due to jetty head recession and shore edge recession.

The report will be modified to better explain the above extremal wave height information. The offshore wave height history utilized encompasses the entire period of record for the Columbia River NDBC buoy (1987-2008) and the estimates of annualized return interval (Figure A1-70 and A1-71) match closely with those developed by Ruggiero recently for the Oregon coast. The transference of observed offshore wave conditions to the MCR jetties is problematic without using the observed wave spectra (directional) as an offshore boundary condition (BC). The offshore wave environment in the PAC-NW is too complex to describe by parameterized spectra. Directional offshore wave data (spectra) for the MCR is available from 1998 onward. This is why the ensemble of 52 offshore wave events (BCs) is pooled from 1998-2008. The BC ensemble included the three largest observed wave events on record for the MCR offshore region (1987-2008), which are shown in figure A1-68. Appendix A1 describes how the 52 storm wave conditions were used to emulate the sub- to inter-annual nearshore storm wave climate, as imposed by the offshore storm wave climate shown in figure A1-70-71 (see page A1-39 to A1-43). The project event tree life cycle analysis simulates on an annual basis both the range of potential incident deep water wave heights as well as the number of storms occurring per year. Additional graphics and discussion will be provided to demonstrate that the above process is reproduced by the SRB model. An estimate (graphic) of the return period from nearshore storm wave conditions will be provided, based on the featured ensemble of offshore wave conditions. The high-end of return period for nearshore waves (from above graphic) will be used to assess the design alternatives for survivability.

1. **ADOPT NOW**. Adopt now. All of the output model parameters are intended to contribute to an annual cross section condition, volumes and frequency of repair stone needed, volume and frequency of dredged material volume expected. A supplemental discussion of jetty damage thresholds (Table A2-12) and the standard cross-section template (Table A2-13) will be provided. The physical performance measures simulated by the model will be better explained and verified. When applied to a coastal structure such as a rubblemound structure, the design equation indicates when the armor stone is expected to be mobilized. Subsequent to that we calculate how much stone we expect to be taken off of the structure and whether or not the whole cross section is compromised. Normally, and within the model, the damage accumulates from year to year until a more severe damage state occurs. This whole damage evolution process is not captured in any conventional design equation, however, I believe the SRB model captures that process very well and also reproduces 100 years of hindcast evolution of the structure.

2. **ADOPT NOW** Adopt now by better explaining the physical processes simulated in the model and comparing to other reasonable calculations of the processes. The description

of SRB scour estimates will be expanded to compare simulated scour values to observed values. We will supplement the report with graphics and added discussion that show simulated tonnage of jetty damage sustained by the cross-section corresponding to the cross-section area reduction for a given cross-section. Jetty damage (area) simulated by the SRB model will be compared to other calculations (Hudson). Graphics and discussion will be added to compare repair tonnage simulated by the SRB model vs. observed values for the hindcast. Graphics and discussion will be added to compare SRB forecast values of jetty repair tonnage vs. other estimating techniques. Supplemental information will be provided to describe the incremental volume of sediment predicted to enter the navigation channel due to jetty head recession and shore edge recession. The calculations utilized in the model are conventional and according to USACE Major Rehabilitation reliability analysis methods. Explanation will be provided which ties jetty and shoreface recession estimates with the channel infill volume volumes noted in table A2-5. Standard damage and performance modes were applied to all three primary structures. Attachment 1 illustrates the primary damage modes. Physical modeling results helped in quantifying the actual progression of damage for a given cross section. Tables A2-5 through A2-14 provide some of the information referred to in this recommendation. (See attachment 2.) Attachment 3 summarizes various locations in the report that address the physical processes incorporated in the analysis.

3. **ADOPT NOW** Adopt now by demonstrating how the current analysis exposes the jetty structures to typical extreme events and quantifies the respective damages to the events.
4. **ADOPT NOW** Adopt now by better explaining the analysis already performed for the study which includes the complete record of measured offshore wave data. The cumulative distribution curves provided for incident wave height along the jetty lengths will be compared to the extremal analysis results to demonstrate the appropriate exposure to extreme conditions within the annual loading processes in the model.

Panel Final BackCheck Response (#21)

Concur.

The additional analysis described in the Evaluator Response partially addresses the issue; however, the fundamental problems with the SRB model remain.

Some of the “adopt now” statements include a description of future work that is not consistent with the recommendation. Recommendation No. 3 is to “Test the design against a specific storm event such as the 100 year return period event”. The corresponding adopt now statement discusses how to clarify that the existing analysis includes “typical extreme events”. They are not the same thing.

Comment (#22):

The culvert installation details, as well as potential impacts, need further clarification.

Basis for Comment:

The Major Rehabilitation Evaluation Report states that the existing culvert has increased scour and adversely affected the North Jetty, and that it will be relocated. There are a few sentences in the main report and in Appendix D that mention the culvert, but there is not enough information provided in the main report to determine if there will be any potential impacts from the new discharge location. The table at the end of Appendix D provides the most detail anywhere in this report regarding the culvert relocation. On p. 6-6 in the main report there is a sentence stating work will begin in 2014 to install a culvert to divert overland flow to another area that will not impact the North Jetty root stability. While this sounds like a reasonable approach to protect the North Jetty, more information is needed to clarify the impact such as the source of the water, an assessment of the water quality, and an estimate of the flow rate involved. Without knowing the exact new location, it is not possible to assess the potential environmental impact of relocating this water flow.

Significance – Medium:

More detailed information on the new location of the culvert as well as water quality, flow rates, and source of the water is necessary to determine the environmental impact of the relocation.

Recommendations for Resolution:

1. Add one paragraph in the main report that addresses the culvert relocation.
2. Present any available data on the water quality, flow rates, and water source of water discharged through the culvert.
3. Provide the specific location planned for new culvert.

USACE Final Evaluator Response (#22)

CONCUR

The purpose of the culvert, the size and the method of replacement will be expanded on in the main report. The existing culvert is failing and replacement is not anticipated to vary extensively from the original installation. The lagoon fill project is intended to stabilize The North side of the North Jetty by preventing scour that is caused by water flowing parallel to the jetty.

1. **ADOPT NOW.** A paragraph will be added to the main report discussing the culvert relocation.
2. **ADOPT in FUTURE**. Available data on the water quality, flow rates and water source as well as detailed design information will be presented in the Design Document Report for this portion of the project.
3. **ADOPT NOW.** The specific location of the culvert will be shown in the report.

Panel Final BackCheck Response (#22)

Concur.

Comment (#23):
The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
Basis for Comment:
The terms "project life" and "period of analysis" are not defined or differentiated, and the project base year varies throughout the report: • In the economic spreadsheet models, the NPVs are calculated for differing periods of analysis (2009-2070 for South Jetty, 2008-2070 for Jetty A, and 2008-2070, 2008-2057 and 2008-2069 for the North Jetty); whereas the AACs are based on a 50 year period of analysis. • The period of analysis extends 50 years beyond the base year of 2011 when discussing sea level rise (pp. A1-38 and A2-68). • The period of analysis for future condition simulations is 64 years (2006 to 2970) for the North Jetty and Jetty A and 63 years (2007 to 2070) for the South Jetty (p. A2-78). • The AAC is calculated using an amortization factor applied to the present year cost stream from the NPV implementation year (2006/2007) to 2069 (p. A2-51). • The base year of the economic analysis is not identified in Section 2 or Appendix C, but is stated as 2014 elsewhere in the report (pp. ES-3 and A2-78). • Within the SRB model, the base year is stated as 2011 when discussing sea level rise (pp. A1-38 and A2-68). • Within the SRB model, the base year for NPV cost discounting is 2006 for the North Jetty and Jetty A, and 2007 for the South Jetty (p. A2-51).
Significance – Low:
Inconsistencies in terminology and periods of analysis can lead to misunderstanding of findings and results.
Recommendations for Resolution:
1. Define and differentiate between the terms "project life" and "period of analysis." 2. Revise the report to eliminate inconsistencies between the varying periods of analysis. 3. Use a consistent base year throughout the analysis, and revise the report to reflect consistency. 4. Revise Section 2 and Appendix C of the report to state the year that is considered to be the base year, the length of the period of analysis, and the calendar years that are included in the period of analysis. 5. Provide definitions of all terms in a Glossary.

USACE Final Evaluator Response (#23)
CONCUR **1. ADOPT NOW.** Each term will be clarified and used consistently. **2. ADOPT NOW.** The report will be revised to reflect that all NPVs and AACs are calculated using the same base year and period of analysis. Spreadsheets used for these calculations will be revised and archived with the appropriate calculations shown. **3. ADOPT NOW.** The base year for each jetty will be the same, and the Year labels in the

spreadsheets will be modified to reflect that each stream of costs begins and ends at the same time. **4. ADOPT NOW.** Section 2 and Appendix C of the report will be revised to state the year that is considered to be the base year, the length of the period of analysis, and the calendar years that are included in the period of analysis. **5. ADOPT NOW.** A glossary of terms will be included in the report.
Panel Final BackCheck Response (#23)
Concur.

Comment (#24):

Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.

Basis for Comment:

Data presented throughout the report have inconsistencies that should be corrected. The following are examples of inconsistencies in values for cargo tonnages, vessel trips, and value of cargo:

- Page ES-1 – cargo on the MCR is 45 million (M) tons and 3,500 vessel crossings based on 2008 Waterborne Commerce Statistics Center data. These data are not cited in the body of the report.
- Page 1-2 – cargo on the MCR is 40 M tons worth $17 billion, with 12,000 commercial vessels navigating the MCR annually.
- Pages 2-1 and C-1 – cargo on the MCR is 40 M tons valued at $17 billion based on a 2009 Pacific Northwest Waterways Association (PNWA) factsheet cited in Appendix C.
- Pages 1-4 and C-4 – cargo on the MCR is 32 M tons in 2003 and projected at 43 M tons in 2020 based on 2005 Center for Economic Development and Research (CEDER) data, cited as a footnote in Appendix C.
- Page C-5, Table C-1 – 5,364 total vessel trips on the MCR based on 2005 Waterborne Commerce Statistics Center data.
- Page A1-3 – cargo on the MCR is 48 M tons worth $16 billion, with 12,000 commercial vessels navigating the MCR annually.

The cargo and vessel trip statistics presented in the report appear to include all traffic on the MCR and Lower Columbia River (LCR). The report assumes all traffic accessing the MCR is dependent on the MCR jetties. The without-project condition channel depths are not adequately described. The cargo and vessel trips that would be impacted by the jetties, that is, the portion of the fleet transiting the MCR that would be restricted by the without-project condition channel depths, is not described.

Significance – Low:

Consistent cargo and vessel trip data for the MCR are needed in order to develop an understanding of the significance of the jetties.

Recommendations for Resolution:

1. Describe the cargo tonnages, vessel trips, and value of cargo consistently throughout the report, or supply an explanation of the differences and why various data sources were used.
2. Describe the portion of the fleet accessing the MCR that is dependent on the jetties (i.e., what are the without-project condition channel depths and what portion of the fleet transiting the MCR would be restricted by the without-project condition channel depths).

USACE Final Evaluator Response (#24)

CONCUR

The various sources and presentations of the cargo volume will be reviewed for consistency.

1. **ADOPT NOW** A table containing the different sources for cargo data will be included in the Main Rehab. Report.

2. NOT ADOPT The MCR Jetties have an extensive affect on the morphology of the MCR, not just the channel depth. It is not practicable to attempt to estimate the overall condition of the River Mouth if the Jetties were not there.
Panel Final BackCheck Response (#24)
Concur. In addition to including a table showing the different sources of cargo data, include an explanation of why different data sources were used.

Comment (#25):
Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.
Basis for Comment:
Inconsistencies in terminology can make understanding the project difficult. Commonly used terms in the document, such as “failure,” are not clearly and qualitatively defined. Phrases such as “close to failure” appear frequently, in a qualitative sense, but without an understanding of how much jetty damage, if any, constitutes a “failure.” Another example is in the SRB model where “fix-as-fails” repairs are described as, “To defer jetty maintenance for as long as possible, the jetty is maintained close to the margin of functional loss.” The concept makes sense but how the model deals with terms like “as long as possible” and “close to the margin of functional loss” is unclear. Other phrases, such as “scheduled repair” and “rehabilitation” seem to be inconsistent as well. For example, “scheduled repair” includes “head capping” in the executive summary of the main report, but does not include “head capping” in some alternatives analyzed by the SRB model.
Significance – Low:
Without clear, consistent definitions of terminology, it is difficult to understand exactly what is being proposed or analyzed and can lead to misinterpretations.
Recommendations for Resolution:
1. Add a Definitions list or Glossary to the document.
USACE Final Evaluator Response (#25)
CONCUR The discrepancy in the naming conventions for the jetty repair and rehabilitation plans will be reviewed and clarified. **1. ADOPT NOW**. A glossary will be added to clarify terminology.
Panel Final BackCheck Response (#25)
Concur.

REPLY TO
ATTENTION OF

CECW-P

15 August 2011

MEMORANDUM FOR Director, Deep Draft Navigation Planning Center of Expertise (DDPCX)

SUBJECT: Request for Approval of the Stochastic Reliability-Based Model for the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River.

1. The Columbia River model is a stochastic reliability-based (SRB) model designed to determine the most cost-effective and reliable method of maintaining and repairing the jetties at the mouth of the Columbia River. The model has been reviewed to determine if it satisfies the certification criteria in EC 1105-2-412. Because the model is used to evaluate the potential effects of alternatives, EC 1105-2-412 is applicable. The HQUSACE Model Certification Panel has determined that the certification criteria have not been met and the model is therefore not certified or approved for use at this time.

2. As stated in the Memorandum from the DDPCX, this was a Level 1 review, meaning that a highly complex model was used in the decision making and that there could be a high risk of making an incorrect investment decision. Several shortcomings were identified by an independent external peer review panel. The HQUSACE Model Certification Panel generally agrees with the findings and recommendations of the external panel and suggests that the district use the ATR and IEPR comments to develop a path forward.

3. The IEPR panel commented that the SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis. It further commented that the SRB model functions as a "black box" and does not allow an analysis of alternatives that is clearly based on sound technical evidence of engineering design performance. The model lacks clarity and support for the interaction between economic consequences and engineering function. The panel commented that while many elements of the SRB model are appropriate and required per USACE guidance and standard engineering practice. The SRB model does not have to fully incorporate all engineering reliability modeling components. However, the reliability modeling output must be consolidated with economics within the model, particularly in terms of hazard or fragility curves and how they respond to repairs. The ATR reviewer strongly recommended that the SRB process and results be validated with a simpler model using hazard functions from the SRB reliability curves and the development of consequences using a traditional economic simulation model. The IEPR Panel further commented that the model seems inappropriate based on USACE published guidance, does not support the project goals, has not been verified and validated, and should not be relied upon.

4. The HQUSACE Model Certification Panel understands that ATR suggestions were not implemented and the IEPR comments were submitted after the DDPCX's request for model approval. The model and IEPR concerns are significant, and it is not expected that the concerns could adequately be addressed without considerable additional effort. If the district chooses to

address the ATR and IEPR comments, the DDPCX must submit additional supporting information for panel consideration. Otherwise, the district has indicated that the results of the model will not be used in the Major Rehabilitation Report if the model is not approved for use. In the absence of an approved model, the district, MSC, and DDPCX should collaborate on the analyses required for a technically (engineering, economics, environmental) sound and policy compliant decision document.

HARRY E. KITCH, P.E.

REPLY TO
ATTENTION OF

CENWP-PM-F

MEMORANDUM FOR Chief, NWD-PDD

SUBJECT: Request for vertical team concurrence on path forward for approval of the MCR Major Rehabilitation Report

1. Request your concurrence and endorsement of this memo defining the Portland District's path forward.

2. Based on a draft memo regarding disapproval of the SRB model from CECW-P, the district has developed a proposed path forward to ensure approval of a Major Rehab Report (MRR) in time for the FY 14 budget submittal. The district is requesting NWD, DDPCX and HQUSACE concurrence—from both a technical and policy standpoint.

3. The Portland District will partner with an A-E contractor to revise the planning model and complete the MCR Major Rehabilitation Report. Upon completion of the revised model, the district will submit a request and supporting documentation for model approval for use to the DDPCX and HQUSACE.

4. A district intends to perform a new ATR on the revised final MRR. In addition, the PDT will thoroughly document how the three outstanding IEPR comments (2, 4 and 8) have been resolved and request concurrence through the vertical team. Sediment analysis concerns noted in comment 2 will be addressed by citing a comprehensive, multi-agency study that is ongoing. Comments 4 and 8 will be directly addressed through the actions described above to fully document the engineering analysis.

5. The PDT will also change and update appropriate parts of the following MRR information: (a) the base condition will incorporate Major Maintenance Report (MMR) changes for critical NJ repairs and lagoon mitigation; (b) stone quantities and MCACES cost estimate and fully-funded cost; (c) the economic analysis; (d) plan formulation; and (e) upon vertical approval of the path forward, the review plan and project management plan.

6. The following MRR information from the 90-percent draft document will not be altered unless the engineering analysis results in substantive changes to the selected plan: (a) draft FONSI signed on 31 May 2011; the Mitigation Plan, 404(b)(1), Final EA and BA/BiOp; (b) Geotechnical Studies; and (c) Cost-Schedule Risk Analysis.

7. To execute the actions discussed in paragraphs 2 through 5, the District will develop a detailed Plan of Study including project schedule and milestone check-ins with the vertical team. Pending vertical team approval of the district's path forward, the PDT plans to have a 90-percent draft MRR completed by 30 November 2011 and a final MRR by 28 March 2012.

8. Point of contact for this is Eric Bluhm, at 503-808-4759.

Kevin J. Brice, P.E. PMP

Model Approval Plan
(Supplemental)

Stochastic Reliability Based
MATLAB model
MCR jetties

Mouth of the Columbia River
Major Rehabilitation Report

CENWP

1. Purpose

The purpose of this Model Approval Plan is to outline the review process and requirements necessary to assure the quality of the Stochastic Reliability Based MATLAB model for the MCR jetties (SRB), as submitted from the CENWP to the DDPCX in support of the Approval for Single Use of the model in the Mouth of the Columbia River, Major Rehabilitation Report (MCR MRR). This review plan is based on the requirements contained in *EC 1105-2-412 Assuring Quality of Planning Models* and the *Standard Operating Procedures for the Processing of Planning Model Certification/Approval Actions,* which complements Engineering Circular 1105-2-412 (EC) and provides a guideline for implementation of the EC. The MCR SRB model has been in development since 2005, significantly pre-dating the EC, therefore the model is in the latter stages of the review/approval process. This plan is intended to capture what has already been done and describe how the PDT intends to complete the model approval process.

2. Reference and Guidance

2.1. Engineering Circular 1105-2-412, Assuring Quality of Planning Models, 31 March 2011.
2.2. Budget Engineer Circular (EC) 11-2-199, dated 31 March 10
2.3. Standard Operating Procedures for the Processing of Planning Model Certification/Approval Actions dated 16 November 2010

3. Background

Stochastic Reliability Based (SRB) model developed for the Mouth of the Columbia River (MCR) evaluates the expected reliability of different alternative cross-sections of the three existing jetties. The wave climate and damage function currently used in the model are specific to the MCR. EC 1105-2-412, Assuring Quality of Planning Models makes a distinction between model certification and model approval based upon the origin of the model and the extent of the model's intended use; Section 5. c stipulates that models that have been developed by the corps (or outside entities) and are viewed by the vertical team as single-use or study specific models require model approval. Models which will be used over a wider range of conditions and locations require certification. At this time the PDT recommends that the MCR SRB model be considered a Regional/Local Model as defined EC 1105-2-412 section 5. a. (2) and that it be reviewed for approval, not certification due to it being specific to the MCR jetties in its current form.

The MCR SRB model has been developed over several years and has been subjected to an Agency Technical Review (ATR). After incorporating comments the model was reviewed during the Independent Engineering Peer Review (IEPR) of the MCR Major Rehab Study (Attachment 1). The MCR SRB model has not received approval for use from HQUSACE and two IEPR comments that were specific to the model have not been resolved. In order to address the IEPR team's unresolved comments CENWP solicited the assistance of the firm Moffat and Nichol via a two phase task order to review the model, associated documentation and engineering regulations and identify specific changes that need to be made in the model code and assist CENWP in making those changes. Phase I of the task order produced a letter report (Attachment 2) that evaluates the functionality of the MCR SRB model and identified nine specific improvements to the model code that address the outstanding concerns regarding the model. All nine of the recommendations were adopted by the PDT and two additional tasks related to including the updated model and the results into the MCR Major Rehabilitation Report (MRR) were incorporated into the task order modification for phase II (Attachment 3).

3.1 Previous Reviews

A review plan for the MCR Major Rehabilitation Report was last revised in September 2010 and submitted to the DDPCX for consideration. The review plan described the series of reviews for the different elements required for the report.
This Review Plan (RP) outlined the reviews as required by EC 1105-2-410. The RP supplements the Project Management Plan (PMP) and identified three levels of peer review: District Quality Control (DQC), Agency Technical Review (ATR), and Independent External Peer Review (IEPR) based on the scale, impacts, and cost of this project.
All decision documents and their supporting analyses have undergone DQC, ATR and IEPR, to "ensure the quality and credibility of the government's scientific information", in accordance with EC 1105-2-410 and the quality management procedures of the responsible command. The Circular addresses review of the decision document as it pertains to both approaches and planning coordination with the appropriate Center. The Circular also requires that DrChecks be used to document all ATR and IEPR comments, responses, and associated resolutions accomplished. These requirements have been met for the multiple components of the MCR MRR and the comments and responses are attached to this model review plan for consideration.

The types of technical reviews that were conducted are provided below.

3.1 a District Quality Control (DQC).

DQC is the review of basic science and engineering work products focused on fulfilling the project quality requirements defined in the Program Management Plan (PMP). It was managed in the home district and may be conducted by staff in the home district as long as they are not doing the work involved in the study, including contracted work that is being reviewed. Basic quality control tools include a Quality Management Plan providing for seamless review, quality checks and reviews, supervisory reviews, Project Delivery Team (PDT) reviews, etc. Additionally, the PDT is responsible for a complete reading of the report to assure the overall integrity of the report, technical appendices and the recommendations before approval by the District Commander. It is expected that the MSC/District quality management plans address the conduct and documentation of this fundamental level of review. DQC is not covered by this Review Plan. The MCR MRR was assigned a separate DQC review team to present an unbiased opinion of the technical merits of the report. The DQC team was led by the Deputy Chief of Engineering and Construction and the review resulted in XXXX comments and responses which had a dramatic improvement on the report.

3.1 b Agency Technical Review (ATR).

ATR (which replaces the level of review formerly known as Independent Technical Review) was an in-depth review, managed within USACE, and conducted by a qualified team outside of the home district that was not involved in the day-to-day production of a project/product. The purpose of this review was to ensure the proper application of clearly established criteria, regulations, laws, codes, principles and professional practices. The ATR team reviewed the various work products and assures that all the parts fit together in a coherent whole. The ATR team was comprised of senior USACE personnel, the ATR team roster is attached. To assure independence, the leader of the ATR team was chosen from outside the home MSC.

3.1 c Independent External Peer Review (IEPR).

This is the most independent level of review, and is applied in cases that meet certain criteria where the risk and magnitude of the proposed project are such that a critical examination by a qualified team outside of USACE is warranted. The criteria for application of IEPR include, but are not limited to (1) the total project cost exceeds $45 million; (2) there is a significant threat to human life; (3) it is requested by a State Governor of an affected state; (4) it is requested by the head of a Federal or state agency charged with reviewing the project if he/she determines the project is likely to have a significant adverse impact on resources under the jurisdiction of his/her agency after implementation of proposed mitigation (the Chief has the discretion to add IEPR under this circumstance); (5) there is significant public dispute regarding the size, nature, effects of the project; (6) there is significant public dispute regarding the economic or environmental cost or benefit of the project; (7) cases where information is based on novel methods, presents complex challenges for interpretation, contains precedent-setting methods or models, or presents conclusions that are likely to change prevailing practices; or (8) any other circumstance where the Chief of Engineers determines IEPR is warranted. IEPR may be appropriate for feasibility studies; reevaluation studies; reports or project studies requiring a Chiefs Report, authorization by Congress, or an EIS; and large programmatic efforts and their component projects. It was determined that MCR MRR warranted an IEPR. The IEPR was managed by Bechtel, an eligible outside organization. The scope of review addressed all the underlying planning, engineering, including safety assurance, economics, and environmental analyses performed, not just one aspect of the project. A review of the attached charge questions given to the IEPR team indicates that the MATLAB model received a comprehensive review by qualified programmers and ocean engineers. The IEPR charge questions and comments and responses are attached. Three of the IEPR comments resulted in comments and responses dialogues where the IEPR team and the PDT were unable to reach concurrence.

3.2 Post IEPR Activity

In an effort to resolve the non-concur items identified in the IEPR, CENWP engaged the services of Moffatt & Nichol and together with the PDT has outlined a path forward to resolve the open IEPR comments by improving the model code, allowing for the transparency, compliance with current technology and corps policy, documentation, practicality with data inputs and outputs and clearly identifying the use and limitations of the model consistent with EC 1105-2-412. Following is a list of the steps contained in EC 1105-2-412 and the actions that the PDT has either taken or propose to take to satisfy those steps:

Step 1: Proponent Identifies model to be used for a national, regional or local application and PCX determines the need for certification or approval.

Response: The proponent is CENWP, and we have identified the model as Regional/Local model developed by USACE with assistance from a non-corps entity (Moffat & Nichol) as a study specific model, therefore the PDT believes model approval not certification is required.

Step 2: Proponent submits model and documentation to the appropriate PCX.

Response: PDT has forwarded the model code, ATR and IEPR comments to the DDPCX. DDPCX determined that the model was not approvable via memo indicating that the PDT should resolve outstanding IEPR comments prior to approval. PDT has engaged an expert modeling team from a qualified AE firm. Updated model and documentation will be sent to DDPCX for review and approval.

Step 3: PCX determines appropriate level of review utilizing the criteria outlined in EC. PCX has final approval on level of review.

Response: The MCR SRB model development predates the EC, so a formal review level was never assigned. It is assumed by the PDT that the model will require a level 1 or level 2 review.

Step 4: PCX establishes a review team, team leader and defines the anticipated charge scope of review. The review charge and scope should guide the product reviewers and direct them to key issues, assumptions, routines and aspects for review. A team selected from the roster of qualified reviewers maintained by the appropriate PCX, including external and internal reviewers, will conduct Level 1 and Level 2 reviews. Level 3 and Level 4 reviews may be conducted by Corps internal experts, but the review team, as deemed appropriate by the PCX, could include external individuals as well. Protocol and procedures for the model review process will be specified in the PCX standard operating procedures (SOP) and will reflect prevailing industry practices.

Response: The MCR PDT worked with the PCX (if it wasn't DDPCX then list who please) to conduct the model ATR and the overall MCR Major Rehabilitation Report (MCR MRR) IEPR, which included an extensive number of PCX recommended questions regarding the model, modeling process and interpretation of the results into the MCR MRR. The results of both reviews have been received by the DDPCX. Outstanding comments from the IEPR are being resolved as previously described and it is the belief of the PDT that the resolution of the comments shall conclude the review process and provide the DDPCX with the information and documentation required to render approval.

Step 5: The PCX develops a certification plan to include to include the information from steps 1-4, defining the scope of the review. The certification plan (and accompanying model documentation materials) is submitted to CECW-P for approval. Written approval from CECW-P must be received by the PCX prior to proceeding with the certification review.

Response: The MCR PDT has been pursuing an overall Major Rehabilitation Report approval process, of which the model approval is a component. The MCR PDT engaged the vertical team as well as the relevant PCX(s) to develop a review and approval plan early in the development stages of the project. The review plan included DQC, ATR (model specific and report) prior to conducting an IEPR. The PDT would like the DDPCX to give consideration to the previously conducted reviews, the changes generated from the reviews and the future actions described in this plan. If there are additional steps required that has not been completed or proposed in this plan please identify and the PDT will include them prior to submission for approval.

Step 6: Once the PCX has received approval to proceed, the PCX will hold an initial meeting to begin the certification process to assure that all participants understand the nature of the effort, as well as to discuss any particular technical or administrative issues that will be important in the review. The meeting (which can be held by teleconference) will include representatives of the PCX, the model proponent and the review team. CECW-P will be notified of the meeting and invited to attend.

Response: The goal of the project's proponent, CENWP, is to complete the revised MCR MRR in time for submission in the FY 14 budget request. In order to accomplish this goal the PDT requests that the PCX forward the review plan to CECW-P as soon as possible and schedule the teleconference to assure that the actions proposed by the PDT are consistent with the requirements for model approval.

Step 7: In fulfilling it's role, the review team will provide to the PCX a consolidated documentation of review comments and recommendations. The review should adhere to the review charge and scope provided by the PCX. The PCX will strive for consensus, but one or more reviewers may not concur with the views of the majority. Matters of disagreement should be addressed forthrightly in the report. As a final recourse, a reviewer may choose to prepare a brief dissent describing the issues of contention and arguments in support of the minority view. To encourage reviewers to express their views freely, the review comments are treated as panel responses and are given to proponents with identifiers removed.

Response: This process was conducted during the rigorous IEPR conducted from November 2010 through March 2011. The review team was comprised of external experts and the review was conducted according to the process described in EC 1165-2-209 and supplemental implementation guidance. The charge questions were developed with the assistance of the PCX and are attached to this plan as appendix D. A review of the charge questions will demonstrate that the IEPR team was directed to review the model carefully and render a professional opinion on the quality and to make recommendations on how to overcome deficiencies noted. The PDT is currently pursuing their recommendations.

Step 8: Review comments are provided to the PCX within 90 days after submittal of the model for review to the review team. (Ninety days is the estimated maximum time for review of models in level 1. For models in other categories, the review time will be adjusted accordingly, and is expected to be less than 90 days.) The PCX then assesses whether the review team fulfilled the charge and scope provided. When the PCX determines that the review charge and scope have been met, the comments are provided to the proponent for review and response, and a checkpoint meeting is scheduled to discuss the review comments and issues for response. The checkpoint meeting will be held with the same parties as the initial meeting in Step 6, above.

Response: The IEPR process is in the final stage, resolution of outstanding comments. The charge questions provided and agreed upon by PCX and PDT were the basis of the IEPR.

Step 9: Feedback from the proponent, within 30 days after receipt of the comments, is transferred through the PCX back to the review team until all comments are either resolved or all parties reach an agreement on outstanding issues. The PCX will strive to resolve all comments, but not all comments may be resolved. CECW-P in consultation with the HQ Model Certification Panel, the proponent and the PCX will have the final decision on comment resolution and product certification/approval. The final decision on model certification/approval should be made within 90 days after initial submittal of review comments to the proponent. (In cases where substantial revisions are made to the model, this time period may be longer).

Response: The project is currently at this stage. The outstanding comments are being resolved by streamlining the model, increasing transparency and reconfiguring the model code into modules in order to track interim results. The SRB model will be reconfigured in order to provide the ability to utilize an input files that generate discrete output results. This process will increase the ability of the PDT to evaluate alternatives quickly and efficiently.

Step 10: The PCX will furnish Headquarters Planning Community of Practice Leader the documentation of the review, model documentation, and a recommendation for or against certification/approval. CECW-P, in consultation with the Model Certification HQ Panel, will make the determination to certify/approve or not certify/approve the model. Upon certification/approval, CECW-P will issue a certification/approval memorandum and (for certified models) instruct the PCX to add the model to the National toolbox of certified models.

Response: The documentation has been submitted. Additional documentation describing the changes made and actions taken, along with the model code will be re-submitted as soon as it is available.

4. Documentation Provided by Proponent

Notification to DDPCX from CENWP-P	Attachment 4
MCR SRB Model Certification Memo	Attachment 5
Deep Draft PCX Approval for Use	Attachment 6

4.1. Model Technical Documentation

- **Calibration Results Documentation**

Moffat and Nichol, working with the PDT is currently reviewing the model calibration and will produce a calibration report with the PDT. Document will be available when received and approved. (see task 3 MCR MN SOW MOD2 attachment 3).

4.2. Model User Documentation

- The PDT and Moffat and Nichol are currently reviewing the model operations and establishing code that will allow the model to accept and produce input/output files. Upon completion of this task the Model User Guide will be updated and forwarded.

4.3. Model Support Literature

-

4.4. Model QA/QC Documentation/Activities

- Notification to DDPCX from CENWP-P — Attachment 4
- MCR SRB Model Certification Memo — Attachment 5
- Deep Draft PCX Approval for Use — Attachment 6

5. Type/Scope of Review

Per EC-1105-2-412, 31 March 2011, the PCX recommended an Extensive Review. The model is currently undergoing an extensive review and the PDT recommends continuing, but not re-initiating, this process

The following language defines the scope of the review and will be provided to the model reviewers:

5.1. Preliminary charge for reviewers of the MCR Stochastic Reliability Based Model

The initial charge given to the ATR review and IEPR review team is shown below. In addition to the underlying theory, conceptualization, and computational aspects of the model, reviewers are asked to comment on aspects of the model that potentially affect its usability and reliability as a potential producer of information to be used to influence planning decisions.

While the specific review questions included below were intended to prompt the reviewer for information specific to the efforts to Approve for Single Use, the reviewers were encouraged to offer comments believed relevant and appropriate to any elements of the technical quality and usability of the model, Major Rehab Report and appendices as documented in the provided review materials. Accordingly, please provide responses to the sought scientific and technical topics listed below and perform a broad review of the focusing on your areas of expertise, experience, and technical knowledge. Listed below are the model review charge questions.

IEPR Charge Questions relevant to the Model Provided by PDT

1. Is the purpose of the model clearly defined?

2. Is the model diagram easily understood.

3. Does the model follow a logical programming path.

4. Is the model free from programming errors that would alter the model results significantly enough to skew the plan selection?

5. Does the model adequately capture and evaluate all of the relevant variables.

6. Can the model described achieve the stated purpose?

7. Does the model accurately describe (model) repair activities and sequences? Is it modeling the repair activities similarly to how the repairs will be sequenced and performed.

Technical Quality

8. Comment on the overall technical quality of the model.

9. Is the model based on well-established contemporary theory?
    a. Is the available science applied correctly?
    b. Are the models empirically supported?

10. Is the model a realistic representation of the actual system?

11. Are the analytical requirements of the model properly identified?

12. Does the model address and properly incorporate the analytical requirements?

13. Are the assumptions clearly identified, valid, and do they support the analytical requirements?

14. Are the formulas used in the model mathematically correct and are the model computations appropriate and done correctly?

15. Comment on the ability of the model to address risk and uncertainty.

16. Comment on the ability of the modes to calculate benefits for total project life.

17. Does the model adequately assess the full range of costs associated with the three jetties?

18. Will the model be useful in capturing and quantifying the full extent of benefits expected to be obtained from anticipated repairs?

System Quality

19. Has the model been sufficiently tested and validated, or do critical errors still exist?

Usability

20. Comment on the models' usability.

21. Comment on the availability of the data required by the model.

22. How easily are model results understood?

23. Comment on how useful model results are for supporting project objectives.

24. Is user documentation available, user friendly, and complete?

25. Is the model transparent and does it allow for easy verification of calculations and outputs?

OTHER GENERAL QUESTIONS

26. Can the model be adapted to other geographic regions?
    a. If so, how much can the model be modified before they need to be reviewed again?

27. Is it clear where the model's geographic boundaries fall?

28. Is the approach to the development and use of the model described clearly enough to allow the approach to be repeated and obtain the same or similar results?
    a. If not, why?
    b. If not, what needs to be done to make the approach repeatable?

29. Comment on the ability of the model to calculate benefits for total project life.

30. Is the application of the model defensible?

31. Comment on whether there are any resolution issues with the model (i.e., size of the area that can effectively be evaluated).
    a. At what scale (e.g. acres, hundreds of acres) can the models be effectively applied?

32. Comment on whether all of the most important variables are included in the model.
    a. Are variables that are both stressors and drivers included in the model?
    b. Should additional variables be included?
    c. Are some of the variables more sensitive than others?

33. To what extent is best professional judgment used in the model?

34. To what extent is the model developed specifically for the MCR Jetties?

35. Are error checks built into the model?

36. Are USACE policies and procedures related to the model clearly identified?

37. Does the model properly incorporate USACE policies and accepted procedures?

38. Is sea level change addressed by the model?
    a. If yes, is it internal to the model or does it need to be addressed externally?

5.2 Follow-On review charge.

The reviewers will not be charged with initiating a new review of the product in its entirety. The reviewers are charged with reviewing the IEPR comments and responses, and the PDT's subsequent actions, edits and changes in order to confirm that the PDT has adequately addressed the IEPR panel's questions. Follow-up questions made by the reviewers will also be addressed by the PDT until the reviewers, and the PDC, are satisfied that all outstanding issues have been resolved.

6. DN**N-PCX Summary.**

The DDN-PCX will provide a summary of review findings, which will include a summary of comments, and a strategy for implementing any necessary actions to remedy any additional or remaining deficiencies. The DDN-PCX will close-out the review when it determines identified issues have been resolved to its satisfaction.

FINAL
INDEPENDENT EXTERNAL PEER REVIEW REPORT
for the

Columbia River at the Mouth, Oregon and Washington
Major Rehabilitation Evaluation Report

EXECUTIVE SUMMARY

Project Background and Purpose

The Mouth of the Columbia River (MCR) navigation project is located at the confluence of the Columbia River with the Pacific Ocean on the border between Washington and Oregon. Navigation is maintained by three primary navigation structures, North Jetty, South Jetty, and Jetty A. The North Jetty and Jetty A are located in Pacific County, Washington, near Ilwaco and Long Beach on the Long Beach Peninsula. The North Jetty was completed in 1917. Jetty A, positioned on the south side of the North Jetty, was constructed in 1939 to a length of 1.1 miles. Jetty A was constructed to direct river and tidal currents away from the North Jetty foundation. The South Jetty is located in Clatsop County, Oregon near Warrenton/Hammond and Astoria. The initial 4.5-mile section of the South Jetty was completed in 1895, with a 2.4-mile extension completed in 1913. Jetty construction realigned the ocean entrance to the Columbia River, established a consistent navigation channel that was 40 feet below MLLW across the bar, and significantly improved navigation through the MCR. Improvements made from 1930 to 1942 (including addition of Jetty A and Sand Island pile dikes) produced the present entrance configuration. Each year, ocean-going vessels on the Columbia River carry about 40 million tons of cargo with an estimated value of $17 billion on an annual basis. More than 12,000 commercial vessels and 100,000 recreational/charter vessels navigate through the MCR annually.

Prior to improvement in 1885, the tidal channels through the MCR shifted north and south between Fort Stevens and Cape Disappointment, a distance of about 5.5 miles. The controlling depth of dominant channel through the ebb tidal delta varied between 18 to 25 feet deep below MLLW. The ebb and flood tidal deltas at MCR entrance were distributed over a large area immediately seaward and upstream of the river mouth. Ships often had difficulty traversing the Columbia River bar, the area in which the flow of the estuary rushes headlong into towering ocean waves. On many occasions, outbound ships had to wait a month or more until bar conditions were favorable for crossing. To make navigating through the MCR even worse, sailing ships had to approach either of the two natural channels abeam to the wind and waves. The natural channels often shifted widely within the course of several tidal cycles. At best, crossing the bar was dangerous. At worst, it was not possible. Offshore of the MCR lies the vast expanse of the northeast Pacific Ocean. Inshore of the MCR lies the Columbia River and estuary, the coastal outlet for a drainage basin of 250,000 square miles.

Despite intermittent repair and partial rehabilitation efforts, all of the MCR jetties are currently in an unacceptably deteriorated condition. This project was undertaken to address problems related to the structural stability of the MCR jetty system in order to extend the functional life of the jetties and maintain deep-draft navigation.

Independent External Peer Review Process

USACE is conducting an Independent External Peer Review (IEPR) of the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report (hereinafter Mouth of Columbia River IEPR). Battelle, as a 501(c)(3) non-profit science and technology organization with experience in establishing and administering peer review panels for USACE, was engaged to coordinate the IEPR of the Mouth of Columbia River Major Rehabilitation Evaluation Report. Independent, objective peer review is regarded as a critical element in ensuring the reliability of scientific analyses. The IEPR was external to the agency and conducted following USACE and Office of Management and Budget (OMB) guidance described in USACE (2010), USACE (2007), and OMB (2004). This final report describes the IEPR process, describes the panel members and their selection, and summarizes the Final Panel Comments of the IEPR Panel (the Panel).

Five panel members were selected for the IEPR from more than 28 identified candidates. Based on the technical content of the Mouth of Columbia River Major Rehabilitation Evaluation Report and the overall scope of the project, the final panel members were selected for their technical expertise in the following key areas: design and construction engineering (coastal engineering), plan formulation, biology NEPA, hydrology and hydraulics engineering/coastal engineering, geomorphology, and economics. USACE was given the list of candidate panel members, but Battelle made the final selection of the Panel.

The Panel received electronic versions of the Mouth of Columbia River IEPR documents, totaling more than 1,000 pages, along with a charge that solicited comments on specific sections of the documents to be reviewed. The charge was prepared by USACE according to guidance provided in USACE (2010) and OMB (2004). Charge questions were provided by USACE and included in the draft and final Work Plans.

The USACE Project Delivery Team briefed the Panel and Battelle during a kick-off meeting held via teleconference prior to the start of the review. In addition to this initial teleconference, a second teleconference with USACE, the Panel, and Battelle was conducted halfway through the review period to provide the Panel an opportunity to ask questions of USACE and clarify uncertainties. The Panel produced more than 500 individual comments in response to the 78 charge questions.

IEPR panel members reviewed the Mouth of Columbia River IEPR documents individually. The panel members then met via teleconference with Battelle to review key technical comments, discuss charge questions for which there were conflicting responses, and reach agreement on the Final Panel Comments to be provided to USACE. Each Final Panel Comment was documented using a four-part format consisting of: (1) a comment statement; (2) the basis for the comment; (3) the significance of the comment (high, medium, or low); and (4) recommendations on how to resolve the comment. Overall, 25 Final Panel Comments were developed. Of these, 8 were identified as having high significance, 14 had medium significance, and 3 had low significance.

Results of the Independent External Peer Review

The panel members agreed among one another on their "assessment of the adequacy and acceptability of the economic, engineering, and environmental methods, models, and analyses used" (USACE, 2010; p. D-4) in the Mouth of Columbia River IEPR document. Of primary significance, and as discussed in several of the Final Panel Comments, the Panel has serious concern with the SRB model and the potentially over-emphasized role it played in the evaluation of alternatives, engineering design, and economic analyses. Table ES-1 lists the Final Panel Comments statements by level of significance. The full text of the Final Panel Comments is presented in Appendix A of this report. The following statements summarize the Panel's findings.

Plan Formulation Rationale: From a planning perspective, the Major Rehabilitation Evaluation Report is well done and in compliance with all of the typical formulation steps; however, it was never clearly explained that the scope of work was limited to the repair and rehabilitation within the present configuration, nor why it was limited in this manner. Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected. The Panel agreed that the SRB model is not a substitute for conventional engineering and economic analyses and should not be a stand-alone analysis for selecting a recommended plan.

Economics: The Panel identified three major issues in the economic analysis: (1) inconsistencies in the Major Rehabilitation Evaluation Report and economic spreadsheet models; (2) the assumption that navigation would not be impacted; and (3) the formulation of the base condition. Inconsistencies in the report and economic spreadsheet models pertaining to the calculation of NPVs and AACs prevented the Panel from validating the economic analysis. Based on the assumption that navigation will not be impacted, a least cost analysis was used in lieu of a transportation cost savings analysis to calculate NED benefits. Conflicting assumptions concerning the ability to maintain navigation invalidate the logic behind calculating NED benefits using a least cost analysis. As the project is currently formulated, the base condition maintenance strategy for the MCR jetties conforms most closely with the fix-as-fails strategy, while the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits. Each of these issues could impact the selection of the NED plan, which was selected as the recommended plan.

Engineering: There are serious technical difficulties with the Major Rehabilitation Evaluation Report and analyses. The report lacks a set of design criteria, including project life, standards of performance to be met, and environmental conditions with return period events. All are part of conventional coastal engineering design practice. The SRB model cannot be verified and does not include important processes. Major questions remain that have not been adequately investigated for this level of study, including subsurface geotechnical properties, feasibility of proposed barge offloading/material re-handling facilities, and the long term stability of the jetty foundations assuming continued erosion and loss of nearshore sediment. The report indicates that large volumes of sediment will move into the navigation channel after a breach event. However, the data and analysis do not support this conclusion. Additionally, is no clear discussion of the role of maintenance or emergency dredging, especially under extreme winter conditions. Detailed construction cost estimates also need to be provided in order for the cost analysis to be complete and verifiable. Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition.

Environmental: There is no discussion in the main report of sea level rise and potential wave height increases and its impact on this project over the 50+ year project timeline, given that the regional wave climate has been documented as more severe in the last 10 years. This has potential impacts to the project and in designing a project with lower long-term maintenance costs. Potential environmental impacts on sensitive species, upland habitats, and water quality as well as potential impacts to recreational use during project construction are not comprehensive nor adequately described in the mitigation plan. Finally, the alternatives are limited to armoring the existing configuration of the jetties and may not satisfy NEPA directive for alternative analysis.

Table ES-1. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel

Significance – High	
1	The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.
2	The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.
3	The underlying assumption that navigational impacts will not occur is not substantiated.
4	The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
5	The base condition, as formulated, does not represent the current O&M practice.
6	The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
7	The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.
8	The models and analyses of jetty failure do not include all significant processes.
Significance – Medium	
9	The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
10	A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
11	Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.

Table ES–1. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel, continued

Significance – Medium	
12	Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.
13	Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.
14	Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.
15	There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.
16	The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.
17	The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
18	The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.
19	Risk thresholds for selected alternatives are not clearly defined.
20	It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
21	The model output parameters and wave height components are not clearly explained and supported.
22	The culvert installation details, as well as potential impacts, need further clarification.
Significance – Low	
23	The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
24	Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.
25	Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.

1. INTRODUCTION

The Mouth of the Columbia River (MCR) navigation project is located at the confluence of the Columbia River with the Pacific Ocean, on the border between Washington and Oregon. Navigation is enabled by three primary navigation structures, North Jetty, South Jetty, and Jetty A, plus maintenance dredging of about 4 million cubic yards per year from the entrance channel. The North Jetty and Jetty A are located in Pacific County, Washington, near Ilwaco and Long Beach on the Long Beach Peninsula. The North Jetty was completed in 1917. Jetty A, positioned on the south side of the North Jetty, was constructed in 1939 to a length of 1.1 miles. Jetty A was constructed to direct river and tidal currents away from the North Jetty foundation. The South Jetty is located in Clatsop County, Oregon near Warrenton/Hammond and Astoria. The initial 4.5-mile section of the South Jetty was completed in 1895, with a 2.4-mile extension completed in 1913. Jetty construction realigned the ocean entrance to the Columbia River, established a consistent navigation channel that was 40 feet below mean lower low water (MLLW) across the bar, and significantly improved navigation through the MCR. Improvements made from 1930 to 1942 (including addition of Jetty A and Sand Island pile dikes) produced the present entrance configuration.

Prior to improvement in 1885, the tidal channels through the MCR shifted north and south between Fort Stevens and Cape Disappointment, a distance of about 5.5 miles. The controlling depth of dominant channel through the ebb tidal delta varied between 18 to 25 feet deep below MLLW. The ebb and flood tidal deltas at MCR entrance were distributed over a large area immediately seaward and upstream of the river mouth. Ships often had difficulty traversing the Columbia River bar, the area in which the flow of the estuary rushes headlong into towering ocean waves. On many occasions, outbound ships had to wait a month or more until bar conditions were favorable for crossing. To make navigating through the MCR even worse, sailing ships had to approach either of the two natural channels abeam to the wind and waves. The natural channels often shifted widely within the course of several tidal cycles. At best, crossing the bar was dangerous. At worst, it was not possible. Offshore of the MCR lies the vast expanse of the northeast Pacific Ocean. Inshore of the MCR lies the Columbia River and estuary, the coastal outlet for a drainage basin of 250,000 square miles.

The objective of the work described here was to conduct an Independent External Peer Review (IEPR) of the Mouth of Columbia River Major Rehabilitation Evaluation Report in accordance with procedures described in the Department of the Army, U.S. Army Corps of Engineers (USACE) Engineer Circular *Civil Works Review Policy* (EC No. 1165-2-209) (USACE, 2010), USACE CECW-CP memorandum *Peer Review Process* (USACE, 2007), and Office of Management and Budget (OMB) bulletin *Final Information Quality Bulletin for Peer Review* (OMB, 2004). Battelle, as a 501(c)(3) non-profit science and technology organization with experience in establishing and administering peer review panels, was engaged to coordinate the IEPR of the Mouth of Columbia River Major Rehabilitation Evaluation Report. Independent, objective peer review is regarded as a critical element in ensuring the reliability of scientific analyses.

This final report details the IEPR process, describes the IEPR panel members and their selection, and summarizes the Final Panel Comments of the IEPR Panel on the existing environmental, economic, and engineering analyses contained in the Mouth of Columbia River Major Rehabilitation Evaluation Report. The full text of the Final Panel Comments is presented in Appendix A.

2. PURPOSE OF THE IEPR

To ensure that USACE documents are supported by the best scientific and technical information, USACE has implemented a peer review process that uses IEPR to complement the Agency Technical Review (ATR), as described in USACE (2010) and USACE (2007).

In general, the purpose of peer review is to strengthen the quality and credibility of the USACE decision documents in support of its Civil Works program. IEPR provides an independent assessment of the economic, plan formulation, engineering, and environmental analysis of the project study. In particular, the IEPR addresses the technical soundness of the project study's assumptions, methods, analyses, and calculations and identifies the need for additional data or analyses to make a good decision regarding implementation of alternatives and recommendations.

In this case, the IEPR of the Mouth of Columbia River Major Rehabilitation Evaluation Report was conducted and managed using contract support from Battelle, which is an Outside Eligible Organization under Section 501(c)(3) of the U.S. Internal Revenue Code with experience conducting IEPRs for USACE.

3. METHODS

This section describes the method followed in selecting the members for the IEPR Panel (the Panel) and in planning and conducting the IEPR. The IEPR was conducted following procedures described by USACE (2010) and in accordance with USACE (2007) and OMB (2004) guidance. Supplemental guidance on evaluation for conflicts of interest (COIs) was obtained from the *Policy on Committee Composition and Balance and Conflicts of Interest for Committees Used in the Development of Reports* (The National Academies, 2003).

3.1 Planning and Schedule

After receiving the notice to proceed (NTP), Battelle held a kick-off meeting with USACE to review the preliminary/suggested schedule, discuss the IEPR process, and address any questions regarding the scope (e.g., clarify expertise areas needed for panel members). Any revisions to the schedule were submitted as part of the final Work Plan.

Table 1 defines the schedule followed in executing the IEPR. Due dates for milestones and deliverables are based on the NTP date of December 6, 2010. Note that the work items listed in Task 7 occur after the submission of this report. Battelle will enter the 25 Final Panel Comments developed by the Panel into USACE's Design Review and Checking System (DrChecks), a Web-based software system for documenting and sharing comments on reports and design documents, so that USACE can review and respond to them. USACE will provide responses (Evaluator Responses) to the Final Panel Comments, and the Panel will respond (BackCheck Responses) to the Evaluator Responses. All USACE and Panel responses will be documented by Battelle.

Table 1. Mouth of Columbia River IEPR Schedule

TASK	ACTION	DUE DATE
1	**NTP**	12/6/2010
	Review documents available	12/7/2010
	[a]Battelle submits draft Work Plan	12/15/2010
	USACE provides comments on draft Work Plan	12/20/2010
	[a]Battelle submits final Work Plan	12/28/2010
2	Battelle requests input from USACE on the conflict of interest (COI) questionnaire	12/8/2010
	USACE provides comments on COI questionnaire	12/9/2010
	[a]Battelle submits list of selected panel members	12/16/2010
	USACE provides comments on selected panel members	12/17/2010
	Battelle completes subcontracts for panel members	1/5/2011
3	[a]Battelle receives final charge from USACE (to be included in Work Plan)	12/10/2010
4	USACE/Battelle kick-off meeting	12/13/2010
	Battelle sends review documents to IEPR Panel	1/6/2011
	USACE/Battelle/Panel kick-off meeting	1/7/2011
	Battelle convenes mid-review teleconference for panel to ask clarifying questions of USACE	1/19/2011
5	Panel members complete their individual reviews	1/31/2011
	Battelle convenes panel review teleconference with IEPR Panel	2/10-2/11/2011
	Panel members provide draft Final Panel Comments to Battelle	2/21/2011
6	[a]Battelle submits Final IEPR Report to USACE	3/9/2011
7[b]	Battelle inputs Final Panel Comments to DrChecks; Battelle provides Final Panel Comment response template to USACE	3/10/2011
	Battelle convenes teleconference with USACE to review the requirements of the Evaluator Response process.	3/11/2011
	USACE provides draft Evaluator Responses and clarifying questions to Battelle	3/16/2011
	Battelle convenes teleconference between Battelle, Panel, and USACE to discuss Final Panel Comments, draft responses, and clarifying questions	3/23/2011
	USACE inputs final Evaluator Responses in DrChecks	3/30/2011
	Battelle inputs the Panel's BackCheck Responses in DrChecks	4/7/2011
	[a]Battelle submits pdf printout of DrChecks project file	4/8/2011
	Project Closeout	6/13/2011

[a] Deliverable

[b] Task 7 occurs after the submission of this report.

3.2 Identification and Selection of IEPR Panel Members

The candidates for the Panel were evaluated based on their technical expertise in the following key areas: design and construction engineering (coastal engineering), plan formulation, biology/ National Environmental Policy Act (NEPA), hydrology and hydraulics engineering/coastal engineering, geomorphology, and economics. These areas correspond to the technical content of the Mouth of Columbia River IEPR and overall scope of the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report project.

To identify candidate panel members, Battelle reviewed the credentials of the experts in Battelle's Peer Reviewer Database, sought recommendations from colleagues, contacted former panel members, and conducted targeted Internet searches. Battelle initially identified more than 28 candidates for the Panel, evaluated their technical expertise, and inquired about potential COIs. Of these, Battelle chose seven of the most qualified candidates and confirmed their interest and availability. Of the seven candidates, five were proposed for the final Panel and two were proposed as backup reviewers. Information about the candidate panel members, including brief biographical information, highest level of education attained, and years of experience, was provided to USACE for feedback. Battelle made the final selection of panel members according to the selection criteria described in the Work Plan.

The five proposed primary reviewers constituted the final Panel. The remaining candidates were not proposed for a variety of reasons, including lack of availability, disclosed COIs, or lack of the precise technical expertise required.

The candidates were screened for the following potential exclusion criteria or COIs.[1] These COI questions were intended to serve as a means of disclosure and to better characterize a candidate's employment history and background. Providing a positive response to a COI screening question did not automatically preclude a candidate from serving on the Panel. For example, participation in previous USACE technical peer review committees and other technical review panel experience was included as a COI screening question. A positive response to this question could be considered a benefit.

- Involvement by you or your firm[2] in the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Involvement by you or your firm[2] in any work related to deep draft navigation studies on the Columbia River.

---

[1] Battelle evaluated whether scientists in universities and consulting firms that are receiving USACE-funding have sufficient independence from USACE to be appropriate peer reviewers. See OMB (2004, p. 18), "….when a scientist is awarded a government research grant through an investigator-initiated, peer-reviewed competition, there generally should be no question as to that scientist's ability to offer independent scientific advice to the agency on other projects. This contrasts, for example, to a situation in which a scientist has a consulting or contractual arrangement with the agency or office sponsoring a peer review. Likewise, when the agency and a researcher work together (e.g., through a cooperative agreement) to design or implement a study, there is less independence from the agency. Furthermore, if a scientist has repeatedly served as a reviewer for the same agency, some may question whether that scientist is sufficiently independent from the agency to be employed as a peer reviewer on agency-sponsored projects."

- Involvement by you or your firm[2] in projects related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Involvement by you or your firm[2] in the conceptual or actual design, construction, or O&M of any projects related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Current employment by the U.S. Army Corps of Engineers (USACE).
- Involvement with paid or unpaid expert testimony related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Current or previous employment or affiliation with members of any of the following cooperating Federal, State, County, local and regional agencies, environmental organizations, and interested groups: National Marine Fisheries Service, U.S. Fish and Wildlife Service, U.S. Geological Survey, Washington Department of Ecology, Oregon Department of Environmental Quality, Oregon Department of Land Conservation and Development, or Portland State University (for pay or pro bono).
- Past, current or future interests or involvements (financial or otherwise) by you, your spouse or children related to the mouth of the Columbia River.
- Current personal involvement with other USACE projects, including whether involvement was to author any manuals or guidance documents for USACE. If yes, provide titles of documents or description of project, dates, and location (USACE district, division, Headquarters, ERDC, etc.), and position/role. Please highlight and discuss in greater detail any projects that are specifically with the Portland District.
- Current firm[2] involvement with other USACE projects, specifically those projects/contracts that are with the Portland District. If yes, provide title/description, dates, and location (USACE district, division, Headquarters, ERDC, etc.), and position/role.
- Any previous employment by the USACE as a direct employee or contractor (either as an individual or through your firm[2]) within the last 10 years, notably if those projects/contracts are with the Portland District. If yes, provide title/description, dates employed, and place of employment (district, division, Headquarters, ERDC, etc.), and position/role.
- Previous experience conducting technical peer reviews. If yes, please highlight and discuss any technical reviews concerning deep draft navigation or coastal engineering, and include the client/agency and duration of review (approximate dates).
- Pending, current or future financial interests in contracts/awards from USACE related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- A significant portion (i.e., greater than 50%) of personal or firm[2] revenues within the last 3 years came from USACE contracts.
- Any publicly documented statement (including, for example, advocating for or discouraging against) related to Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.

- Participation in relevant prior Federal studies relevant to this project, including:
  - U.S. Army Corps of Engineers. 1983. Columbia River at the Mouth Navigation Channel Improvement, Final Environmental Impact Statement, Oregon-Washington. Portland, Oregon.
  - Earth Sciences Associates and Geo Recon International. 1985. Geologic and Seismic Investigation of Columbia River Mouth Study Area, Report for U.S. Army Corps of Engineers, Portland District, Portland, Oregon.
  - Northwest Geophysical Associates, Inc. 1996. 1996 Columbia River Offshore Disposal Site Study, Sidescan Sonar Investigation, Report for U.S. Army Corps of Engineers, Portland District, Portland, Oregon.
  - U.S. Army Corps of Engineers. 1999. Integrated Feasibility Report for Channel Improvements and Environmental Impact Statement, Columbia and Lower Willamette River Federal Navigation Channel. Portland, Oregon.
  - NMFS. 2004. Endangered Species Act Section 7 Formal Consultation and Magnuson-Stevens Fishery and Conservation Management Act Essential Fish Habitat Consultation for the Columbia River North and South Jetties Rehabilitation, Columbia River Basin, Clatsop County, Oregon.
  - USACE. 2005. Interim Repair Decision Document for North and South Jetties at the Mouth of the Columbia River, Oregon and Washington. U.S. Army Corps of Engineers-Portland District, Portland, Oregon.
  - Global Remote Sensing. 2005. Mouth of the Columbia River Offshore Disposal Site Study, Multibeam Investigations, Report for U.S. Army Corps of Engineers, Portland District, Portland, Oregon.
  - Tetra Tech, Inc. April 2007. Wetland and Waters of the U.S. Delineation Revised Final Report: North Jetty, Mouth of the Columbia River, Pacific County, Washington. Prepared for U.S. Army Corps of Engineers, Portland, Oregon.
  - Tetra Tech, Inc. April 2007. Clatsop Spit Plant Communities Investigation and Mapping, Final Report: South Jetty, Mouth of the Columbia River, Clatsop County, Oregon. Prepared for U.S. Army Corps of Engineers, Portland, Oregon.
  - Ward, D. L., Melby, J.A., Myrick, G.B., and Henderson, W.G. 2007. Physical Model Study of Jetties at the Mouth of the Columbia River, Oregon and Washington. ERDC/CHL TR-07-XX.   - Demirbilik, Z., Lin, L, and Nwogu, O.G. 2008. Wave Modeling for Jetty Rehabilitation at the Mouth of the Columbia River, Oregon and Washington. ERDC/CHL TR-08-3. U.S. Army Corps of Engineers. Engineer Research and Development Center-Coastal and Hydraulics Laboratory. Vicksburg, Mississippi.
  - Moritz, H.R. and Moritz, H. P. 2009. Stochastic Risk-Based Life Cycle Simulation of Century Old Jetties at the Mouth of the Columbia River, USA. International Conference on Coasts, Marine Structures, and Breakwaters 2009. Proceedings of the Institution of Civil Engineers. Presented in Edinburgh, Scotland, September 2009.
- Participation in prior non-Federal studies relevant to this project.

- Is there any past, present or future activity, relationship or interest (financial or otherwise) that could make it appear that you would be unable to provide unbiased services on this project? If so, please describe:

In selecting the final members of the Panel from the list of candidates, Battelle chose experts who best fit the expertise areas and had no COIs. The five final reviewers were either affiliated with academic institutions or consulting companies or were independent engineering consultants. Battelle established subcontracts with the panel members when they indicated their willingness to participate and confirmed the absence of COIs through a signed COI form. USACE was given the list of candidate panel members, but Battelle made the final selections of the Panel. Section 4 of this report provides names and biographical information on the panel members.

Prior to beginning their review and within 2 days of their subcontracts being finalized, all members of the Panel attended a kick-off meeting via teleconference planned and facilitated by Battelle in order to review the IEPR process, the schedule, communication procedures, and other pertinent information for the Panel.

3.3 Preparation of the Charge and Conduct of the IEPR

Shortly after Battelle received NTP, USACE provided the following documents and reference materials. The documents and files in bold font were provided for review and the other documents were provided for reference or supplemental information only.

- **Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report**
  - **Appendix A1: Coastal Engineering**
  - **Appendix A2: Reliability Analysis, Event Tree Formulation and Life-Cycle Simulation**
  - **Appendix B: Geotechnical**
  - **Appendix C: Economics**
  - **Appendix D: Environmental Documentation**
  - **Appendix E: M-CACES Cost Estimate for Recommended Plan**
  - Appendix F: Project Management Plan
  - Appendix G: Schedule of Fully Funded Project Costs
- USACE guidance *Civil Works Review Policy* (EC 1165-2-209) dated January 31, 2010
- CECW-CP Memorandum dated March 31, 2007
- Office of Management and Budget's *Final Information Quality Bulletin for Peer Review* released December 16, 2004.

In addition, throughout the review period, USACE provided additional documents at the request of panel members. These additional documents were provided as supplemental information only and were not part of the official review:

- Jetty Rehab, Mouth of the Columbia River, USGS Draft v01 Appendix Figures, Edwin Elias and Guy Gelfenbaum 2007
- Jetty Rehab, Mouth of the Columbia River, USGS Draft v02, Edwin Elias and Guy Gelfenbaum 2007

- Analysis of Jetty Rehabilitation at the Mouth of the Columbia River, Washington/Oregon, USA Part: 2 Regional Circulation, Sediment Transport, and Morphology Change June 2007 ERDC/CHL Kenneth J. Connell and Julie Dean Rosati
- 2009 MCR Jetty inspection reports and supporting documentation
- Summary of the Jetty heads and the physical model
- Model Documentation Report
- Additional documentation on design criteria
- Appendix b geotechnical studies (as listed in the file name)
- Exhibit M Economic Analysis of the Columbia River Channel Improvement Project, Final Supplemental Integrated Feasibility Report and Environmental Impact Statement
- Economic spreadsheet models for each jetty
- Three AVIs and videos showing the velocity vectors at the MCR
- a summary of the Jetty heads and the physical model
- Mouth of the Columbia River North Jetty, South Jetty, and Jetty A Rehabilitation Template Examples
- Documentation sent to USACE Headquarters to obtain model approval for use.

Charge questions were provided by USACE and included in the draft and final Work Plans. In addition to a list of 78 charge questions/discussion points, the final charge included general guidance for the Panel on the conduct of the peer review (provided in Appendix B of this final report).

Battelle planned and facilitated a final kick-off meeting via teleconference during which USACE presented project details to the Panel. Before the meeting, the IEPR Panel received an electronic version of the Mouth of Columbia River IEPR documents and the final charge. A full list of the documents reviewed by the Panel is provided in Appendix B of this report. The Panel was instructed to address the charge questions/discussion points within a comment-response form provided by Battelle.

3.4 Review of Individual Comments

Prior to completion of the review of the Mouth of Columbia River IEPR documents, a teleconference with USACE, the Panel, and Battelle was held halfway through the review period to provide the Panel an opportunity to ask questions of USACE regarding uncertainties requiring clarification. At the end of the review period, the Panel produced approximately 500 individual comments in response to the charge questions/discussion points. Battelle reviewed the comments to identify overall recurring themes, areas of potential conflict, and other overall impressions. As a result of the review, Battelle summarized the 500 comments into a preliminary list of 44 overall comments and discussion points. Each panel member's individual comments were shared with the full Panel in a merged individual comments table.

3.5 IEPR Panel Teleconference

Due to the number of comments and the complexity of the issues, Battelle facilitated two 3-hour teleconferences with the Panel so that the panel members, many of whom are from diverse scientific backgrounds, could exchange technical information. The main goal of the teleconferences was to identify which issues should be carried forward as Final Panel Comments in the IEPR report and decide which panel member would serve as the lead author for the development of each Final Panel Comment. This information exchange ensured that the Final IEPR Report would accurately represent the Panel's assessment of the project, including any conflicting opinions. The Panel engaged in a thorough discussion of the overall positive and negative comments, added any missing issues of high-level importance to the findings, and merged any related individual comments. In addition, Battelle confirmed each Final Panel Comment's level of significance to the Panel.

The Panel also discussed responses to seven specific charge questions where there appeared to be disagreement among panel members. The conflicting comments were resolved based on the professional judgment of the Panel, and each comment was either incorporated into a Final Panel Comment, determined to be consistent with other Final Panel Comments already developed, or determined to be a non-significant issue.

At the end of these discussions, the Panel identified 30 initial comments and discussion points that should be brought forward as Final Panel Comments.

3.6 Preparation of Final Panel Comments

Following the teleconference, Battelle prepared a summary memorandum for the Panel documenting each Final Panel Comment (organized by level of significance). The memorandum provided the following detailed guidance on the approach and format to be used to develop the Final Panel Comments for the Mouth of Columbia River IEPR:

- Lead Responsibility: For each Final Panel Comment, one Panel member was identified as the lead author responsible for coordinating the development of the Final Panel Comment and submitting it to Battelle. Battelle modified lead assignments at the direction of the Panel. To assist each lead in the development of the Final Panel Comments, Battelle distributed the merged individual comments table, a summary detailing each draft final comment statement, an example Final Panel Comment following the four-part structure described below, and templates for the preparation of each Final Panel Comment.
- Directive to the Lead: Each lead was encouraged to communicate directly with other IEPR panel members as needed and to contribute to a particular Final Panel Comment. If a significant comment was identified that was not covered by one of the original Final Panel Comments, the appropriate lead was instructed to draft a new Final Panel Comment.
- Format for Final Panel Comments: Each Final Panel Comment was presented as part of a four-part structure:
    1. Comment Statement (succinct summary statement of concern)
    2. Basis for Comment (details regarding the concern)
    3. Significance (high, medium, low; see description below)
    4. Recommendation(s) for Resolution (see description below).
- Criteria for Significance: The following were used as criteria for assigning a significance level to each Final Panel Comment:

1. High: Describes a fundamental problem with the project that could affect the recommendation, success, or justification of the project. Comments rated as high indicate that the Panel analyzed or assessed the methods, models, and/or analyses and determined that there is a "showstopper" issue.
2. Medium: Affects the completeness of the report in describing the project, but will not affect the recommendation or justification of the project. Comments rated as medium indicate that the Panel does not have sufficient information to analyze or assess the methods, models, or analyses.
3. Low**:** Affects the understanding or accuracy of the project as described in the report, but will not affect the recommendation or justification of the project. Comments rated as low indicate that the Panel identified information (tables, figures, equations, discussions) that was mislabeled or incorrect or data or report sections that were not clearly described or presented.

- Guidance for Developing Recommendation: The recommendation section was to include specific actions that USACE should consider to resolve the Final Panel Comment (e.g., suggestions on how and where to incorporate data into the analysis, how and where to address insufficiencies, areas where additional documentation is needed).

Battelle reviewed and edited the Final Panel Comments for clarity, consistency with the comment statement, and adherence to guidance on the Panel's overall charge, which included ensuring that there were no comments regarding either the appropriateness of the selected alternative or USACE policy. At the end of this process, 25 Final Panel Comments were prepared and assembled; four of the original 30 comments were merged with other existing Final Panel Comments and one was deleted because it did not meet the criteria for significance for Final Panel Comments. There was no direct communication between the Panel and USACE during the preparation of the Final Panel Comments; however, Battelle sent working drafts of the Final Panel Comments to USACE as a means to help them get a head start in providing responses to the Panel comments. Battelle informed USACE that these working drafts could be revised, merged, deleted, or new comments created prior to the submittal of the Final IEPR Report. The Final Panel Comments are presented in Appendix A of this report.

4. PANEL DESCRIPTION

Candidates for the Panel were identified using Battelle's Peer Reviewer Database, targeted Internet searches using key words (e.g., technical area, geographic region), searches of websites of universities or other compiled expert sites, and referrals. Battelle prepared a draft list of primary and backup candidate panel members (who were screened for availability, technical background, and COIs), and provided it to USACE for feedback. Battelle made the final selection of panel members.

An overview of the credentials of the final five primary members of the Panel and their qualifications in relation to the technical evaluation criteria is presented in Table 2. More detailed biographical information regarding each panel member and his or her area of technical expertise is presented in the text that follows the table.

Table 2. Mouth of Columbia River IEPR Panel: Technical Criteria and Areas of Expertise

	Phillips	Cuba	Rein	Sultan	Maher	Sultan
Civil Design/Construction [Coastal Engineering] (one expert needed)	**X**					
Minimum 10 years experience in civil design/construction and coastal engineering	X			X		X
Familiar with large, complex Civil Works projects with high public and interagency interests	X			X		X
Experience performing coastal engineering design and construction management for coastal projects	X			X		X
Familiar with similar projects across the United States and related coastal engineering	X			X		X
Experience in computer modeling including Matlab experience in coastal engineering	X			X		X
Familiar with construction industry and practices used in coastal construction in the Pacific Northwest	X			X		X
Degree in civil engineering	X			X		X
Plan Formulation (one expert needed)		**X**				
Minimum 10 years experience in the plan formulation process		X		X		X
Familiar with large, complex Civil Works projects with high public and interagency interests		X		X		X
Familiar with evaluation of alternative plans for coastal projects		X		X		X
Familiar with USACE standards and procedures		X		X		X
Degree in planning or a related field		See waiver*				
Biology NEPA (one expert needed)			**X**			
Minimum 10 years experience in biology		X	X			
Familiar with large, complex Civil Works projects with high public and interagency interests		X	X			
Particular knowledge of ecosystem restoration		X	X			
Familiar with all NEPA requirements		X	X			
Minimum of an M.S. degree in Biology		X	X			
Hydrology and Hydraulics Engineering/Coastal				**X**		

	Phillips	Cuba	Rein	Sultan	Maher	Sultan
Engineering (one expert needed)						
Minimum 10 years experience in hydrology and hydraulics engineering				X		X
Familiar with large, complex Civil Works projects with high public and interagency interests				X		X
Experience with sediment transport and engineering analyses related to design to include a variety of materials and cross-sections				X		X
Familiar with standard USACE hydrologic and hydraulic computer models used in jetty design				X		X
Minimum of an M.S. degree in civil engineering or hydrology and hydraulics				X		X
Registered professional engineer				X		X
Economics (one expert needed)					**X**	
Minimum 10 years experience in economics				X	X	X
Familiar with large, complex Civil Works projects with high public and interagency interests				X	X	X
Able to evaluate the appropriateness of cost effectiveness and incremental cost analysis (CE/ICA), as applied to USACE projects				X	X	X
Experience with National Economic Development (NED) analysis procedures, particularly as they relate to jetty construction projects					X	
Degree in economics or related field				X	X	X
Geomorphology (one expert needed)						**X**
Minimum 10 years experience in geomorphology				X		X
Familiar with large, complex Civil Works projects with high public and interagency interests				X		X
Experience with geological analyses related to project design to include a variety of materials and cross-sections used in jetty design				X		X
Minimum M.S. degree in civil engineering or geology				X		X
Registered professional engineer				X		X

* Dr. Tom Cuba has 28 years of experience in planning and biology/ecology. Dr. Cuba does not have his degree in planning or a related field. He has his Ph.D. in marine science/ecology. Battelle believes that his planning experience is commensurate with a degree in planning.

Shane Phillips, P.E.

Role: This panel member was chosen primarily for his coastal engineering design and construction management for coastal projects experience and expertise.
Affiliation: Coast and Harbor Engineering, Inc.

Shane Phillips, **P.E.,** a principal civil engineer at Coast and Harbor Engineering, Inc. in Edmonds, Washington, has 17 years of experience in marine and coastal engineering. He earned his B.S. in civil engineering in 1993 from Washington State University and is a registered professional engineer in Washington, California, Texas, Louisiana, and Florida. His specific engineering experience includes the feasibility evaluation, preliminary design, and final design of geotechnical, structural, and civil components of coastal and marine construction projects.

Mr. Phillips has applied his coastal engineering design expertise to a variety of coastal shore protection projects along the Pacific Northwest coast and has served as both on-site resident engineer and project manager on coastal construction projects including jetty, revetments, levees, dredging, and boating facilities. He served as project and design engineer for the North Jetty Beachfront Properties Coastal Erosion project in Ocean Shores, Washington, which involved the design and construction of a 1,000 foot long rock revetment structure.

Mr. Phillips has managed and executed feasibility studies, planning studies, and engineering of coastal and marine construction projects for port facilities, marinas, boating facilities, ferry terminals, marine terminals, navigation channels, and shoreline properties. He was Project Engineer for preliminary and final engineering design phase on the Willapa Bay, Washington SR-105 Emergency Stabilization Project consisting of a 1,400 foot long rock groin, 1,200 foot long submerged rock jetty and 1,100 feet of beach nourishment.

Coastal design experience includes the layout and design of floating breakwaters, groins, piers, bulkheads, beach nourishment, shoreline stabilization, dredging, water quality improvement, and nearshore restoration. Structural design experience includes the evaluation and engineering design of marine terminals, piers, bulkheads, retaining walls, breakwaters, and marinas using concrete, steel, and timber materials. Mr. Phillips has reviewed/verified computer modeling preparation and calibration and regularly works with engineering programs including AutoCad 2010, PCSTBLE, ACES, Surfer, SMS, Matlab, and Land Development.

Tom Cuba, Ph.D.

Role: This panel member was chosen primarily for his experience and expertise in the coastal plan formulation process.
Affiliation: Delta Seven, Inc.

Thomas R. Cuba, Ph.D., CEP, President and Chief Scientist at Delta Seven, Inc., serves as a Research Scientist at Stillwater Research Group, and is a research adjunct professor at the University of South Florida. He earned his Ph.D. in marine ecology from the University of South Florida in 1984. Dr. Cuba has 28 years of planning experience, which includes developing management plans for a variety of Florida watersheds and aquatic preserves, working on waterfront infrastructure feasibility plans, and designing wetland, pond, and seagrass restoration plans. Dr.Cuba’s six-year service as a Naval Intelligence Officer included plan formulation responsibilities, and he has been involved in civil and governmental plan formulation of engineered ecological restoration projects since 1984. Additionally, he conducted comprehensive conservation and public works plan formulation for Pinellas County, Florida and subsequently worked to enact these plans through public projects and codification in county ordinances.

Dr. Cuba has served as project manager and chief scientist on several watershed-based management and restoration projects (all of which included construction elements) and, for many of these, he acted as chair of the multi-stakeholder board. Dr. Cuba has assessed alternatives in beach nourishment and the placement of jetties and groins during his work with Pinellas County and in private practice. He is familiar with USACE plan formulation standards and procedures and has served on four USACE IEPR panels in the recent past as plan formulator (Clear Creek, C-111, Tamiami Trail, and LCA6).

Felicia Orah Rein, Ph.D.

Role: This panel member was chosen primarily for her biology/NEPA experience and expertise.
Affiliation: Watershed Solutions, Inc. and Florida Atlantic University

Felicia Orah Rein, Ph.D., is president and senior scientist at Watershed Solutions, Inc., an environmental consulting and restoration services firm specializing in environmental restoration, environmental assessments and impact analyses, ecological monitoring, water resource management, and reduction of sediment transport and erosion. She is also an affiliate professor at Florida Atlantic University. She earned her Ph.D. in ecosystem science/restoration ecology from the University of California at Santa Cruz in 2000 and has more than 20 years of experience managing and implementing large-scale multidisciplinary restoration ecology and resource protection projects.

Dr. Rein has extensive experience with large complex Civil Works projects with high public visibility, including assessment of environmental impacts of the New York/New Jersey Harbor deepening project for which she provided expertise in dredged material beneficial uses and source reduction and conducted vegetation and wetland mapping on coastal sites. Her NEPA expertise has involved collaboration with the National Marine Fisheries Service, California Department of Fish and Game, California State Water Resource Control Board, and U.S. Fish and Wildlife Service. She has a strong knowledge of ecosystem restoration, having worked on projects such as the Far Rockaway, Averne site park and housing development projects. Her role included wetland restoration areas and focused on water quality and vegetation impacts. Dr. Rein has prepared numerous Phase I (NEPA) environmental site assessments and is familiar with all NEPA requirements. As a senior project manager, she has provided scientific expertise on environmental documents according to NEPA guidelines and worked closely with local, state, and Federal government, as well as lawyers, environmentalists, and community groups on complex water rights assessments. She has experience in wetland ecology of urban regions, having worked in the initial phases of the fast-tracked wetland restoration projects in the NY/NJ region, including the hydrologic restoration of Liberty State Park and others.

She has conducted technical peer reviews, quality assurance/quality control (QA/QC) reviews, and acted as an expert consultant in environmental damage disputes for engineering and consulting firms. Dr. Rein is a member of Sigma Xi National Scientific Research Society.

Nels Sultan, P.E., Ph.D.

Role: This panel member was chosen to serve in a **dual role** for his hydrology and hydraulic engineering and geomorphology experience and expertise.
Affiliation: PND Engineers, Inc.

Nels Sultan, P.E., Ph.D., a coastal engineer at PND Engineers, Inc. in Seattle, Washington, has more than 20 years of experience specializing in the analysis and design of waterfront projects, including coastal geomorphology, coastal numerical models, and wave tank physical models. He earned his Ph.D. in ocean engineering from Texas A&M University in 1995. He is a registered professional civil engineer in Washington and Alaska and is a former officer in the Naval Reserve, Civil Engineering Construction Corps.

Dr. Sultan has worked on all aspects of design engineering for ports, harbors, shore protection, dredging, and other coastal and marine facilities projects. His extensive project experience includes preparing plans, specifications, and cost estimates through final design and construction (using a variety of materials including rock, geocontainers, stone masonry, and concrete), in addition to analyzing wave conditions, coastal processes, and sediment transport. Dr. Sultan's experience includes serving as the ocean engineer on the South Jetty Permeability project in Grays Harbor, Washington, where the jetty is subject to erosion of sediment at its landward end and has been completely severed from the mainland on occasion. Dr. Sultan analyzed aerial photographs, wind, wave, and tide conditions in order to determine whether the south jetty was permeable to sediment transport and contributing to erosion problems.

He served as project manager and coastal engineer for the Skagway Small Boat Harbor Dredging and Entrance Surge Control project in Alaska and led design and construction support services for a new 290 foot long, curved, partially penetrating vertical breakwater that provided surge control at the harbor entrance. Also for this project, Dr. Sultan prepared a wind and wave study for breakwater alternatives and provided computer modeling, using both desktop and CGWAVE modeling of wave transmission, wave diffraction, and reflected waves to evaluate waves at the adjacent ferry terminal floating dock and the shoreline north of the planned wave barrier. He also served as the ocean engineer for the Willapa Bay, WA SR-105 Stabilization Project Monitoring Program, which involved beach nourishment, an underwater dike, and a multi-purpose rock groin.

Dr. Sultan is a member of the Association of Coastal Engineers, American Society of Civil Engineers and the American Geophysical Union.

Daniel Maher, M.S.
Role: This panel member was chosen primarily for his experience and expertise in economics.
Affiliation: G.E.C., Inc.

Daniel Maher, M.S., is a senior economist and project manager at G.E.C., Inc. with 22 years of experience conducting large water resource/public works planning studies. He received his M.S. in agricultural economics from Louisiana State University in 1988. Mr. Maher has served as a project manager or economist on numerous regional economic impact, navigation, water supply, recreation, flood control, and ecosystem restoration projects. Mr. Maher has developed benefits and costs for National Economic Development (NED) analyses of large water resource planning efforts and navigation projects, which involved using methodologies estimating project benefits of coastal construction projects based on transportation savings. For example, Mr. Maher was the economist and project manager responsible for estimating NED benefits associated with increasing the current authorized depth of the federal central harbor and navigation channels to the Tenth Avenue Marine Terminal in San Diego, California. The primary benefits of deepening the harbor were the reduction in vessel operating costs by allowing deeper draft vessels to traverse the channel fully loaded, and the reduction or elimination of vessel tidal delays. Additionally, he was responsible for estimating the NED benefits and assessing the operational and environmental impacts resulting from the removal of several underwater natural obstructions in San Francisco Bay. These underwater pinnacles are considered a major hazard to navigation in the bay, especially regarding deep-draft oil tankers. The economic feasibility of removing these pinnacles was based on quantifiable transportation savings resulting from reduced bay transit distances of oil tankers and container vessels that frequent the ports on the bay.
Mr. Maher has also been responsible for cost effectiveness/incremental cost analysis (CE/ICA) for several USACE ecosystem restoration projects including Canonsburg Lake Ecosystem Restoration Project (Pittsburg District); Licking River Watershed and Dillon Lake Ecosystem Restoration Project (Huntington District); and Big Sunflower Ecosystem Restoration Feasibility Study (Vicksburg District). For each of these projects Mr. Maher worked with biologists and ecologists to define appropriate metrics for measuring environmental benefits and converting benefits to an average annual basis for each alternative considered. He also reviewed construction and operations and maintenance costs associated with each alternative, and conducted cost effective analysis and incremental cost analysis using IWR-PLAN. Mr. Maher has experience with numerous economic computer programs, including IMPLAN Economic Impact Software, IWR-Planning Suite, and IWR-MAIN Water Use Forecast System.

5. SUMMARY OF FINAL PANEL COMMENTS

The panel members agreed among one another on their "assessment of the adequacy and acceptability of the economic, engineering, and environmental methods, models, and analyses used" (USACE, 2010; p. D-4) in the Mouth of Columbia River IEPR. Table 3 lists the 25 Final Panel Comment statements by level of significance. The full text of the Final Panel Comments is presented in Appendix A. Of primary significance, and as discussed in several of the Final Panel Comments, the Panel has serious concern with the SRB model and the potentially over-emphasized role it played in the evaluation of alternatives, engineering design, and economic analyses. The following statements summarize the Panel's findings.

Plan Formulation Rationale: From a planning perspective, the Major Rehabilitation Evaluation Report is well done and in compliance with all of the typical formulation steps; however, it was never clearly explained that the scope of work was limited to the repair and rehabilitation within the present configuration, nor why it was limited in this manner. Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected. The Panel agreed that the SRB model is not a substitute for conventional engineering and economic analyses and should not be a stand-alone analysis for selecting a recommended plan.

Economics: The Panel identified three major issues in the economic analysis: (1) inconsistencies in the Major Rehabilitation Evaluation Report and economic spreadsheet models; (2) the assumption that navigation would not be impacted; and (3) the formulation of the base condition. Inconsistencies in the report and economic spreadsheet models pertaining to the calculation of NPVs and AACs prevented the Panel from validating the economic analysis. Based on the assumption that navigation will not be impacted, a least cost analysis was used in lieu of a transportation cost savings analysis to calculate NED benefits. Conflicting assumptions concerning the ability to maintain navigation invalidate the logic behind calculating NED benefits using a least cost analysis. As the project is currently formulated, the base condition maintenance strategy for the MCR jetties conforms most closely with the fix-as-fails strategy, while the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits. Each of these issues could impact the selection of the NED plan, which was selected as the recommended plan.

Engineering: There are serious technical difficulties with the Major Rehabilitation Evaluation Report and analyses. The report lacks a set of design criteria, including project life, standards of performance to be met, and environmental conditions with return period events. All are part of conventional coastal engineering design practice. The SRB model cannot be verified and does not include important processes. Major questions remain that have not been adequately investigated for this level of study, including subsurface geotechnical properties, feasibility of proposed barge offloading/material re-handling facilities, and the long term stability of the jetty foundations assuming continued erosion and loss of nearshore sediment. The report indicates that large volumes of sediment will move into the navigation channel after a breach event. However, the data and analysis do not support this conclusion. Additionally, is no clear discussion of the role of maintenance or emergency dredging, especially under extreme winter conditions. Detailed construction cost estimates also need to be provided in order for the cost analysis to be complete and verifiable. Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition.

Environmental: There is no discussion in the main report of sea level rise and potential wave height increases and its impact on this project over the 50+ year project timeline, given that the regional wave climate has been documented as more severe in the last 10 years. This has potential impacts to the project and in designing a project with lower long-term maintenance costs. Potential environmental impacts on sensitive species, upland habitats, and water quality as well as potential impacts to recreational use during project construction are not comprehensive nor adequately described in the mitigation plan. Finally, the alternatives are limited to armoring the existing configuration of the jetties and may not satisfy NEPA directive for alternative analysis.

Table 3. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel

Significance – High	
1	The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.
2	The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.
3	The underlying assumption that navigational impacts will not occur is not substantiated.
4	The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
5	The base condition, as formulated, does not represent the current O&M practice.
6	The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
7	The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.
8	The models and analyses of jetty failure do not include all significant processes.
Significance – Medium	
9	The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
10	A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
11	Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.
12	Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.
13	Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.
14	Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.
15	There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.

Table 3. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel, continued

Significance – Medium	
16	The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.
17	The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
18	The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.
19	Risk thresholds for selected alternatives are not clearly defined.
20	It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
21	The model output parameters and wave height components are not clearly explained and supported.
22	The culvert installation details, as well as potential impacts, need further clarification.
Significance – Low	
23	The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
24	Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.
25	Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.

APPENDIX A

Final Panel Comments

on the

Mouth of Columbia River IEPR

This page is intentionally left blank.

Comment 1:
The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.
Basis for Comment:
Economics is the key consideration in evaluating the NED plan, which was selected as the recommended plan. Several issues were identified in the review documents and the economic spreadsheet models that could significantly change the outcome of the economic analysis and the selection of the recommended plan. These issues primarily pertain to the calculation of net present values (NPVs) and Average Annual Costs (AACs), and the presentation of the economic analysis results. **Calculation of NPVs and AACs** • The AACs, based on the NPVs presented in Table 2-1 and Table 2-2, appear to be based on a Federal discount rate of 4.125%, not 4.375%, as stated in the report. • The calculation of the NPVs and AACs in the economic spreadsheet model for the North Jetty are based on a discount rate of 4.125%, not 4.375%, as stated in the report. • The period (actual calendar years) of the annual stream of costs used to calculate the NPVs for each alternative differ between alternatives in the economic spreadsheet models; also, the actual calendar years included in these periods were not stated in the report. • The unit costs for jetty repair and dredging, as presented in the SRB model, are increased over time such that after 50 years, costs will be 15% greater than at present. In accordance with ER 1105-2-100, p. 2-11 (USACE, 2000), when conducting economic analysis, prices should be held constant over the period of analysis. **Presentation of Results** • The NPVs and AACs in the spreadsheets for the North Jetty and South Jetty differ from the results presented in the report. • The term NED, the process of calculating NED benefits, and the method of selecting the NED plan are not explained in Section 2 or Appendix C of the report. • The SRB model uses Monte Carlo simulation to increase the confidence of life cycle estimates and allow for evaluation of variance by producing project cost output, including mean and standard deviation values (Appendix A2, p. A2-49). The risk and uncertainty associated with estimating the stream of annual costs and the resulting NPVs, AACs, and benefit-to-cost (B/C) ratios are not addressed in the economic analysis. • The costs of the NED plan of $250 million in the Executive Summary are presented on a fully funded basis, whereas the costs in the main report are presented as NPVs, resulting in confusion.
Significance – High:
The inability to validate the economic analysis and the assumptions used in the economic spreadsheet model could impact the selection of the NED, or recommended plan.

Recommendations for Resolution:
1. Calculate the NPVs and AACs using the FY10 Federal discount rate of 4.375% for all alternatives; basing the NPVs on the stream of project costs for the 50-year period of analysis. 2. In accordance with ER 1105-2-100, Chapter 2 (USACE, 2000), revise the formulas in the economic spreadsheet models to reflect the same period of analysis for all alternatives. 3. State the years (annual stream of costs) used in calculating the NPV for each alternative and ensure consistency in alternative evaluation. 4. In accordance with ER 1105-2-100, Chapter 2, p. 2-11 (USACE, 2000), revise the repair and dredging costs to reflect the general level of prices prevailing during or immediately preceding the period of planning for the entire period of analysis. 5. Revise Section 2 and Appendix C of the report to include a definition of the term NED, an explanation of the process of calculating NED benefits, and the method of selecting the NED the plan. 6. In accordance with EP 1130-2-500, Appendix B, p. B-9 (USACE, 1996), report the results of all alternatives in a table displaying the mean net benefits and standard errors of each; providing the 90% confidence interval for the mean net benefits (mean+ 1.64x standard error). 7. Present the costs of the NED plan in the Executive Summary and the main report in both a fully funded basis and in NPV.

Comment 2:
The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.
Basis for Comment:
The report describes large volumes of sediment that will move into the navigation channel after a breach event. However, the Coastal Modeling System (CMS) numerical model results (CHL, 2007; p. 15, Figure 3.2) indicate minimal sediment movement through a jetty breach, even with the model strongly distorted to encourage movement. Similarly, historic breach events at the MCR inlet and region do not support the sediment movement volumes and rates assumed, nor the assumed sudden jetty failure, and the consequent requirement for emergency repairs and dredging. The assumed jetty breach sediment movement is also inconsistent with recent experience with dredged material disposal at the North Jetty. Approximately 400,000 cubic yards were placed at the site each year during 1999-2008, on average, comparable to some jetty breach scenarios. However, the sediment placed at the North Jetty does not appear to have affected navigation. Similarly, the reported "rapid deterioration" of the North Jetty from 1999 to 2004, when 100,000 cubic yards of sediment leaked through the jetty leading to the repairs in 2005, is not consistent with the assumed scenario of a sudden breach event and large sediment movement. Figures A1-252 to A1-254 of jetty breach sediment movement appear to be artist renderings, not products of analysis. The figures are misleading if they are interpreted as model output. Table 3-10 in the main report is presented but not explained, so there is no clear basis for the "Range of Volume Left in Channel" resulting from a breach of the North Jetty. There is no discussion of any hydrodynamic analysis or evaluation of morphologic changes and corresponding sedimentation of the navigation channel. Significant inconsistencies are present in the sediment transport discussion. For example, the documents discuss sediment disposal practices at the shallow water site (SWS), immediately offshore from the tip of the North Jetty. The EA notes, "Active monitoring and evaluation determined that 80% to 95% of the dredged sand annually placed at the SWS moves northward onto Peacock Spit" (dispersed to the north). However, the main report describes how rip currents along the north side of the North Jetty transport sediment towards the tip and then south into the navigation channel. This implies an unrealistic discontinuity in the sediment budget and sediment paths immediately offshore of the jetty tip. The sediment budgets and analysis are not consistent in different parts of the review documents, and seem to vary depending on whether the analysis is centered on dredged material disposal (emphasizing sediment movement onto nearby shores) or jetty stability (emphasizing sediment movement towards the channel). The jetties are described as functioning like "wingdams" preventing sediment movement into the channel. However, it seems more the case that the North Jetty shields the sands of Benson Beach from the dominant southwesterly waves preventing/slowing longshore sediment transport to the north, rather than south into the channel. Also, the process of sediment

movement through a jetty breach is not at all like water through a dam break. The jetties are essentially a pyramid with only a small tip extending above water. What happens below water, with the sediments and foundations, is more central to the long term function and stability of the MCR jetties, navigation channel, and adjacent beaches.

A better analysis of sediment transport is needed because the repair alternatives at present are an ever expanding pile of rock on an ever shrinking foundation of sand. The geological history includes more than 225 million cubic yards of dredging since 1956 from the MCR navigation channel, with most disposed offshore (EPA, 2009). The Southwest Washington Coastal Erosion Study (Gelfenbaum, et al, 2006) concluded, "The carrying capacity of beach sands of Columbia River to the estuary has been reduced by approximately two-thirds over the last century." The missing sediment from the system and ongoing erosion of the shoals that help protect the jetties all point toward a need for a more rigorous investigation of sediment transport and alternatives that could reduce the loss of sediment and subsequent project O&M costs.

Significance – High:

The rehabilitation project will not be successful if ongoing sediment loss continues and the shoals and jetty foundation wash away.

Recommendations for Resolution*:*

1. Eliminate or justify the unrealistic assumption of sudden jetty failure and large volumes of sediment rapidly moving into the navigation channel. Instead, compare alternatives based on life-cycle costs including ordinary jetty repairs and maintenance dredging costs.
2. Provide a real analysis of sediment transport. Include review and reference to data and findings from maintenance dredging records and the studies of the MCR prepared for the multi-agency Southwest Washington Coastal Erosion Study.
3. Describe how implementation of this project will reduce ongoing erosion of the shoals.

Comment 3:

The underlying assumption that navigational impacts will not occur is not substantiated.

Basis for Comment:

The report clearly explains why navigation benefits were not analyzed. The method used to calculate NED benefits is based on the assumption that navigation will not be affected; the economic analysis is therefore based on a least cost analysis. This assumption, however, is not supported by the analysis presented in the report. A North Jetty breach in the winter is assumed to result in immediate mobilization of sediment that may impact navigation. If this assumption is true, it does not necessarily follow that emergency dredging will successfully occur to enable deep draft vessel access. As stated on p. 3-14 of the main report, under base conditions, during winter months, emergency jetty repairs and emergency dredging may not be possible, potentially resulting in impacts to navigation until the emergency activities are completed. The main report also states (p. 1-48) that operating a hopper dredge at the MCR during winter months has not yet been attempted.

The report does not address the impact of project construction and dredging activities on navigation. For example, the operation of a dredge in the MCR, especially under extreme winter conditions, could have an adverse impact on navigation in the MCR.

The Panel was unable to fully understand the potential impacts on navigation of shoaling resulting from a jetty breach. Since navigation benefits were not evaluated, impacts to the MCR or Lower Columbia River (LCR) channels as a result of shoaling after a jetty breach, in the absence of emergency dredging, is only presented in qualitative terms such as “navigation would be significantly impaired” (p. A2-34). The extent of the impacts are not described (i.e., bar closure, vessels delayed due to having to use tides to access the channel, reduced under-keel clearances, vessel lightloading, etc.). Due to the dismissal of potential navigation impacts, no mitigation is defined.

Significance – High:

Conflicting assumptions concerning impacts to navigation invalidate the logic behind calculating NED benefits using a least cost analysis and impacts the selection of the NED, or recommended, plan.

Recommendations for Resolution:

1. Conduct a transportation cost savings analysis to calculate NED benefits.
2. Include a description of the expected channel depths available after a breach event, and in the absence of emergency dredging, include a description of the portion of the fleet using the channel that will be impacted by the resulting shoaling.

Comment 4:
The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
Basis for Comment:
The SRB model results cannot be verified, as it is a custom-made engineering and economics model applicable only to this project and there is no means for the Panel to examine the inner workings of the SRB model and its internal calculations to assess its "adequacy and acceptability". It is not possible to verify model results, or to repeat the application of the SRB model because there is no User's Manual or detailed description of model inputs and how the model was applied for the Mouth of Columbia River project. Furthermore, the model has not been peer reviewed or tested. Without documentation of successful application, the Panel cannot validate the model or have confidence in the results. The SRB model internal calculations and logic are not a commonly applied method for calculating rubble mound structure reliability and damage. The model analyzes more than 600 variables, stacking process upon process, each with wide error bars, resulting in the accumulation of errors. Significant processes do not appear to be included in the model, such as armor rock breakage and deterioration and deep seated slip-circle failures. Figure A2-18a shows model output for jetty cross-section progressive damage. This figure provides one of the few insights into the inner workings of the SRB model. The figure indicates the physics and process of jetty decay are not modeled correctly because the output is not consistent with cross-sections of observed damage. The engineering evaluation does not include much about the physical modeling (i.e., wave tank results). It seems the wave tank model was used to develop the input and equations within the numerical SRB model. It is more conventional to proceed in the opposite sequence, to use a wave tank model to verify a final design concept and verify numerical model predictions. The wave tank model effort was substantial and likely yielded good insights. However, it does not appear that results were used to their fullest potential because the model output and findings were only applied through the SRB model process. The wave tank model results could have been used as part of an independent evaluation, providing an additional line of evidence along with other investigations, data, and findings. The SRB analysis should only be used as one of many tools in the alternatives evaluation rather than a substitute for the preliminary engineering design. Additional engineering analysis and design documentation needs to be provided as part of the preliminary engineering design report. Documentation through the preliminary engineering design process will lead to improved confidence and reliability of SRB analysis.
Significance – High:
The SRB model functions as a "black box" and does not allow an alternatives analysis that is clearly based on sound technical evidence of engineering design performance.

Recommendations for Resolution:

1. Move the SRB model to an appendix, as supplemental information, and assign it a weight of 10% in the evaluation of alternatives. No further work on the SRB model is recommended as part this project.
2. Include a detailed description of the SRB model application allowing verification of model calculations and how the model was applied to the Mouth of Columbia River project.
3. Demonstrate that the model has been peer reviewed and tested.
4. Move the calculations and elements of the study currently within the SRB model (such as rubble-mound damage, slope stability failure, design wave heights and water levels, economic calculations, and much more) out of the SRB model and provide as separate calculations that can be checked and verified.
5. Provide documentation of preliminary engineering analysis and design which would constitute the basis for the SRB analysis. The preliminary engineering analysis should be provided in the report, with details in appendices. Elements that appear missing or inadequate at this level of design include the following:
   - Design criteria and basis of design
   - Structure condition assessment and existing condition survey
   - Subsurface geotechnical investigation
   - Development of jetty repair/rehabilitation alternatives
   - Hydrodynamic analysis (waves, currents, sediment transport) specifically related to the alternatives
   - Determination of stone sizing for alternatives
   - Alternative evaluation
     - Development of evaluation criteria
     - SRB analysis
   - Detailed volume and cost estimate for the alternatives.

Comment 5:
The base condition, as formulated, does not represent the current O&M practice.
Basis for Comment:
The present and future base condition maintenance strategy for the MCR jetties, as currently described in the report, conforms most closely with the fix-as-fails strategy. Under this scenario, jetties will be allowed to deteriorate to the point that just-in-time repairs may not prevent a breach in the jetty, which would result in expensive, winter dredging activities. As the project is currently formulated, the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Historical maintenance efforts for MCR jetties are best described by an interim repair strategy. As a result of monitoring and advance repair activities, historically there have been no jetty breaches that have impacted navigation, nor has winter dredging been needed to maintain navigation. EP 1130-2-500, Appendix C, p. C-1 (USACE, 2006) states that for Major Rehabilitation Projects, under the base condition, "maintenance is increased as needed (but within limits) and components or sub-features are repaired on an emergency basis. This essentially represents the current O&M practice." Based on the report, this condition would resemble an interim repair strategy, rather than the fix-as-fails strategy currently described as the base condition.
Significance – High:
Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits for all action alternatives thus impacting the benefit to cost ratios.
Recommendations for Resolution:
1. Refine the base condition to more closely resemble the current O&M practice, in accordance with EP 1130-2-500, Appendix C (USACE, 1996).

Comment 6:
The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
Basis for Comment:
Potential breaching of the foreshore dune at the South Jetty root, to form a new connection to Trestle Bay, is discussed briefly in a few places, including a proposed cobble berm to mitigate this risk in the main report (Section 3.5.3.3, pp. 3-40 - 3-41, p. 7-1 and elsewhere). Additional analysis is appropriate given the consequences of breaching at this location. It is not clear what analysis has been conducted to evaluate the performance of the proposed dune augmentation. It is not known if the volume of material per linear foot is sufficient to provide the required width of cobble beach for stable conditions upon adjustment after initial placement. Maintenance requirements are not known for this design. Studies by DOGAMI (Allen, 2005) have been conducted on dynamic revetments for shoreline stabilization on the Oregon Coast but do not appear to have been applied. The breaching potential will likely increase with increasing shoreline erosion and loss of sediment from the system. However, potential beneficial use of dredged sediment is not analyzed as part of a design solution for a breach. Long-term erosion trends are assumed and are not adequately addressed in the report. The information provided is inconsistent in this area, with some sections saying the South Jetty dune erosion/augmentation issue will be addressed as part of a separate project, whereas other report sections include South Jetty dune augmentation as part of this project. Foreshore dune breaching has occurred at other coastal inlet navigation jetty structures along the Pacific Coast such as the South Jetty at Grays Harbor, Washington. Beach renourishment with dredged material and jetty structure modification improvements to prevent dune breaching were made with varying levels of success. It is not clear whether these similar project conditions and performance have been evaluated as part of the development and analysis of alternatives at the Columbia River South Jetty location.
Significance – High:
Breaching the dune at the South Jetty root appears to be a substantial risk, with more immediate consequences than breaching of a jetty because of the potential for forming a new tidal inlet with relatively rapid widening and deepening.
Recommendations for Resolution:
1. Either include the South Jetty dune augmentation/stabilization as part of the alternatives, and include costs and preliminary engineering, or state that it is not an element of the proposed work and is part of a separate project. Either way, potential breaching scenarios should be evaluated/modeled and included in the sediment transport and hydraulic analysis. This major investigation is the logical place to add studies of the MCR system (including jetties, navigation channel, estuary, and beaches). 2. Account for long-term shoreline erosion/recession trends in the design.

3. Review other jetty rehabilitation project solutions and performance at coastal inlet navigation facilities such as those conducted at the Grays Harbor South Jetty (Wamsley, 2006).

Comment 7:

The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.

Basis for Comment:

The document “design_criteria_info.doc” is vague. It discusses “50 year alternatives,” but the term is not defined. It could mean many things, including the following:

1. The project life is 50 years, with complete replacement assumed after 50 years.
2. Design jetty repairs that have the least life-cycle costs over a 50 year period.
3. The economic planning horizon, benefits and costs, are calculated for 50 years.
4. Design to withstand a series of storms over a 50 year period.
5. Design to withstand a single 50 year return period storm event.

Section 3.5.2.1 (Cross Section Intent and Design Philosophy) states, “The repair template must … allow the maximum repair within funding limitations.” This indicates the main design criterion is to provide the most repair possible within a budget limit, rather than design to withstand environmental loads and forces. The “funding limitations” are not stated, yet appear to be behind many of the design and planning decisions. Using funding limitations as a design criterion is not the same as an engineered design that meets environmental loading criteria. The funding limits design criteria are not consistent with the environmental loading design criteria in “design_criteria_info.doc.”

Note that a 50 year project life does not necessarily mean one should apply a 50 year return period event for the design environmental criteria. For example, a petroleum development platform may have only a 35 year project life, but the project may be designed to withstand a 100 year return period storm event or longer. The consequences of jetty failure should be considered in establishing the design criteria. ISO standards are sometimes applied in practice, but do not seem to be included in this work. Additionally, USACE (1995; paragraph 2-4) states rubblemound structures should be designed to successfully withstand the conditions that have a 50% probability of being exceeded during the project’s economic service life. The economic service life needs to first be established as a criterion and then the design storm formulated to meet the acceptable risk level for that service life.

A span of 50 years may be appropriate for an economic planning horizon; however, a 50 year project life or a 50 year return period storm event does not seem reasonable for engineering design considering the importance of navigation through the MCR. The structures should be designed to last indefinitely, as permanent structures, with regular maintenance requirements estimated and included in an economic analysis.

The 50 year criterion may not be consistent with parts of the report that mention a longer period of time. The SRB model discussion in Appendix A2, p. 78 states, “The period of analysis for future condition simulations was 64 years (2006 to 2070) for the North Jetty and Jetty A and 63 years (2007 to 2070) for South Jetty.”

Appendix A2 (p. A2-8) states, "The MCR jetties were constructed to achieve an expected service life of 50-100 years," and concludes that 0.7% per year is the expected maintenance cost based on the 50-100 years service life. The 50-100 years service life, and associated 0.7% figure is used to inform the analysis and to demonstrate a lack of maintenance. However, the original 50-100 years service life, and 0.7% annual expected maintenance cost are arbitrary assumptions. The historic assumed service life and maintenance needs are not supported by the information presented, and largely irrelevant to today's design and maintenance criteria.

The design criteria, if any, from 100 years ago when the jetties were built are not presented and previous maintenance are considered an operational cost. Analysis of past maintenance also may distract from the main problem afflicting the jetties: poor design 100 years ago, not deferred maintenance.

The original builders, working before the development of modern coastal engineering methods, underdesigned the jetties with only 7 ton armor rock, at their angle of repose of 1.25h:1v, or steeper. In addition, they constructed the immense structures on ever shifting sand shoals, locating them where the shoal happened to be at the time of construction, without adequate design features to account for shifting channels and currents.

The starting assumptions and criteria and alternatives are so narrowly constrained that there is questionable value in much of the analysis. The Major Rehabilitation Evaluation study is set up so that the end result is always the same; more rock within the existing jetty footprint. Conventional coastal engineering practice for a project of this scope would include the following:

1. Analysis to determine how much jetty is really needed today to maintain the navigation channel at reasonable cost. The Panel questions whether all 9+ miles of jetty are optimal. There has been no upward trend in maintenance dredging volumes since 1956, despite continued jetty tip recession, which indicates shorter jetty lengths would be equally functional at less cost.

2. Evaluation of alternatives that are not constrained to the original footprint, not built to the maximum crest elevation and authorized length feasible, not constrained only to rock, and discussed or considered beneficial use of dredged material as a design element.

3. Evaluation of durability issues and lessons learned from related projects. For example, the Dover Pier in England has lasted well over 100 years. Similarly, the Humboldt Bay jetties and Crescent City jetties in Northern California have effectively stopped jetty head recession using 40 ton dolos concrete armor units, and the Japanese are building breakwaters with 90 ton dolos concrete armor units.

Significance – High:

The lack of criteria prevents NED analysis and evaluation of whether the structure design meets standards.

Recommendations for Resolution:
1. Establish conventional project criteria including project life, standards of performance and function to be met, and environmental loads and return period events, which are part of conventional coastal engineering design practice. Document in a Preliminary Design Report. 2. Establish Design Environmental Conditions that have a specific return period. 3. If unable to meet the design criteria due to budget limits, state the budget limits as a criterion, and estimate what the equivalent design life or expected performance will be for the compromised design. 4. Expand the starting assumption to allow: a. Beneficial use of dredged material as a component of jetty rehab. b. A design outside the existing jetty footprint c. A design that may allow jetty head recession up to a point when maintenance dredging needs increase. d. A design that can include a partially submerged jetty cross-section. 5. Use a longer return period than 50 years for the design environmental criteria and consider ISO standards. 6. Consult with Dover Pier representatives and other jetty builders to discuss durability issues and lessons learned from their project in order to benefit the MCR project.

Literature Cited:

USACE. (2005). Design of Coastal Revetments, Seawalls, and Bulkheads. Department of the Army, U.S. Army Corps of Engineers. Manual EM 1110-2-1614. June.

Comment 8:
The models and analyses of jetty failure do not include all significant processes.
Basis for Comment:
The SRB and STWAVE models cover many significant processes and variables that affect long-term jetty stability; however, some variables and processes are missing that should be presented in the SRB model and the Major Rehabilitation Evaluation Report: • Armor rock breakage, rounding and wear, which can significantly affect jetty performance, do not appear to be included in the analysis. • Deep seated slip surface failures through the jetty section, a global failure similar to a landslide, also do not appear to be analyzed and may be a significant risk. • Wave height in combination with currents can cause significantly higher sediment transport rates than waves only or currents only. It is not clear if sediment transport analysis, considering both waves and currents acting together, has been done. • Long-term changes in outlet channel morphology do not appear to be analyzed. The process of jetty decay through tidal channel scour appears different at Jetty A than at the North or South Jetties. Tidal channel scour at the tip of Jetty A will not be mitigated by adding spur groins, therefore a different system will need to be designed at Jetty A and accounted for in the jetty performance analysis. The STWAVE model is not sufficient for modeling detailed wave transformations. Important processes such as wave structure interactions, refraction, and diffraction are incorporated in STWAVE using approximate methods. Other models like BOUSS-2D and CGWAVE are readily available and model the physics of these important processes more directly. STWAVE is appropriately applied as a regional wind-wave generation model for regions without a complex bathymetry. However, the Mouth of the Columbia River morphology near the jetties and navigation channel is complex. A phase-resolving wave transformation model such as BOUSS-2D or CGWAVE should be applied at this level of design in addition to STWAVE.
Significance – High:
The analysis of potential jetty failures, waves, currents, and sediment transport is incomplete for this level of design, and may result in significant errors in the evaluation of alternatives. Errors could include underestimating the design wave height, leading to undersized armor rock, excessive maintenance requirements and structure failure.
Recommendations for Resolution:
1. Estimate future repair needs and armor rock characteristics based on past performance of rock at the jetties. This requires a more detailed survey of existing condition, including quantifying existing armor rock size, gradation, and shape. 2. Analyze foundation stability based on measured geotechnical properties. A subsurface geotechnical investigation, including borings and soil testing, is recommended. 3. Provide a design concept for scour protection at Jetty A and check its stability against design environmental criteria, including specific current speed and wave height.

4. Apply models and use analysis methods to investigate sediment transport patterns and jetty foundation erosion under a combination of both waves and currents.
5. Supplement the STWAVE model with a wave transformation model such as BOUSS2D or CGWAVE to help determine design wave heights near the jetties.

Comment 9:
The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
Basis for Comment:
The design alternatives presented in the document are limited to the repair and rehabilitation of the jetties within the present configuration. The Panel is concerned about the adequacy of the alternatives analysis and the limited range of alternatives considered. NEPA Section 1502.14 requires a rigorous examination of all reasonable alternatives to any proposal and justification of eliminated design alternatives. The Panel finds that there is little examination of alternative approaches to the principal function of the MCR jetties, which is to secure a consistent navigation channel across the bar at the MCR. As such, the narrow scope of alternatives presented weakens this project. Insufficient information is provided to justify limiting the improvements to the existing footprint. For example, the report does not provide the technical basis for maintaining the 1895 jetty design, length, and orientation to the exclusion of considering other configurations. Considering reasonable alternatives, under NEPA guidance, would allow USACE to use hydrodynamic modeling tools to evaluate alternatives such as the use of weir jetties (Seaburgh, 2002) and other sediment management methods that facilitate bypassing sediment at coastal inlets, as well as low wave and high wave depositional basins in a manner which may reduce long term operation and maintenance costs. The impact of not considering additional alternatives leaves the overall justification of the project less defensible and may lead to questions of the overall merit of the rehabilitation project
Significance – Medium:
Consideration of alternatives beyond rehabilitating the original jetty structures within their existing footprint would comply with NEPA directives, and provide critical information that may reduce long-term costs and improve jetty life and efficacy.
Recommendations for Resolution:
1. Assess, and validate or reject, the technical basis for the initial jetty design, length, and orientation using appropriate physical coastal process models. 2. Assess structural efficacy and cost of alternatives which are not constrained by the existing footprint. 3. Develop modeling efforts for hydrodynamic models and/or sediment transport models that would provide insights into the following areas: a. Thorough analysis of the existing jetty structures focusing on why some areas have survived without repair and others have needed repeated repairs b. Examination of why Jetty A had such a large O&M cost relative to predictions. c. Addition of subsurface berms potentially created through the beneficial use of project dredged material that may reduce wave impact and subsequently reduce wave overtopping and toe scour.

Literature Cited:

Seaburgh, W. C. (2002). Weir Jetties at Coastal Inlets: Part 1, Functional Design Considerations. U.S. Army Corps of Engineers, ERDC/CHL CHETN-IV-53. December.

Comment 10:
A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
Basis for Comment:
The extent of structure failure or partial failure is well documented and the repairs made to the structure are well documented, as shown in Figures 1-12, 1-15, and 1-16. These figures, however, do not distinguish between areas repaired and areas that are substandard but have not failed and so were not actually repaired. Failure analyses for the groin tips and the runnel formation weakening Jetty A (p. 3-5) are presented, but the report does not include a general failure analysis. A failure analysis would be helpful in determining why one section of jetty failed/degraded whereas another remained intact. This information is needed to derive alternatives that resist both degradation and failure, and result in an informed design of jetty repairs. Maintenance histories (Figures 1-21 through 1-23) show that actual O&M costs have trended significantly above and below the expected O&M costs, based on annual expenditures equivalent to 0.7% of the initial construction costs. Specific causes of actual O&M costs being higher or lower than the assumed 0.7% annual average cost have not been analyzed but can be presumed to be directly related to full or partial failure of portions of the structures. Knowledge of the specific causes of failure combined with the cost of constructing a jetty resistant to these causes taken in consideration of maintaining a jetty less resistant to these causes may be useful in determining or presenting the most cost effective alternative design. A specific presentation of individual jetty failure events would serve to bolster the alternative selection process and the projections of future maintenance costs.
Significance – Medium:
Uncertainty regarding the specific causes of failure and their relationship to trends of past O&M costs creates a functional uncertainty in the corrective measures in the alternatives for repair and rehabilitation.
Recommendations for Resolution:
1. Include an analysis of the causes of failure for each repair event (e.g., Figure 1-15) even if only a statement of "storm intensity" in order to provide assurance that the repairs address the actual causes of previous jetty failures. 2. Relate construction costs of more resistant designs to repair costs of less resistant designs for each causal condition of failure and the associated selected alternative.

Comment 11:

Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.

Basis for Comment:

The issue of climate change, sea level rise, and increased wave action is important to consider in the evaluation of long-term projects (USACE, 2009). There is no discussion in the main report of sea level rise and its impact on this project over the 50+ year project timeline. There is a limited discussion of climate change in Appendix D (p. 5), where the conclusion is that since the projected historical trend of sea level at the project site is estimated to be -0.05 feet in 50 years, sea level rise is not projected to be a significant climate change factor at the project site. Appendix D states the "comprehensive analysis of historical storm events is expected to adequately capture the present deep water contribution of potential wave height variation for this project site. The above approach forms the basis for estimating the potential changes in wave climate that could affect the MCR jetty system." However, this discussion on wave height trends is not compelling. The main report states (p. 1-6), "As the tidal shoals continue to recede (erode), the MCR jetties will be exposed to larger waves and more vigorous currents. To make matters worse, the regional wave climate along the Northwest Pacific Coast has become more severe in the last 10 years. The offshore 100-year wave height has been revised from 41 to 55 feet." (see also Appendix D). The main report states (p. 3-42), "The limit of cross-section resiliency is reached for jetties when the core stone becomes exposed to wave attack." Therefore, this issue may affect jetty erosion and a larger range of wave heights should be included in both the SRB and STWAVE model scenarios.

Wave overtopping is central to the environment deteriorating the existing jetties. As the planning horizon of this project is 50+ years, it seems that a discussion would be useful of sea level rise and modeling potential wave heights and the wave overtopping impacts on the jetties given different rates of recession under a wider range of wave heights. Jetty height and crest elevation are variables that should be modeled given the potential larger wave heights possible under sea level rise. Although the selection of the recommended plan may not change, long-term maintenance costs may be affected, therefore consideration is warranted.

Appendix B states that transient internal hydraulic effects of wave impact may be the most important parameter in the stability of the jetties. However, it is the least certain of all of the parameters. Internal hydraulic pressures in jetties have not been measured. Given this, it seems especially important to consider more extreme wave heights beyond the wave height analyzed, with respect to sea level rise and potential increasing wave height.

Significance – Medium:

The discussion of potential impacts of sea level rise and increased wave action on jetty structures is critical to understanding the potential impacts to the project and in designing a project with lower long-term maintenance costs.

Recommendations for Resolution:
1. Add a separate section to the Major Rehabilitation Evaluation Report that examines climate change, sea level rise, potential wave height changes, and resulting wave overtopping impacts on the jetties given different rates of recession under different model scenarios.

Literature Cited:

USACE (2009). Water Resource Policies and Authorities Incorporating Sea-Level Change Considerations in Civil Works Programs. Department of the Army, U.S. Army Corps of Engineers, Washington, D.C. Engineer Pamphlet EC 1165-2-211. 1 July.

Comment 12:

Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.

Basis for Comment:

A detailed construction cost estimate summary should be provided for the recommended plan, otherwise the basis for the total cost values provided in Section 6.5.9 cannot be reviewed and assessed to determine if they are realistic and complete. The cost estimate information provided in the main report (Section 6.0) and in Appendix E is not sufficient to support the recommended plan:

- Table 6-3 provides a detailed summary of stone volumes for each jetty by construction year, but there is no correlation with construction costs or to the cost estimates provided in Section 6.5.9 or Appendix E.
- Specific cost estimating details are provided in Sections 6.5.7 and 6.5.8, but the assumptions and criteria defining the basis for the cost estimates do not include any summary unit costs for the individual work items.
- Unit costs are provided in Tables A2-9 to A2-11 but pertain to the SRB modeling effort. There is no discussion regarding how they relate to the final project costs presented in Section 6.5.9.
- Appendix E includes budget summary costs for construction, planning/engineering, construction management, and land acquisition. Detailed cost estimates for the Civil Works construction budget numbers are not provided and the basis for the costs cannot be reviewed or verified.
- Costs for the barge offloading and material re-handling area facility installation and maintenance are not described, yet they could be a large direct and indirect cost to the project based on wave exposure (for type and size of barge offload facility structures). The structural requirements (and corresponding construction costs) for an exposed vessel berth will be many orders of magnitude larger than the same berth in protected waters. Stone delivery cost represents a very large percentage of the total cost. Ensuring a cost feasible method of delivery to the jetty structures is critical for development of an accurate cost estimate.

Significance – Medium:

Detailed construction cost estimates need to be provided in order for the cost analysis to be complete and verifiable.

Recommendations for Resolution:

1. Provide a detailed cost breakdown by work item for the Civil Works project item, Breakwater & Seawalls. Provide detailed cost estimates for each major element of work (e.g., mobilization, stone supply and install, site preparation, material re-handling facility installation, maintenance of re-handling facilities, etc.). Give details regarding work item quantity, unit costs, contingency, and escalation.

2. Provide a detailed cost summary within Appendix E, and an additional detailed description of the basis for the costs estimates in Section 6.
3. Conduct an additional investigation of re-handling facility requirements to adequately determine the costs for facility installation and maintenance.

Comment 13:
Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.
Basis for Comment:
Appendix D and main report (pp. 5-17--5-20) list potential in-water, wetland, and upland impacts. These impacts should be addressed in the mitigation plan. The mitigation plans currently address these three general categories, but do not provide mitigation for potential impacts to specific species, upland habitats and water quality. The mitigation plans are incomplete because the final wetland delineation for the project has not been conducted, and the impact to wetlands and upland habitat is uncertain and therefore not quantified. A vegetation restoration plan is needed to address potential impacts to upland habitats, especially the rare and vulnerable species discussed below. At a minimum, the mitigation plan should state that these plans will be prepared prior to construction activities. Although the extent of the upland impact on this habitat is uncertain, a replanting contingency plan and a clear plan for avoidance are important to include in the mitigation plan. Similarly, potential water quality impacts from spills should be addressed in the mitigation plan with a statement about the spill prevention plan, as discussed below. Section 5.1 (Environmental Effects) of the main report provides details on biological resources, but is missing a vegetation section. Appendix D contains two reports including the Wetland and Waters of the U.S. Delineation Report and The Plant Communities Investigation Report, April 2007, which provides details on the vegetation communities; however, this information is not presented in the main report and therefore the main report lacks a definition of the plant species of concern within the project area. The revised EA states (p. 6) that at least three of these vegetative communities (shorepine-slough sedge, shorepine-Douglas fir, and coast willow-slough sedge) "have been ranked globally and by the State for their rarity and vulnerability to extinction and should be protected from impacts." This information on sensitive species should be integrated into Section 5.1. Furthermore, potential land construction activities as shown on Figure 5-1 of the main report may affect plant communities, including sensitive habitats, warranting a discussion of existing vegetation in the project area. Vegetation impacts that may result from construction are not detailed in the document, and just briefly mentioned in regards to the South Jetty. Mitigation plans should include specific protective measures to avoid potential impacts to these rare and vulnerable species. In general, the main report discusses Endangered Species Act (ESA) species, but does not provide detailed data on specific animal or plant populations. In 2005, critical habitat was designated for all Columbia River steelhead and Columbia River salmon evolutionarily significant units (ESU), with the exception of lower Columbia River coho salmon ESU. Although a wide range of potential impacts are discussed (p. 5-16), ranging from loss of habitat to an increase in perching and in-water habitat for predators that prey on listed species, the mitigation section of the Major Rehabilitation Evaluation Report does not address these impacts. The main report concludes (pp. 5-19 – 5-20) that there will be overall benefits to these species from this project. Additional details would be helpful to ensure that these species suffer no impacts. The Panel realizes that as a specific mitigation plan is developed, this may

likely be incorporated.

Water quality may also be affected over the project duration due to the large volume of container ships, construction dredges, barges, and cruise ships operating in the area, sometimes in adverse extreme weather conditions. For example, there may be a loss of hydraulic fluid or oil spills (p. 3-70). In the discussion of the mitigation plan in Section 5.4 (p. 5-17), the increased risk of pollutant release and spill potential is raised as a potential impact on ecosystem function. A sentence earlier in the document (p. 5-2) states that the Contractor "will provide a spill prevention plan to include measures to minimize the potential for spills and to respond quickly should spills occur." This sentence belongs in Section 5.4 of the main report as well.

Any history of spills in the Mouth of Columbia River area should also be reported in the document. Providing these details will enable a more thorough analysis of environmental impacts and enable additional protective actions to be implemented.

Significance – Medium:

Additional biological resources data and potential impacts to sensitive species, upland communities and water quality is needed to adequately protect the environment and define the mitigation needed to reduce these impacts to less than significant.

Recommendations for Resolution:

1. Incorporate additional information into Section 5 of the report:
   a. A vegetation section defining the sensitive species within project area.
   b. A statement to ensure that stockpiling activities shown in Figures 5.1 – 5.3 of the main report minimize the land impacts to sensitive habitats and wetlands. State whether a survey will be conducted prior to construction activities with sensitive habitats flagged to ensure avoidance.
   c. Provide detailed data on specific animal or plant populations that are listed species
   d. Specific text in the mitigation section for potential impacts to steelhead and salmon.
2. Add the wording from p. 5-2 into Section 5.4 of the mitigation plan regarding the contractor's requirement to prepare a spill prevention plan to address potential water quality impacts. Document any known history of spills in the area.

Comment 14:
Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.
Basis for Comment:
The Major Rehabilitation Evaluation Report does not provide detail on the impact of the project construction activities on recreational use, an issue that came up in public comment letters (main report, Section 5.4). The last sentence in Section 5.3 states that there will be no significant impacts on recreation. Appendix C states that there is a growing cruise ship industry and it is unclear how construction activities will affect passenger cruise ship access. On p. C-3 it states that 5/7 day cruise ship tours carry 15,000 passengers annually, and thousands of tour boat passengers take day trips and dinner cruises. These activities generate about $15 to $20 million in revenue annually for local economies. Public access during construction may be an issue. In addition, other recreational uses of the area may be reduced, such as kayaking and hiking. These impacts should be defined, rather than concluding that no recreational or economic impacts to tourism are expected. Omitting this issue may lead to unforeseen consequences for the cruise ship and tourism industries.
Significance – Medium:
Recreational impacts are not adequately presented in the report and subsequently, no mitigation is identified for this potential impact.
Recommendations for Resolution:
1. Add a discussion of the cruise ship industry and other recreational uses at the project site. 2. Examine potential impacts on cruise ships and other recreational activities that may result from the dredging operations and jetty repair operations. 3. Provide potential mitigation options to reduce recreational impacts to less than significant levels. 4. Make a distinction between recreational impacts during construction and after construction.

Comment 15:
There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.
Basis for Comment:
Contract-provided barge offloading facilities for the South and North Jetties are described in Sections 6.3.3 and 6.3.4 and shown in Figures 5-1 and 5-3 of the main report. Based on the information presented, it is not clear that these sites have been adequately investigated and are suited for their intended use. The barge offloading and material re-handling facilities at these outer exposed locations should be further investigated to ensure they are economically and operationally feasible. The proposed facilities are referred to as "temporary," but this is questionable if they will be in place for 20 years. The life-cycle costs of the docks and other structures are not trivial and do not seem adequately analyzed. The largest cost and a substantial risk for the recommended plan involves the purchase, transportation, delivery, and offloading of the stone in a very difficult environment over a relatively long time. The USACE-provided sites also need to be operationally feasible in order to use a permitted method of delivering material to the site. Providing contractors with better information on the limitations and usability of these sites at the time of bidding could result in substantial cost savings. There is no discussion in the report of any engineering work performed to evaluate the feasibility of installing structures at these exposed locations, nor any mention of operational feasibility for the size of vessels and wave climate for the periods of construction. These locations are subject to wave heights of more than 15 feet, which will impose very large wave impact loads on fixed structures (dolphins and sheet pile walls), resulting in high risk and cost facilities. USACE intends to permit these sites and provide them to the contractor as the primary point of access. This establishes a certain level of perceived usability to bidders. If they are later determined not to be feasible (i.e., during contract bidding or during construction), it would result in substantial cost and schedule changes. Use of the re-handling facilities will be limited to a "summer" work period (April to October). There is no analysis of sedimentation rate in the report to verify whether the floatation channels will remain open for the summer construction work period. Maintenance dredging estimates for barge offloading facilities are provided in Table 6-1, but it is not clear for what time period (annually or total over the entire duration of the project). Jetty A is listed at 80,000 cubic yards for maintenance dredging. Other options, such as dredging within the Ilwaco channel to the trunk end of Jetty A and developing an offloading facility adjacent to the staging area could be considered.
Significance – Medium:
Insufficient information on the limitations and usability of the offloading and re-handling sites could affect construction cost estimates and project schedule due to operational and physical environment constraints.

Recommendations for Resolution:
1. Conduct a feasibility level engineering analysis and design for the contract-provided offloading and rehandling sites to ensure that selected sites and facilities are feasible and provide reliable estimates of construction cost. The feasibility evaluation should at a minimum include the following: a. Evaluate feasibility of constructing pile supported structures within an extreme hydrodynamic environment. This includes wave/current loads on moored vessels during the construction period and wave/current loads berth structures during extreme winter conditions. b. Evaluate downtime of barges at the proposed sites relative to the wave and current climate during the proposed construction work period. c. Refine the type of structure that is feasible for these locations for inclusion into project permits and cost estimates. 2. Evaluate the need for alternative barge offloading and material re-handling site locations based on the results of the feasibility analysis. 3. Evaluate design concepts for permanent barge/dock facilities, possibly incorporated into the inside face of the jetties near their root. 4. Develop environmental data specific to the proposed offloading site locations for bidders/contractors to use in developing their estimates of downtime and infrastructure requirements at USACE provided rehandling sites. Extreme event offshore wave data and jetty structure design criteria will not be sufficient for contractors to use in evaluating short-term operational and design requirements.

Comment 16:
The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.
Basis for Comment:
Dredging is a substantial component of this project and has been historically, yet there is no clear discussion of the role of dredging in the Major Rehabilitation Evaluation Report. Typical annual dredging rates are not presented in the document itself, although Appendix A1 (p. A1-3) states, "Each year, the Portland District dredges 3 to 5 million cubic yards (MCY) of sand at MCR to maintain the 5-mile long deep draft navigation channel." It is unclear if the Portland District dredging is conducted exclusively at MOCR. Analysis of the project area maintenance dredging requirements – past, present, and future – have not been presented. Controlling dredging costs is critical to this project. The EPA publishes a report annually analyzing dredged sediment disposal in the nation. About 4 million cubic yards is dredged at the MCR every year at an annual cost of about $10 million. The fact that maintenance dredging volumes in the project area have not increased (no clear trend) since 1956, despite ongoing jetty tip recession, raises the question of how much jetty is now needed to maintain the MCR navigation channel. However, the main report does not discuss details of the maintenance dredging. Appendix B states the geological history includes 225 million cubic yards of dredging from the MCR navigation channel since 1956. The volumes, history, and fate of these dredged sediment volumes should be described in the main report and are missing from the analysis. The fact that most of this sediment was dumped far offshore and lost to the nearshore may have something to do with the erosion experienced in the area. This large quantity of dredged material warrants discussion and additional consideration of strategies to reduce this volume. The discussion of emergency dredging is also lacking in the main report. The historical downtime for dredging at the dock and jetty repair work during the time period of October to March (peak period for large waves) is not provided. Page 3-70 states, "Given the winter wave conditions that the dredges would be performing in, it is highly likely that damage would occur to the drag arm of the dredge while working." Page A2-65 states that within the SRB model "there is a 0.3 probability that one dredge will lose a drag-arm while performing dredging during winter or a 0.7 probability that one dredge would realize equipment damage," thereby increasing dredging costs. Several places reference the difficulty of dredging in the winter. Conditions may preclude effective dredge use, or the dredge may break and become inoperable, suggesting dredging may be postponed until summer. In terms of dredge operation, p. 1-48 gives the operational limitations of hopper dredges, and admits that operating a hopper dredge at the MRC during winter months has not yet been attempted. Therefore, the inadequate demonstration of equipment effectiveness, lack of documentation of the basis of dredge damage probabilities, and lack of historic utilization increases the risk associated with estimating costs associated with emergency dredging. The document states on p.1-50 that the rate of shoaling within the MCR channel would not be high enough to require emergency dredging; therefore, the increased shoaling volume could be dredged the following summer and would not be considered emergency dredging. The

document never presents operational triggers for when emergency dredging would occur. The main report indicates that there are four dredges capable of working in winter (p. 3-111), but these dredges are not mentioned earlier, when it was presented that only one or two dredges are available in the short term. A discussion of emergency dredging history, success in other areas, and a description of the equipment available is warranted. The analysis considers long-term O&M costs of dredging, but does not explain the criteria used in the calculation estimates. There is no mention of any historic environmental impacts from the dredge operations, such as spills. If spills have occurred, data should be presented.
Significance – Medium:
Additional information on dredging may enable better analysis and lead to a long-term reduction in dredging costs and the development of a contingency plan to successfully avoid navigation impacts.
Recommendations for Resolution:
1. Develop a paragraph on dredging in the main report that specifies clearly what the maintenance dredging program has been, rates, and frequencies, and if they are scheduled or "as needed." Present all the historic maintenance costs, schedules, and frequencies. 2. Provide a detailed history of emergency dredging with success and failures and costs. 3. Add information to specify what rate of shoaling requires emergency dredging compared to scheduling maintenance dredging activities. 4. Present the criteria used in the calculations of dredging O&M costs. 5. Provide any information on historic spills related to dredging operations.

Comment 17:
The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
Basis for Comment:
Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition. A condition assessment of each jetty structure should be conducted through a combination of visual inspection (stone size, gradation, slope defects, stone defects, loss of armor stone, core exposure, etc.) and evaluation and comparison of historical electronic surveying results (single beam, multi-beam, or side scan sonar data). These elements will provide the basis for determining the present condition, assess risk of current condition to failure, and help classify structure along various reaches of each jetty. These data would enable better assessment of vulnerabilities, analyzing why some areas in the jetty have maintained without repair and other areas have needed multiple repairs. A better understanding of these dynamics may reduce O&M costs over the long term. Rubble-mound structures have a tolerance for deterioration before suffering catastrophic failure. A thorough understanding of current and historical structure condition is critical to developing an estimate of the mechanisms causing failure, establishing the timeframe for catastrophic failure, and conducting maintenance/repair work. The SRB model evaluation of alternatives using the base condition depends upon an adequate understanding of current jetty conditions and corresponding impact on estimated future repair and maintenance. The current SRB analysis is based on a “hindcasting” of jetty performance relative to historical performance, but without consideration of the details of condition and causes of failure. The current and historical condition relative to structural and functional rating should be conducted following USACE procedures (USACE, 1998) to establish the baseline conditions for the SRB model analysis. Evaluation of stone source and quality relative to length of service on the structure should be conducted as part of the jetty condition assessment.
Significance – Medium:
A detailed description of the current jetty structure as part of a condition assessment is necessary to understand the accuracy of the SRB model.
Recommendations for Resolution:
1. Conduct a detailed condition assessment of each jetty structure, including visual inspection and historical survey comparison. 2. Compare historical survey data for the validation of interpreted historical conditions and corresponding perceived modes of failure. Incorporate results into the development of baseline conditions for the SRB model. 3. Use a condition rating system such as that outlined in the USACE Manual REMR-OM-24 (USACE, 1998) for evaluation of current condition. Assess both the structural and functional condition of the structures and incorporate the results into the SRB model analysis.

4. Incorporate the results of the condition assessment into Section 1.4, description of project history.
5. Provide an additional description of existing condition in Section 1.4 and 3.3.2 of the main report, including the service life of stone sources used for previous repair and maintenance activities.
6. Based on the results of the condition assessment, the relation between the stone sources reviewed (in Appendix B, Section 5) and the corresponding observed service life of that stone should be discussed and incorporated in the SRB analysis.

Literature Cited:

USACE (1998). Condition and Performance Rating Procedures for Rubble Breakwaters and Jetties. REMR Management Systems—Coastal/Shore Protection System Devices. Technical Report REMR-OM-24, U.S. Army Corps of Engineers, Washington, D.C.

Comment 18:
The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.
Basis for Comment:
Causes of jetty head scour have not been sufficiently investigated. Tidal shoal and outlet channel geomorphic processes should be further evaluated and analyzed to ensure that proper jetty head repair measures are selected. The mechanisms causing the "scour holes" and undermining of the jetty in the vicinity of the jetty tips (North Jetty and Jetty A) have not been sufficiently analyzed for selection of the jetty head repair measure. Figure A1-32 indicates a progressive erosion of ebb tidal shoals in the vicinity of the North Jetty (between Stations 60 and 90) undermining the south toe of the structure. The report understates the situation when it notes (Appendix A1, p. 28), "If the jetty foundation washes away, jetty reconstruction is problematic." A solid understanding of the environment and bathymetry changes is essential for development of a reliable design alternative. Spur groins installed along the south slope of the North Jetty will assist in addressing scour generated by localized currents, but will not provide protection from overall MCR tidal shoal and channel morphological changes. Continued ebb shoal erosion and potential tidal channel movement could undermine the head of the proposed offshore spur groins (located near Stations 90 and 70). It seems likely that scour holes are related to the observed jetty tip recession. The 100 foot deep scour hole at the end of Jetty A is particularly alarming from a structural design perspective. Equally alarming is the discussion of "Vertical scour along the toe of the MCR jetties has exceeded 10 meters in some reaches" (Appendix A2, p. A2-11). If there really is, or was, a more than 30 foot high underwater scarp in places along the toe of the jetties, then more investigation is warranted. Figures showing typical sections often do not extend to the toe of slope, and show details that aren't feasible, such as rock limits ending in a small angle without an engineered toe. (See Appendix A1, Figure A1-258). Strategies to deal with scour, especially at the jetty tips appear undeveloped. Design features could include scour blankets, launched toes, or a program of regular fill using dredged material.
Significance – Medium:
Inadequate evaluation of the geomorphic processes responsible for the deterioration at the jetty tips (North Jetty and Jetty A) could lead to an incorrect approach to rehabilitation of those areas of damaged structures.

Recommendations for Resolution:

1. Conduct a more detailed evaluation of historical geomorphic changes in the outlet channel and shoals in order to evaluate tidal shoal erosion and tidal channel migration. Comparative analysis of historical bathymetric surveys would be helpful in developing a better understanding of historical trends and associated correlation with jetty structure historical damage, failure, and repair activities. Additionally, use historical geomorphic change analysis and hydrodynamic analysis to estimate long- term changes and impacts to the North Jetty and Jetty A to formulate jetty head rehabilitation alternatives and development of design criteria.
2. Do not limit the jetty repair preliminary designs to the footprint of the authorized jetties. Evaluate scour protection alternatives extending past the jetty tips.
3. Draft plans, profiles, and sections at this level of design using suitable software, such as AutoCAD® or MicroStation®. Microsoft Excel® is not an adequate substitute for drafting software.
4. Draft the jetty design typical sections to scale and extend past the scour holes and navigation channel.
5. Conduct a subsurface geotechnical investigation to obtain the geological properties needed to verify or design an adequate foundation.

Comment 19:
Risk thresholds for selected alternatives are not clearly defined.
Basis for Comment:
Risk thresholds are used in repair frequency predictions as triggers for maintenance response and subsequently in maintenance cost predictions. The frequency of reaching degradation thresholds is predicted by risk thresholds. Combining degradation thresholds with repair costs (minor vs. major) can also be used to determine the threshold for triggering maintenance actions, balancing multiple small repairs against the cost of a single major repair. The Major Rehabilitation Evaluation Report includes extensive discussions of risks related to different portions of the project; however, while this discussion of risk is extensive, defined thresholds are not presented in the document. It is to be expected that the risk (probability) of surpassing thresholds may vary among alternatives in both configuration (number and placement of spurs, jetty length) and in cross sections considered. The risk associated with each alternative considered should be assessed based on materials, cross sections, supporting geological features, currents, and storms. It is also proper procedure to examine how the risk of one design component may be altered by the inclusion or exclusion of a second design component.
Significance – Medium:
Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected.
Recommendations for Resolution:
1. Define risk thresholds for alternatives, including source of risk and effect of exceeding the threshold.

Comment 20:
It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
Basis for Comment:
Project life-cycle cost analyses should consider the risk of construction cycle and operational cycle downtime, which does not appear to be included. However, risks cannot be evaluated without understanding the level of uncertainty associated with the SRB model result. The uncertainty associated with actual future conditions, which may deviate from the modeled future conditions, is not apparent. The SRB model includes 600 variables (Section 9, p. A2-91) each of which has a data set which can be expected to reflect an associated variance. Depending on the calculation stream, these variances, applied geometrically, will lead to accumulated statistical errors and uncertainties. These cumulative internal variances can be expected to result in high uncertainty in the output of the SRB model, which should be considered in the evaluation of alternatives.
Significance – Medium:
Potentially wide error bars (uncertainty) may compromise life-cycle maintenance and repair schedules.
Recommendations for Resolution:
1. Quantify and explain the uncertainty (i.e., error bars) associated with each variable when analyzing processes that involve a chain of events. 2. Identify, analyze, and define errors that may accumulate to assess model reliability.

Comment 21:

The model output parameters and wave height components are not clearly explained and supported.

Basis for Comment:

The meaning of the following SRB model output parameters is not clear:

- Functional Reliability
- Structural Reliability
- Probability of Unsatisfactory Structure Performance.

For example, the main report (Section 3.6.1, p. 3-43) includes the following: "Functional reliability is the likelihood that a structure will satisfactorily perform its intended function within a given time interval. Functional reliability is derived by combining structural reliability metrics with metrics that describe the present structure cross-section configuration." One difficulty is that the understanding of "Functional Reliability" requires first understanding "structural reliability metrics", (which are not to be confused with "metrics that describe the present cross-section configuration"). However, the "structural reliability metrics" are not clearly defined either. A word search of Appendix A2 for the term "Structural Reliability" does not reveal a set of equations for calculating the parameter or a clear explanation.

Similarly, much of the SRB model includes terminology and variables that are hard to understand. For example, Table A2-12, Jetty Maintenance Thresholds, (p. A-60) consists of numbers and parameters not connected to anything that has a physical meaning. Conventional calculations and metrics such as volumes, areas, and depths are parameters with physical meaning that would improve the understanding of the SRB model. Understanding the SRB model outputs would be improved with graphics that are connected to parameters with physical meaning.

The wave height component of the SRB model is not supported by standard coastal engineering practice. Progressive jetty damage in the SRB model is based on a stochastic time series of wave heights, which is derived from "An ensemble of 52 storm events … recorded at NDBC buoys… during 1998 to 2008." It is unclear why only 10 years of buoy data were used when a longer record of more than 17 years with gaps removed is available (Appendix A1, pp. 34 and 37). It is also not certain that extreme wave height events were properly included in the SRB model process. It is common industry practice to test a coastal engineering design using a specific design environmental criterion, such as the 100 year return period wave height.

Significance – Medium:

The model parameters that compare alternatives lack a physical meaning, such as a volume of rock or depth of scour. It is therefore difficult to verify, calculate, or evaluate whether the parameters used or model results are reasonable.

Recommendations for Resolution:
1. Explain and demonstrate how the model output parameters relate to physical performance measures, with graphics or figures. 2. Measure jetty damage and performance with conventional calculations, and commonly applied metrics, for example: a. Volume of sediment entering the navigation channel, or dredge volume, b. Depth or volume of scour at the jetty toe c. Volume or area of armor rock displaced from the jetty. 3. Test the design against a specific storm event, such as the 100 year return period event. 4. Calculate the return period of extreme events using the complete record of measured offshore wave data.

Comment 22:
The culvert installation details, as well as potential impacts, need further clarification.
Basis for Comment:
The Major Rehabilitation Evaluation Report states that the existing culvert has increased scour and adversely affected the North Jetty, and that it will be relocated. There are a few sentences in the main report and in Appendix D that mention the culvert, but there is not enough information provided in the main report to determine if there will be any potential impacts from the new discharge location. The table at the end of Appendix D provides the most detail anywhere in this report regarding the culvert relocation. On p. 6-6 in the main report there is a sentence stating work will begin in 2014 to install a culvert to divert overland flow to another area that will not impact the North Jetty root stability. While this sounds like a reasonable approach to protect the North Jetty, more information is needed to clarify the impact such as the source of the water, an assessment of the water quality, and an estimate of the flow rate involved. Without knowing the exact new location, it is not possible to assess the potential environmental impact of relocating this water flow.
Significance – Medium:
More detailed information on the new location of the culvert as well as water quality, flow rates, and source of the water is necessary to determine the environmental impact of the relocation.
Recommendations for Resolution:
1. Add one paragraph in the main report that addresses the culvert relocation. 2. Present any available data on the water quality, flow rates, and water source of water discharged through the culvert. 3. Provide the specific location planned for new culvert.

Comment 23:
The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
Basis for Comment:
The terms “project life” and “period of analysis” are not defined or differentiated, and the project base year varies throughout the report: • In the economic spreadsheet models, the NPVs are calculated for differing periods of analysis (2009-2070 for South Jetty, 2008-2070 for Jetty A, and 2008-2070, 2008-2057 and 2008-2069 for the North Jetty); whereas the AACs are based on a 50 year period of analysis. • The period of analysis extends 50 years beyond the base year of 2011 when discussing sea level rise (pp. A1-38 and A2-68). • The period of analysis for future condition simulations is 64 years (2006 to 2970) for the North Jetty and Jetty A and 63 years (2007 to 2070) for the South Jetty (p. A2-78). • The AAC is calculated using an amortization factor applied to the present year cost stream from the NPV implementation year (2006/2007) to 2069 (p. A2-51). • The base year of the economic analysis is not identified in Section 2 or Appendix C, but is stated as 2014 elsewhere in the report (pp. ES-3 and A2-78). • Within the SRB model, the base year is stated as 2011 when discussing sea level rise (pp. A1-38 and A2-68). • Within the SRB model, the base year for NPV cost discounting is 2006 for the North Jetty and Jetty A, and 2007 for the South Jetty (p. A2-51).
Significance – Low:
Inconsistencies in terminology and periods of analysis can lead to misunderstanding of findings and results.
Recommendations for Resolution:
1. Define and differentiate between the terms “project life” and “period of analysis.” 2. Revise the report to eliminate inconsistencies between the varying periods of analysis. 3. Use a consistent base year throughout the analysis, and revise the report to reflect consistency. 4. Revise Section 2 and Appendix C of the report to state the year that is considered to be the base year, the length of the period of analysis, and the calendar years that are included in the period of analysis. 5. Provide definitions of all terms in a Glossary.

Comment 24:
Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.
Basis for Comment:
Data presented throughout the report have inconsistencies that should be corrected. The following are examples of inconsistencies in values for cargo tonnages, vessel trips, and value of cargo: • Page ES-1 – cargo on the MCR is 45 million (M) tons and 3,500 vessel crossings based on 2008 Waterborne Commerce Statistics Center data. These data are not cited in the body of the report. • Page 1-2 – cargo on the MCR is 40 M tons worth $17 billion, with 12,000 commercial vessels navigating the MCR annually. • Pages 2-1 and C-1 – cargo on the MCR is 40 M tons valued at $17 billion based on a 2009 Pacific Northwest Waterways Association (PNWA) factsheet cited in Appendix C. • Pages 1-4 and C-4 – cargo on the MCR is 32 M tons in 2003 and projected at 43 M tons in 2020 based on 2005 Center for Economic Development and Research (CEDER) data, cited as a footnote in Appendix C. • Page C-5, Table C-1 – 5,364 total vessel trips on the MCR based on 2005 Waterborne Commerce Statistics Center data. • Page A1-3 – cargo on the MCR is 48 M tons worth $16 billion, with 12,000 commercial vessels navigating the MCR annually. The cargo and vessel trip statistics presented in the report appear to include all traffic on the MCR and Lower Columbia River (LCR). The report assumes all traffic accessing the MCR is dependent on the MCR jetties. The without-project condition channel depths are not adequately described. The cargo and vessel trips that would be impacted by the jetties, that is, the portion of the fleet transiting the MCR that would be restricted by the without-project condition channel depths, is not described.
Significance – Low:
Consistent cargo and vessel trip data for the MCR are needed in order to develop an understanding of the significance of the jetties.
Recommendations for Resolution:
1. Describe the cargo tonnages, vessel trips, and value of cargo consistently throughout the report, or supply an explanation of the differences and why various data sources were used. 2. Describe the portion of the fleet accessing the MCR that is dependent on the jetties (i.e., what are the without-project condition channel depths and what portion of the fleet transiting the MCR would be restricted by the without-project condition channel depths).

Comment 25:
Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.
Basis for Comment:
Inconsistencies in terminology can make understanding the project difficult. Commonly used terms in the document, such as "failure," are not clearly and qualitatively defined. Phrases such as "close to failure" appear frequently, in a qualitative sense, but without an understanding of how much jetty damage, if any, constitutes a "failure." Another example is in the SRB model where "fix-as-fails" repairs are described as, "To defer jetty maintenance for as long as possible, the jetty is maintained close to the margin of functional loss." The concept makes sense but how the model deals with terms like "as long as possible" and "close to the margin of functional loss" is unclear. Other phrases, such as "scheduled repair" and "rehabilitation" seem to be inconsistent as well. For example, "scheduled repair" includes "head capping" in the executive summary of the main report, but does not include "head capping" in some alternatives analyzed by the SRB model.
Significance – Low:
Without clear, consistent definitions of terminology, it is difficult to understand exactly what is being proposed or analyzed and can lead to misinterpretations.
Recommendations for Resolution:
1. Add a Definitions list or Glossary to the document.

APPENDIX B

Final Charge to the Independent External Peer Review Panel
as
Developed by USACE and Submitted to the Panel on December 28, 2010

on the

Mouth of Columbia River IEPR

This page is intentionally left blank.

CHARGE FOR PEER REVIEW

Members of this IEPR Panel are asked to determine whether the technical approach and scientific rationale presented in the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report are credible and whether the conclusions are valid. The Panel is asked to determine whether the technical work is adequate, competently performed, properly documented, satisfies established quality requirements, and yields scientifically credible conclusions. The Panel is being asked to provide feedback on the economic, engineering, environmental, geomorphology, and plan formulation. The panel members are not being asked whether they would have conducted the work in a similar manner.

Specific questions for the Panel (by report section or Appendix) are included in the general charge guidance, which is provided below.

General Charge Guidance

Please answer the scientific and technical questions listed below and conduct a broad overview of the Mouth of the Columbia River ER. Please focus on your areas of expertise and technical knowledge. Even though there are some sections with no questions associated with them, that does not mean that you cannot comment on them. Please feel free to make any relevant and appropriate comment on any of the sections and appendices you were asked to review. In addition, please note the following guidance. Note that the Panel will be asked to provide an overall statement related to 2 and 3 below per USACE guidance (EC 1165-2-209; Appendix D).

1. Your response to the charge questions should not be limited to a “yes” or “no.” Please provide complete answers to fully explain your response.
2. Assess the adequacy and acceptability of the economic and environmental assumptions and projections, project evaluation data, and any biological opinions of the project study.
3. Assess the adequacy and acceptability of the economic analyses, environmental analyses, engineering analyses, formulation of alternative plans, methods for integrating risk and uncertainty, and models used in evaluation of economic or environmental impacts of the proposed project.
4. If appropriate, offer opinions as to whether there are sufficient analyses upon which to base a recommendation.
5. Identify, explain, and comment upon assumptions that underlie all the analyses, as well as evaluate the soundness of models, surveys, investigations, and methods.
6. Evaluate whether the interpretations of analysis and the conclusions based on analysis are reasonable
7. Please focus the review on assumptions, data, methods, and models.

Please **do not** make recommendations on whether a particular alternative should be implemented, or whether you would have conducted the work in a similar manner. Also please **do not** comment on or make recommendations on policy issues and decision making.

Comments should be provided based on your professional judgment, **not** the legality of the document.

1. If desired, panel members can contact one another. However, panel members **should not** contact anyone who is or was involved in the project, prepared the subject documents, or was part of the USACE Independent Technical Review.
2. Please contact the Battelle Deputy Project Manager (Richard Uhler, uhlerr@battelle.org) or Project Manager (Karen Johnson-Young, johnson-youngk@battelle.org) for requests or additional information.
3. In case of media contact, notify the Battelle Project Manager immediately.
4. Your name will appear as one of the panel members in the peer review. Your comments will be included in the Final IEPR Report, but will remain anonymous.

Please submit your comments in electronic form to Richard Uhler, uhlerr@battelle.org, no later than January 31, 2011, 5 pm EST.

Independent External Peer Review
Columbia River at the Mouth, Oregon and Washington
Major Rehabilitation Evaluation Report

Final Charge Questions

GENERAL QUESTIONS

1. To what extent has it been shown that the project is technically sound, environmentally acceptable, and economically justified?

2. Are the assumptions that underlie the economic, engineering, and environmental analyses sound?

3. Are the economic, engineering, and environmental methods, models, and analyses used adequate and acceptable?

4. In general terms, are the planning methods sound?

5. Are the interpretations of analysis and conclusions based on the analysis reasonable?

MAIN REPORT

SECTION 1.0 -- INTRODUCTION

6. Is the project's purpose and scope complete and understandable?

7. What other information, if any, should be included in this section?

8. Has adequate public, stakeholder, and agency involvement occurred to determine all issues of interest and to ensure that the issues have been adequately addressed to the satisfaction of those interested parties?

9. Comment on the extent to which the existing conditions are clearly and adequately described.

10. Comment on whether the information presented supports the problem identified under the base condition.

SECTION 2.0 -- ECONOMIC CONSIDERATIONS

11. Has the base condition, without-project condition and summary of costs and benefits been adequately described, analyzed, and explained?

12. Does the National Economic Development (NED) Plan contrast to the base condition?

13. Is it clearly explained why navigation benefits were not analyzed?

SECTION 3.0 -- ENGINEERING CONSIDERATIONS

14. Is the description of functional and structural reliability clear and reasonable?

15. Was the Stochastic Risk-Based Life Cycle Simulation (SRB) model used in an appropriate manner? Is the description of how the model functions, the relative influence of model parameters and model calibration process clear and logical?

16. Comment on the repair and rehabilitation alternatives. Is the description of the different plans clear and distinct?

17. Comment on the engineering features for alternatives. Do the plan descriptions clearly indicate which features are incorporated into the various plans?

18. Comment on the evaluation of engineering features. Is the scope, function and analysis of the engineering features clearly described?

19. Comment on the general alternative development approach. Does the alternative evaluation presented follow USACE guidance?

20. Comment on the engineering evaluation of alternatives. Are the plans adequately evaluated based upon their engineering merit?

21. Has the sediment analysis been adequately performed and documented to support the movement of material that occurs during a breach event?

22. Has the analysis been adequately performed and documented to support reductions in channel maintenance dredging?

23. Does the analysis adopt adequate risk thresholds for different alternatives and are such thresholds uniformly consistent?

24. Are potential life safety issues accurately and adequately described under existing, future without project, and future with project conditions?

25. Has the rationale for head capping locations at each jetty been adequately explained?

26. Has the basis for the number and location of spur groins been adequately explained?

SECTION 4.0 -- ASSESSMENT OF ALTERNATIVES

27. Does plan selection reflect a full range of design alternatives?

28. Are the problems and opportunities appropriately defined and addressed in this study?

29. Are there any other constraints or objectives that should be considered as part of the project that would be important to reaching the projects final goals?

30. Do the alternatives adhere to the USACE Plan Formulation Criteria? Do they appropriately address the needs and objectives of the project? What additional information, if any, should be discussed?

31. Comment on the completeness of the project-specific criteria used in the comparison of alternatives.

32. Was the NED Plan appropriately identified and selected?

SECTION 5.0 -- ENVIRONMENTAL CONSIDERATIONS

33. Comment on the completeness of the environmental documentation. Have all National Environmental Policy Act (NEPA) requirements been satisfied?

34. Have the water resources in the project area been accurately described?

35. Comment on the thoroughness and accuracy of the marine and estuarine resource information presented.

36. Comment on the overall discussion of environmental effects due to the project.

37. Comment on the adequacy of available information used to characterize wetland resources within the study area.

38. Comment on whether the special status species and resource areas in the project area have been accurately described.

39. Comment on the adequacy of the environmental and without-project condition summaries in terms of data quality, timeliness of the data, and breadth of information covered.

SECTION 6.0 – CONSTRUCTION AND COST ESTIMATE

40. Comment on the overall adequacy and reasonableness of the detailed cost estimates.

41. Comment on the extent to which the cost summary is complete and consistent with the detailed analyses shown in this section.

42. Is the construction schedule adequate for completion of the recommended activities?

SECTION 7.0 – RECOMMENDATIONS

No questions.

SECTION 8.0 – REFERENCES

No questions.

APPENDICES

Appendix A1 – Coastal Engineering

43. Does Appendix A1 describe the coastal engineering history and challenges specific to the Mouth of the Columbia River?

44. Does Appendix A1 contain adequate information to assess coastal engineering at the Mouth of the Columbia River?

Appendix A2 – Reliability Analysis, Event Tree Formulation and Life-cycle Simulation

General Questions

45. Is the purpose of the model clearly defined?

46. Is the model diagram easily understood?

47. Does the model follow a logical programming path?

48. Does the model adequately capture and evaluate all of the relevant variables?

49. Can the model as described achieve the stated purpose?

50. Does the model accurately describe (model) repair activities and sequences? Is it modeling the repair activities similarly to how the repairs will be sequenced and performed?

Technical Quality

51. Comment on the overall technical quality of the model.

52. Is the model a realistic representation of the actual system?

53. Are the analytical requirements of the model properly identified?

54. Does the model address and properly incorporate the analytical requirements?

55. Are the assumptions clearly identified, valid, and do they support the analytical requirements?

56. Comment on the ability of the model to calculate benefits for total project life.

57. Has the design wave height of 55 feet been appropriately calculated and documented?

58. Have the waves generated by the model been validated against observed wave data?

Usability

59. Comment on the model's usability.

60. Are the model results easily understood?

61. Do the model results support the project objectives?

62. Is user documentation available and complete?

63. Is the model transparent and does it allow for easy verification of calculations and outputs?

Appendix B – Geotechnical Studies

64. Does the background information adequately describe the geologic history and conditions at the Mouth of the Columbia River and surrounding area?

65. Are all of the site specific and distinct geological features relevant to the project described and appropriately addressed in the engineering design?

66. Were risk and uncertainty sufficiently considered?

Appendix C – Economic Analysis

67. Comment on the assumptions and forecast methods used to calculate project benefits.

68. Comment on the reasonableness of the scenarios used to calculate benefits.

69. Comment on the method used to calculate the National Economic Development (NED) benefits.

70. Comment on the assumptions used in the calculation of present value of benefits.

71. Comment on the extent to which the NED benefits summary is consistent with and justified in the economic analysis.

Appendix D – Environmental Documentation

72. Comment on the ability of the proposed mitigation plans to address adverse impacts from the project.

73. Are the conclusions regarding the type and projected magnitude of adverse impacts to resources within the study area reasonable?

74. Comment on the appropriateness and comprehensiveness of the identified mitigation projects considered for addressing predicted impacts arising from the project.

Appendix E – M-CACES Cost Estimate for Recommended Plan

75. Comment on the overall adequacy and reasonableness of the detailed cost estimates.

76. Discuss the appropriateness of the explicit or implicit assumptions that are included in the cost estimates and whether assumptions are adequately addressed.

77. Comment on the extent to which the cost summary is complete and consistent with the detailed analyses provided in the study report.

Appendix F – Project Management Plan

No questions.

Appendix G – Schedule of Fully Funded Project Costs

No questions.

FINAL OVERVIEW QUESTION

78. What is the most important concern you have with the document or its appendices that was not covered in your answers to the questions above?

Subj: Review and Recommendations for Life-Cycle Simulation Model for the Jetties at the Mouth of the Columbia River, Oregon and Washington
Contract No. W912PL-08-D-0016; Task Order No. DT03

Dear Mr. Brodesser:

The purpose of this letter is to provide the results of an assessment of the Stochastic Reliability Based lifecycle simulation model (SRB) which evaluates maintenance strategies for the rubble mound jetties located at the Mouth of the Columbia River (MCR). Moffatt & Nichol (M&N) is under contract with the U.S. Army Corps of Engineers (USACE), Portland District, to prepare this review and provide recommendations for proceeding towards meeting the requirements of an approved planning model as defined by *EC 1105-2-412 - Assuring Quality of Planning Models*.

BACKGROUND

The SRB model is a computer simulation MATLAB® code that stochastically evaluates the environmental loading affecting each of the MCR jetties, and relates structural response (cross-section evolution) of each jetty to functional performance. The structure response is evaluated in terms of cross-section area change (loss) over time due to jetty degradation. Jetty repairs are activated within the SRB model after the jetty cross-section is reduced below a specified threshold value. Jetty repairs are calculated in terms of the tonnage of armor stone required to re-establish the jetty cross section to its standard dimensions. Life-cycle costs estimated by the SRB model include jetty repair and incremental dredging attributed to jetty degradation and loss of function. Because life-cycle costs are estimated using stochastic methods, their realization can be considered probabilistic. Although reliability is also calculated within the SRB model, reliability is not used to simulate structure response and related consequences (life-cycle cost). Reliability is modeled as a function of repair and maintenance, and is used as a supplemental metric to inform on overall jetty performance.

As part of the USACE review process, the model underwent an Independent External Peer Review (IEPR) and was subject to Headquarters (HQUSACE) review for approval of use. The IEPR panel had four highly critical comments regarding the SRB model; subsequently, the panel did not approve the model for one-time use.

The M&N approach towards assessing the model is based on a tiered approach as follows:

- Assessment of the critical IEPR comments for possible resolution;
- Review overall modeling approach to verify inclusion of all critical mechanisms;
- Review formulation of the critical mechanisms;
- Review model documentation for adequacy in describing mechanism formulations;
- Review implementation of the mechanism formulation in the MATLAB® code;
- Review calibration/validation of processes incorporated in the model; and
- Preliminary review of MATLAB® code for efficiency and transparency.

This evaluation focuses solely on the model approach for the North Jetty as it is assumed the overall approach will be similar for the South Jetty and Jetty A. Also, there has been some modification of the North Jetty model to address ATR Comments so it presumably represents the latest and best formulation.

The results of our assessment of the model and our conclusions and recommendations are described in the following sections of this letter. The evaluation of the IEPR comments is discussed first since appropriate resolution of these comments is critical for model approval. The remainder of the report deals with the assessments of the overall approach, the MATLAB® code, and the model documentation. The conclusions and recommendations are in the last section.

EVALUATION OF IEPR COMMENTS

There are four significant comments from the IEPR that require resolution if the model is to be accepted as an authorized planning model. Each of these comments is addressed in this section.

Comment # 2: The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.

This comment addresses the sediment transport into the navigation channel as a result of a breach in the Jetties. The breakwater has breached in the past which has allowed sediment transport into the navigation channels, but the quantities and mechanisms have not been well documented. The disagreement between the Coastal Modeling System (CMS) Model Study is also of concern, although clearly the CMS model evaluation utilized a time scale inconsistent with the actual processes. The CMS model simulated the breach over a period of 6.5 days whereas the time frame for the observed shoaling related to the breach occurrence was on the order of months. This time frame difference would explain the difference in shoaling magnitude.

The recommendation from the IEPR that a more thorough investigation of the shoaling processes be incorporated is likely inconsistent with the time frame for the model implementation. After evaluation of the costs associated with the breach occurrences, a more appropriate approach may be to incorporate the emergency repair to the Jetty and disregard the dredging costs associated with the breach. This approach would satisfy the bulk of the IEPR comment. If the breach is considered in a planning scenario, some reasonable cost could be incorporated in the planning outside of the model framework.

Comment # 4: The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.

This IEPR comment is a blanket statement which leaves very little room for a response. However, it appears that there is a clear misunderstanding about what the model does and how it performs. The primary response to this comment would be to provide more transparency in the model formulations and how these formulations are appropriate for the MCR jetties. The formulations need to be validated to illustrate confidence in the predictive capability of the model based on historical jetty maintenance experiences.

It should also be emphasized that the model should be considered as a comparison tool and that it does not make the final decision. The IEPR review seemed to believe the model concluded with a decision which is incorrect. Engineering and economic judgment is still required once the model evaluation of alternatives is completed.

The portion of the comment related to armor rock breakage and slip circle failure is beyond the scope of the model and the comment should be considered invalid. The model is based on the assumption that the bulk of the damage is related to coastal processes and that these processes are included in the model with additional damage sources accounted for in the selection of the damage function calibration factor. This comment can also be addressed similar to the response to Comment #8 below.

Comment # 7: The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.

The resolution to this comment is to clarify that the model is for a 50-year planning horizon and that all design criteria should be based on 100-year return interval. All other references to various 50-year periods should be clarified within the documentation.

Comment # 8: The models and analyses of jetty failure do not include all significant processes.

This comment suggests that additional geotechnical data should be gathered in the vicinity of the jetties, specifically boring data. Based on discussions with the Portland District personnel, we understand the generally feeling that there is adequate geotechnical data for the design of the jetties. This comment is best addressed by documenting and explaining the extent of the geotechnical data that has been assembled for past maintenance efforts. It can also be pointed out that the predominant processes impacting the stability of the jetties is related to the coastal processes more than geotechnical issues based on historical experience with the jetties.

To a great extent, the soil properties related to scour are addressed in the model based on calibration against historical observations and this implicitly considers this facet of the geotechnical factors.

ASSESSMENT OF MODEL APPROACH

Model approach was reviewed with a general purpose to identify fundamental issues and discrepancies in the model. The main comments are provided below.

1. The model calculations and most of governing input parameters were defined with a hard coded jetty segment size of 100 ft. It is understood, that the segment length was selected as a typical length of repairs and damage. Greater flexibility in the model application and calibration could be achieved if the internal segment size for calculations is made adjustable.

2. The present approach defines one year as overall time step in the model and calculates damage to each segment cumulatively based on the number of storms in each year. It would be more logically correct to iterate over a sequence of storms in each year and then calculate damage to the jetty segments in each storm. That would allow more flexibility to evaluate damage on any different time step and, if needed, on a storm-by-storm basis.

3. The number of storms is limited to 52 historically observed storms, for which measured storm parameters are applied. The selected set of storms represents the general population of storms in the area sufficiently well. However, use of preselected storms and water levels in Monte Carlo simulations may impose some limitation in the analysis. During the storms which have a potential to damage the jetties wave heights at the structures are limited by depth. Therefore, wave direction (which governs distribution of wave heights along the jetties) and more importantly water level are the main parameters which control the level of damage and distribution of damage along the structure. The model presently utilizes only three water levels for each storm, while more variability could be added to water levels in the MC simulations. Additionally, it would be advantageous to provide a guidance on how to define a set of synthetic storm conditions which represent the population of storms in the area where detailed observations of the storms is not available.

4. The wave parameters for segment damage function were extracted from STWAVE model output. It is expected that the wave parameters vary along each segment of the jetty and for every segment a single set of parameters (wave height, period, etc) was identified. A description of how to select these values from the STWAVE results would be beneficial.

5. Tidal currents, river floods and storms cause significant morphological changes around the jetties such as scour, channel migration, and shoal evolution. These changes were approximated in the model by historic trends. It would be advantageous to include the possibility to modify these trends as a part of “what if” alternative simulations. For example, what if scour at the toe of the North jetty expanded and resulted in additional damages.

6. The deterministic and random variables should be clearly defined in the model. The random variables are defined in the beginning of each MC simulation. The deterministic are either preset or calculated using formulas based on other variables.

7. Formulas for static (toe scour and slope failure) and dynamic (wave breaking and overtopping) effects on jetty damage needs to be verified. These formulas define the governing procedure of each jetty's response to a storm. Accuracy of these formulations is crucial. Most formulas from accepted procedures deal with prediction of damage to a breakwater from a single storm under the assumption that the breakwater keeps the initial profile shape. If the jetty sustains damage from one storm to another, the profile will adjust by stone displacements. Currently, the model accumulates damage from multiple storms in one year without considering adjustment of the structure between the storms. It is assumed that the second storm will have the same damage as the first one, which may lead to overestimation of the total damage.

8. The model utilizes a simplified parameterization of the cross-section profile of the jetty. The cross-section is divided at −5 ft MLLW into top and bottom layers. The top layer is affected by dynamic damage, and the bottom layer is affected by static damage. Since damage is calculated as loss of area, additional assumptions were applied to the slopes, top width and jetty height to match the remaining area. It is clear that the resulting profile is only an approximation of the actual damaged profile. A clear explanation of the process of profile adjustment would help in understanding how stone volumes in the top and bottom layers are calculated, as well as reused and lost stone.

9. Approximation of jetty damage from a storm is the key element of the entire model. The damage functions were defined from lab tests for selected conditions, such as normal profile, damaged profile, etc. They represent relationships between wave heights and lost cross-section areas as A = f(H). The damage functions were calibrated in the model by using shift in wave height as $A = f(H - H_{shift})$, which essentially moves the threshold when damage begins. It was identified that each damage function could have its own shift parameter, but only if that function was utilized in the calculations. It is possible that damage functions for a new configuration of the jetty may be slightly different, which make it difficult to select the appropriate shifts for forecast conditions under new alternatives.

10. Shoreline erosion/accretion is approximated in the model from the historic trend which is a reasonable approximation. Additional flexibility in the model could be achieved by allowing easy modifications to these trends or specifications of new ones based on the jetty repair alternatives. For example, if an alternative can cause acceleration in shoreline erosion/accretion. It is also very conservative to assume that <u>all</u> eroded sediments are transported into the navigation channel.

11. Two independent components, financial and structural, should not be combined into one MC simulation. It would be better to separate them into two MC analyses by making

structural components (storms, damages, and repairs) completely independent of financial components (price for repairs and dredging). This should answer the question—what if the storm sequence is the same, but the strategy on the repairs changes, would the jetty reliability be the same? Then results of these MC simulations can be recalculated with variable prices. This second simulation would tell if the prices change, will this affect an earlier decision about the repair strategy?

COMMENTS ABOUT MATLAB® CODE

The comments about the model code are given below.

1. The simulation folder contains many files of different types, including Excel spreadsheets, text files, and MATLAB® binary files. There is no distinct difference between the names of input and output files or perhaps folders to isolate input and output files in different locations.

2. The main input file is called *AA_XLS_new.mat*, where AA is the jetty name. The variables in this file were derived by a preprocessing script from Excel files. There are many variables in the file but no descriptions. Some references can be found by referencing the preprocessing script, but without MATLAB®, there is no easy way to modify the file or check the content.

3. The main model script is called *event_tree_NNN.m*, where NNN is name of the jetty and alternative. The file consists of more than 7300 lines. About 2000 lines are dedicated to plotting and output. This is a very large file to edit and navigate, considering the fact that most modifications to model control variables should be done in that file. Additionally, there are four subroutines which are stored in separate files. None of the scripts include online help or detailed description of the input/output parameters. Some subroutines have more than 20 input variables. The input/output and variable handling is not done in a structured manner.

4. Many variable names reflect the name of the jetty that the routine was developed for. This practice creates unnecessary difficulties for comparing between different versions of the code. For example, it would be difficult to compare codes between NJ and SJ to verify if the two routines work similar.

5. The routines create too many variables which are stored in the same workspace. Some structuring of the variables could potentially help in review of model results.

6. There are too many hard-coded coefficients in the scripts. Many of them are not placed in the same part of the code and are spread throughout the code. The hard-coded coefficients are mixed with process control parameters. This creates difficulties in identification of parameters which can be changed to modify the way MC simulations are performed.

7. There are many parameters which define particular events, for example, *Repair_Crest_el_1939* or *Crest_El_2006*. These variables probably have very little information for forecast mode. Therefore, it is clearly a question if hindcast and forecast modes can be separated into different subroutines, while forcing functions remain the same.

8. The alternatives are implemented within the same main code. The selection is done by setting a single variable *fut* in the beginning of the code. It is not transparent how additional alternatives can be added or existing ones modified. There are numerous IF statements, which seem to depend on the value of *fut*.

9. Some graphical output is created for a jetty segment selected before the MC simulation. There is probably a way to create plots for another segment without the need to rerun simulations, however it is not obvious. Graphical output could be completely separated from the main routine to allow more flexibility in creation of figures without the need to rerun a simulation. This is especially important, since MC simulations give stochastic (variable) results.

COMMENTS ABOUT DOCUMENTATION AND USER'S MANUAL

The *Model Documentation Report* provided a general description of the model background and principal algorithms. Sufficient details were given on the basic model organization, principles of operation, and main input and output. A part of the report named *Model Operation Guide* included some information on the calibration process, model setup, selection of alternatives (repair strategies), and model inputs and outputs. This part was found to be rather brief and in most cases only indicated general locations (a script name or data file) where modifications can be done to allow the user to change inputs into the model. Explanation of the model calibration was not complete. In particular, specific details about how the values of calibration parameters were used in the forecast mode were not included.

Most of input parameters (damage function, STWAVE model output, jetty configurations) were defined in a series of Excel files. However, most of the parameters in these files were self explanatory, and it would be difficult to make significant changes to the model inputs without modifications to the main code of the model. For example, the damage functions were defined by hard-coded variables with fixed sizes. Any changes to the damage function array size would require modification in the corresponding Excel file, preparation script, and the main code. A detailed description of how would be accomplished is not provided.

CONCLUSIONS AND RECOMMENDATIONS

Our overall recommendation is to retain the existing model and make improvements to satisfy planning model approval requirements. The basic premise of the model is sound and a great deal of effort has gone into formulating the important processes impacting the jetties and the maintenance procedures available for jetty repair.

The recommendation to retain the existing model is based on several considerations. The first consideration is the requirement to complete the evaluation of maintenance plan alternatives and recommend the most appropriate plan within the next few months. Several years have gone into the development of this model. Knowing that objectives for the model evolved over this time period, it should not take as long to develop a model from scratch. However, we do estimate that model development from scratch would require at least a year or two including model approval for use in the evaluation of planning alternatives. This time frame does not meet the requirements of the Portland District schedule.

The second consideration for retaining the existing model with improvements is the engineering cost associated with development from scratch. While we have not worked up a detailed cost estimate for a scope of this magnitude, the fee for M&N to do this work would likely be approximately $400,000. Portland District personnel as well as review personnel would also be participating in this project requiring additional engineering costs. Working with the existing model and making the recommended modifications will be significantly less, likely less than half of this budget.

Improvements are required to meet the requirements for an authorized planning model. Specifically, the following improvements should be implemented:

1. Modularize the model code using the existing approaches where they are appropriate. Specifically, separate parts of the code related to the following:

    - Setup of global variables
    - Setup of MC simulation
    - Specification of alternatives
    - Calculation of damage functions
    - Geometry adjustment after damage
    - Creation of output and plotting

2. Validate independent modules based on available literature and previous experience with the MCR jetties. Alternative formulations of the damage functions used in the model should be provided for comparison of model results with alternative published analytical formulations.

3. Calibration results for the model need to be clearly documented. To accomplish this, the calibration process and parameters must be clearly documented within the model and in the model output and reporting. Additional performance metrics can also be extracted from the model results and clearly presented. This will help improve the transparency of the model for those not directly involved with setting up and running the model.

4. During the process of modularizing the existing model, the structure should be changed to allow a single model code capable of evaluating alternatives for all three jetties.

5. Improvements are required in the user interface to allow the user to easily review all input and output parameters. Existing hard-coded parameters should be removed from the model code to provide greater transparency.

6. A well-documented user's manual needs to be prepared to allow qualified modelers to apply the model to evaluate alternatives. The majority of this effort would be improvements to the *Model Operation Guide*.

7. The economic and structural analyses should be separated into independent routines. The economic analysis calculations would be based on the output from structural simulations with an interface between the two models. This approach also permits the use of different economic analysis approaches for a single structural simulation.

8. Additional metrics for evaluating alternatives can be output from the model to assist in the economic evaluation of the alternatives. These include structural and functional reliabilities, stone volumes which were lost, placed, or moved, and others. A facility can be created to easily calculate and output new metrics as needed. These additional metrics will add to the transparency of the model results and go a long way towards gaining approval for the model as an authorized planning model.

9. The shoaling related to jetty breaching should be eliminated while the repair requirements to the jetty section should be retained for the breaching. This recommendation is based on IEPR comments suggesting that it will be difficult to get a professional consensus regarding the appropriate shoaling volume and distribution. As this shoaling volume is relatively small compared to the morphological changes related to jetty tip retreat, the impact to costs in the alternative analysis is relatively minor.

There are two additional issues which are fundamental to an appropriate modeling approach. The first issue is the morphological assessment within the model related to recession of the jetty tips. Decisions regarding future maintenance of the jetties needs to address whether the current location should be retained as the optimal location or whether the tips should be allowed to recede further. The current approach for morphological impacts as implemented within the model does not address this decision. A much more sophisticated morphological modeling approach is required to address this issue. However, given the available time to evaluate the jetty maintenance alternatives and the high likelihood that whatever approach is used will extend controversy of the model applicability, we do not recommend development of a more detailed morphological model at this point. However, this component could be included at a later date when scheduling or application requirements permit.

The second fundamental issue that should be addressed further is the damage functions currently used in the model. The damage functions are fundamental to the model results and therefore their application in the model should be accurate and transparent. An analysis should be performed in order to define the possibility of a clearer approximation for the damage functions derived from physical model results. The calibration process for the shift parameter in the damage functions will also be reviewed with an attempt to improve the calibration process. This task may or may not result in a better damage function specification or calibration parameter selection; however, it will become a part of code modulation and restructuring task and would permit comparison of alternative damage function approaches.

Given the recommended tasks above for model improvements and realizing that time is of the essence in getting the model approved for this application, we estimate that the work to accomplish these tasks would require approximately 3.5 months. If work begins immediately, the project would be completed by approximately mid-January 2012. This work would include getting approval for model use, simulating the currently identified maintenance alternatives, and assistance in preparing the alternatives assessment report.

It has been a pleasure to be involved with this challenging project. We hope to continue to be of assistance with moving this model forward and making it a useful tool for evaluating maintenance strategy alternatives. Please do not hesitate to contact me if you have any questions or concerns regarding our assessment of the model and the potential for application to the MCR jetty maintenance planning.

Sincerely,

MOFFATT & NICHOL

STATEMENT OF WORK FOR
MODIFICATION No. 2

CONTRACT NO. W912PL-08-D-0016, MOFFATT & NICHOL
TASK ORDER NO. DT03, LIFE-CYCLE SIMULATION MODEL SUPPORT FOR THE JETTIES AT THE MOUTH OF THE COLUMBIA RIVER, OREGON AND WASHINGTON

1. BACKGROUND. During Phase 1 of the task order, the AE team assessed the current SRB model architecture, code, and documentation; the three outstanding IEPR comments and Assuring Quality of Planning Models (EC 1105-2-412), and made a recommendation on the most efficient approach to obtain model approval. The AE team was asked to provide details on how to achieve model approval and respond to open IEPR comments by either:

(1) Improve and revise existing model architecture and code;
or
(2) Start over with entirely new planning model

The AE team's recommendation is to improve and revise the existing model code. The team identified nine specific recommendations to improve the model. Those recommendations will be used as the first nine tasks for this modification. Additional tasks will be identified for technical writing, plan formulation and Report Editing.

2. OBJECTIVES. This modification of the task order is for phase II.

During Phase 2 the CENWP's product delivery team will work collaboratively with the AE team to develop the following:

- A fully documented model which has been validated and verified, with input and output files, and a user's manual – meeting the requirement of EC 1105-2-412.
- Clearly defined design criteria and basis for design.
- A range of alternatives leading to a least-cost plan.

The AE Team members under this task order shall possess the following skill sets:

- MATLAB programmer with 5 years experience.
- Senior coastal engineer with 20 years experience in the design of coastal structures.
- Economist with 10 years USACE plan formulation experience (Phase 2).

3. MANDATORY SERVICES TO BE PROVIDED.

a. <u>Task 1: Modularize the model code</u> The model code architecture will be modified utilizing the existing modeling approaches where they are appropriate, and separating the parts of the code related to the following:

- Setup of global variables

- Setup of Monte Carlo simulation
- Specification of alternatives
- Calculation of damage functions
- Geometry adjustment after damage
- Creation of output and plotting

b. Task 2: Validate Independent modules The independent modules that are established in Task 1 will be validated for functionality and accuracy utilizing available literature and previous experience with the MCR jetties. Alternative formulations of the damage function used in the model will be developed by the AE team for comparison of model results with alternative published analytical formulations.

c. Task 3: Document Calibration Results The AE team will calibrate the revised model clearly documenting the calibration process and the parameters used in the model and in the model output and reporting. Additional performance metrics will also be extracted from the model results and clearly presented when feasible. The goal of documenting the calibration process and parameters used is to provide transparency of the model functions for reviewers not directly involved with setting up and running the model.

d. Task 4: Develop Single Model Code for all Three Jetties During the process of modularizing the existing model code, the structure will be changed to allow a single model code capable of evaluating all three jetties.

e. Task 5: Improve User Interface. Develop a user interface that will permit the user to easily review all input and output parameters. Existing hard-coded parameters will be removed from within the model code to provide greater transparency of how individual parameters affect model output.

f. Task 6: Prepare Users Manual. A well documented user's manual will be prepared in order to allow qualified modelers to apply the model to evaluate alternatives. The majority of this effort will be improvements to the existing Model Operation Guide.

g. Task 7: Separate the Economic and Structural Analysis. The economic and structural analysis will be separated into two independent routines. The economic analysis calculations will be based on the output from the structural simulations with an interface between the two models. This approach will permit the use of different economic analysis approaches for a single structural simulation.

h. Task 8: Provide the Capacity to Output Additional Metrics from Model. Create a facility to calculate and output additional metrics as needed. New metrics may include structural and functional reliability, stone volumes which were lost, placed or moved and others not yet identified. Additional metrics will be used to enhance the transparency of the model results with the intent of facilitating model approval.

i. Task 9: Remove Breach Shoaling. The in-channel shoaling volumes and required additional dredging will be removed from within the model. Retain the damage repair requirements to the jetty section and track as a breach in order to distinguish from a repair volume related to general damage. Tracking the damage as a breach will enable the model to indicate at what point a breach is probable and it will help inform maintenance strategy and repair cost.

j. Task 10: Utilize Improved Model. Assist USACE Product Development Team with the evaluation of alternatives utilizing the improved SRB model. The alternatives should remain the same or similar to the previously used alternatives, however, the base condition will require to be altered to represent the changed site conditions that will occur as a result of the North Jetty Major Maintenance Report (NJ MMR) that was written after the MCR Major Rehabilitation Report and has been submitted for the FY 2012 budget. Provide an economist that will assist the USACE PDT with plan formulation, evaluation of the alternatives and performing the economic analysis.

k. Task 11: Incorporate New Data and Streamline Report. Assist USACE Project Development team with the incorporation of results from the new model runs into the existing Major Rehabilitation Report. During and prior to the process of incorporating the new model data the AE team will review the report and with PDT concurrence make modifications that increase the readability of the report. The goal of the modifications shall be to retain the existing information while shaping the report into a more concise document.

4. MANDATORY SUBMITTALS TO BE PROVIDED. Under this modification, the Contractor shall provide the following:

> **a. Submittal 1 Model code and Documentation** user's manual, revised A1 and A2 appendices reflecting model code changes and validation and verification files.
>
> **b. Submittal 2 Revised Major Rehab Report.** Provide the text and technical writing services to revise the existing Major Rehabilitation report as follows; describe the basis of design and engineering criteria used for plan formulation incorporating modifications to the alternatives, justification for head-capping and spur groin locations and selection of alternative.

5. SCHEDULE. All services required under this task order modification shall be completed no later than 20 January 2012. It is anticipated that the Notice to Proceed (NTP) for this modification will be issued by Oct 14, 2011.

6. ONLY WHEN AUTHORIZED (OWA) SERVICES. The following OWA tasks will be negotiated and funded at time of award. The Contractor shall not perform any OWA services without specific written direction from the Contracting Officer's Representative.

a. <u>Additional Meetings</u>. Establish two (2) units of additional OWA meetings. Each unit shall be for three (3) people for two (2) days. Costs shall include travel and per-diem to Portland, Oregon.

Planning, Programs and Project
Management Division

Bernard Moseby
National Deep Draft Navigation Planning Center of Expertise
Mobile District, USACE
PO Box 2288
Mobile, AL 36628-0001

Dear Mr. Moseby:

The purpose of this letter is to inform you that Portland District is submitting to the National Deep Draft Navigation Planning Center of Expertise (DDNPCX) a reliability model of the jetty system at the Mouth of the Columbia River (MCR). Portland District requests that the Center conduct the approval process of this model per EC1105-2-407.

This computer model is to be used in the Major Rehabilitation Study of the jetties at the Mouth of the Columbia River (MCR). The model is written in Matlab and is actually three separate models, one for each of the jetties there; North Jetty, South Jetty, and Jetty "A". The model and supporting files have been placed on the USACE public FTP location: ftp://ftp.usace.army.mil/pub/nwp/MCR_SRB_review/

These files will be available for ten days on the FTP site. The files will need to be re-posted if you do not download them within this timeframe.

NWP Points of Contact are as follows:

Rod Moritz 503-808-4864, Technical expert;
Jason Magalen, 503-808-4832, Technical assistant;
Tom Hackett, 503-808-4769, Planning POC;
Brian Shenk, 503-808-4221, Economics POC.

Because of the size and complexity of the model, we are recommending that the model reviewer or reviewers communicate periodically with key NWP personnel during the review process. We would like to work with you once the review team is developed to establish an appropriate way to check in on comments, and maintain the review schedule. If you would like, we are available to conduct a kick off meeting with the review team to introduce and explain the model.

Please provide the reviewers names, and the review and approval schedule. Tom Hackett of my staff is managing the review process for the District and he will be in contact with you during the review period. You may contact him at (503) 808-4769 or email at thomas.w.hackett@usace.army.mil.

Sincerely,

for Christine McBurden

CENAE-EP-HG 24 August 2010

MEMORANDUM FOR: Mr. Bernard E. Moseby, CESAM-PD-FE, Chief, Economic Analysis and Deputy Director, Deep Draft Navigation Planning Center of Expertise

SUBJECT: Review and Certification Letter for the Mouth of the Columbia River (MCR) Stochastic Reliability Based (SRB) Lifecycle Model for the MCR Major Rehabilitation Report

The following is the background information on the review process for the certification of the MCR SRB Lifecycle Model:

1. In October 2009, a request was made by the NWP PM to the ATR team leader to assist in obtaining model certification of the Mouth of the Columbia (MCR) Stochastic Reliability Based (SRB) model. This process was conducted using current USACE planning guidance and coordinated through the Deep Draft Navigation PCX to request from USACE Headquarters an "approved for use" status of the MCR SRB model.

2. A technical review of the MCR SRB model was initiated in November 2009 and has continued to date utilizing both part of the ATR team (Mr. Robert C. Patev, Team Leader and Mr. Wally Brassfield, ATR cost team member) and Mr. John Winkelman, a Coastal Regional Technical Specialist (RTS), from North Atlantic Division (NAD). Since the MCR SRB model was developed using the MATLAB language/software, Mr. Winkelman was an important part of this team due to his knowledge of the software, his technical position as a coastal engineer/planner Regional Technical Specialist with the HSDR PCX, and his past work experience in SPD on West Coast coastal navigation projects.

3. The review was begun in November 2009 by Mr. Patev and Mr. Winkelman and included a visit to CENAE by Mr. Hans Moritz, who is the developer of the MCR SRB model. The meeting lasted approximately two days and included a detailed presentation of the model code, model development assumptions, variable and model input descriptions, a discussion of the model output, and a lengthy discussion of model philosophy. Questions or comments generated prior to and during the meeting were documented and addressed as part of the Dr. Checks review process. Twenty three comments were generated and submitted into Dr. Checks in January 2010. Questions and comments were related to model coding, model variables and model constant value selection, model assumptions, and limited coastal engineering issues. Each issue and question was answered and/or addressed satisfactorily.

4. Following this meeting and installation of the MCR SRB MATLAB code at NAE, a number of variables and their ranges were defined to investigate model performance, sensitivity, and stability of the code. This was performed in terms of engineering reliability aspects of the program only. During this phase of the review, Mr. Moritz provided the review team with a list of key variables and constants within the code for validation. Many of these variables were discussed further during a number of

email/phone exchanges during this phase. After these communications and detailed examination of the code, the values selected in the model for engineering parameters were determined to be reasonable and based upon a sound engineering decision process. When these values were changed in the model, noticeable changes to the model output were recognized, but the model did not produce any unreasonable results in terms of engineering reliability.

5. The values for costs included in the MCR SRB model were reviewed and modified by Mr. Brassfield in July 2010. However, the validation of the methods and mathematical calculation for the estimation of the economic consequences produced by the model has not been reviewed by any team member since this was outside of their areas of expertise.

The following limitations, review assumptions and technical recommendations were drawn by the review team during their review:

1. With a model of this size and complexity it is difficult to determine if all of the code is error proof or if the model is providing the exact correct answer. However, based on the review, as described, the model, from a coastal analysis/performance stand point does appear to be reasonable and is a reasonable tool for determining the future, relative performance of various maintenance schemes for the MCR jetties discussed in the MRR. As with any model of this complexity, and for a system of this complexity, the precise numbers and resulting values are likely not absolutely correct but instead are reasonable and relatively correct between alternatives.

2. This model and code has only been reviewed as to what was included in the code installed at NAE in 2009. This review was limited only to the aspects of the engineering reliability and not the actual consequence determination in the program. The cost inputs have been reviewed by the ATR cost team member but the application of the economics to the outputs has not been validated as part of this review. In addition, any additional changes or modifications of the code should be reviewed by the ATR team to determine the validation of those modifications to the code and the replication of the results with previous versions of the code.

3. The MCR SRB model was developed to perform an integrated analysis of both engineering reliability and consequence assessment. Typically, major rehabilitation models are developed separately into stand alone models for engineering reliability and economic consequences. If the schedule permits, I would strongly recommend that the SRB process and results be validated with a simpler model using hazard functions from the SRB reliability curves and the development of consequences using a traditional economic simulation model.

4. During the Independent External Peer Review (IEPR), it is important to provide the additional documentation and explanations discussed in my previous comments. Also, the face to face meeting for explaining the model is essential due to the complexity of the model. This is a model that is trying to meet a difficult USACE planning objective that covers an immensely complicated coastal engineering project and forecasts an uncertain

future. It should also be made clear what the purpose of the model is, and that this is a project specific model that has been developed, honed, and calibrated for this specific project area. The numerous factors and variables, etc. within this model, to a great extent, are project specific and are not to be used in a generalized model for other USACE projects.

5. Based on the information presented above, I recommend that the MCR SRB lifecycle model be certified as is and a request be sent to USACE Headquarters as "approved for use" for the MCR Major Rehabilitation Report only.

If there are any questions regarding this memorandum, please do not hesitate to contact me at your earliest convenience.

Robert C. Patev
ATR Team Leader
NAD Navigation RTS

CESAM-PD-FE

18 January 2011

MEMORANDUM FOR COMMANDER, South Atlantic Division, ATTN: WILBERT V. PAYNES, (CESAD-PDS-P)

SUBJECT: Model Certification – Approval for Use, Columbia River at the Mouth, Oregon and Washington, Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Stochastic Reliability-Based (SRB) Model

1. References:

a. EC 1165-2-209, Civil Works Review Policy, 31 January 2010

b. EC 1105-2-412, "Assuring Quality of Planning Models" dated 20 July 2009,

c. EC 1105-2-407, "Planning Models Improvement Program: Model Certification" dated 31 May 2005.

d. Memorandum, CECW-CP, 30 March 2007, Subject: Peer Review Process

e. Supplemental information for the "Peer Review Process" Memo, dated March 2007

2. In accordance with EC 1165-2-209, "Civil Works Review Policy" Model Certification – Approval for Use, the Major rehabilitation of the Jetty System at the Mouth of the Columbia River, Stochastic Reliability-Based (SRB) Model, has been coordinated with and executed through the Deep Draft Navigation Planning Center of Expertise (DDN-PCX).

3. The review was a Level I review - for highly complex models used in decision-making where there could be a high risk of making an incorrect investment decision.

4. The review was performed by Robert C. Patev, CENAE-EP-WG, Team Leader and John Winkelman, CENAE-EP-WM, New England District, Corps of Engineers. The Model Assessment Criteria documentation that supports a recommendation of 'Approval for Use' for the SRB Model is enclosed. The Deep Draft Center is requesting coordination of the enclosed certification package through the Planning CoP Leader for processing, review and recommendation.

4. The Deep Draft Navigation Planning Center of Expertise (DDN-PCX) point of contact is Bernard Moseby, CESAM-PD-FE, (251)-694-3884.

BERNARD E. MOSEBY
Technical Director, DDN-PCX

Model Approval Plan
(Supplemental)

Stochastic Reliability Based
MATLAB model
MCR jetties

Mouth of the Columbia River
Major Rehabilitation Report

CENWP

1. Purpose

The purpose of this Model Approval Plan is to outline the review process and requirements necessary to assure the quality of the Stochastic Reliability Based MATLAB model for the MCR jetties (SRB), as submitted from the CENWP to the DDPCX in support of the Approval for Single Use of the model in the Mouth of the Columbia River, Major Rehabilitation Report (MCR MRR). This review plan is based on the requirements contained in *EC 1105-2-412 Assuring Quality of Planning Models* and the *Standard Operating Procedures for the Processing of Planning Model Certification/Approval Actions,* which complements Engineering Circular 1105-2-412 (EC) and provides a guideline for implementation of the EC. The MCR SRB model has been in development since 2005, significantly pre-dating the EC, therefore the model is in the latter stages of the review/approval process. This plan is intended to capture what has already been done and describe how the PDT intends to complete the model approval process.

2. Reference and Guidance

2.1. Engineering Circular 1105-2-412, Assuring Quality of Planning Models, 31 March 2011.
2.2. Budget Engineer Circular (EC) 11-2-199, dated 31 March 10
2.3. Standard Operating Procedures for the Processing of Planning Model Certification/Approval Actions dated 16 November 2010

3. Background

Stochastic Reliability Based (SRB) model developed for the Mouth of the Columbia River (MCR) evaluates the expected reliability of different alternative cross-sections of the three existing jetties. The wave climate and damage function currently used in the model are specific to the MCR. EC 1105-2-412, Assuring Quality of Planning Models makes a distinction between model certification and model approval based upon the origin of the model and the extent of the model's intended use; Section 5. c stipulates that models that have been developed by the corps (or outside entities) and are viewed by the vertical team as single-use or study specific models require model approval. Models which will be used over a wider range of conditions and locations require certification. At this time the PDT recommends that the MCR SRB model be considered a Regional/Local Model as defined EC 1105-2-412 section 5. a. (2) and that it be reviewed for approval, not certification due to it being specific to the MCR jetties in its current form.

The MCR SRB model has been developed over several years and has been subjected to an Agency Technical Review (ATR). After incorporating comments the model was reviewed during the Independent Engineering Peer Review (IEPR) of the MCR Major Rehab Study (Attachment 1). The MCR SRB model has not received approval for use from HQUSACE and two IEPR comments that were specific to the model have not been resolved. In order to address the IEPR team's unresolved comments CENWP solicited the assistance of the firm Moffat and Nichol via a two phase task order to review the model, associated documentation and engineering regulations and identify specific changes that need to be made in the model code and assist CENWP in making those changes. Phase I of the task order produced a letter report (Attachment 2) that evaluates the functionality of the MCR SRB model and identified nine specific improvements to the model code that address the outstanding concerns regarding the model. All nine of the recommendations were adopted by the PDT and two additional tasks related to including the updated model and the results into the MCR Major Rehabilitation Report (MRR) were incorporated into the task order modification for phase II (Attachment 3).

3.1 Previous Reviews

A review plan for the MCR Major Rehabilitation Report was last revised in September 2010 and submitted to the DDPCX for consideration. The review plan described the series of reviews for the different elements required for the report.
This Review Plan (RP) outlined the reviews as required by EC 1105-2-410. The RP supplements the Project Management Plan (PMP) and identified three levels of peer review: District Quality Control (DQC), Agency Technical Review (ATR), and Independent External Peer Review (IEPR) based on the scale, impacts, and cost of this project.
All decision documents and their supporting analyses have undergone DQC, ATR and IEPR, to "ensure the quality and credibility of the government's scientific information", in accordance with EC 1105-2-410 and the quality management procedures of the responsible command. The Circular addresses review of the decision document as it pertains to both approaches and planning coordination with the appropriate Center. The Circular also requires that DrChecks be used to document all ATR and IEPR comments, responses, and associated resolutions accomplished. These requirements have been met for the multiple components of the MCR MRR and the comments and responses are attached to this model review plan for consideration.

The types of technical reviews that were conducted are provided below.

3.1 a District Quality Control (DQC).

DQC is the review of basic science and engineering work products focused on fulfilling the project quality requirements defined in the Program Management Plan (PMP). It was managed in the home district and may be conducted by staff in the home district as long as they are not doing the work involved in the study, including contracted work that is being reviewed. Basic quality control tools include a Quality Management Plan providing for seamless review, quality checks and reviews, supervisory reviews, Project Delivery Team (PDT) reviews, etc. Additionally, the PDT is responsible for a complete reading of the report to assure the overall integrity of the report, technical appendices and the recommendations before approval by the District Commander. It is expected that the MSC/District quality management plans address the conduct and documentation of this fundamental level of review. DQC is not covered by this Review Plan. The MCR MRR was assigned a separate DQC review team to present an unbiased opinion of the technical merits of the report. The DQC team was led by the Deputy Chief of Engineering and Construction and the review resulted in XXXX comments and responses which had a dramatic improvement on the report.

3.1 b Agency Technical Review (ATR).

ATR (which replaces the level of review formerly known as Independent Technical Review) was an in-depth review, managed within USACE, and conducted by a qualified team outside of the home district that was not involved in the day-to-day production of a project/product. The purpose of this review was to ensure the proper application of clearly established criteria, regulations, laws, codes, principles and professional practices. The ATR team reviewed the various work products and assures that all the parts fit together in a coherent whole. The ATR team was comprised of senior USACE personnel, the ATR team roster is attached. To assure independence, the leader of the ATR team was chosen from outside the home MSC.

3.1 c Independent External Peer Review (IEPR).

This is the most independent level of review, and is applied in cases that meet certain criteria where the risk and magnitude of the proposed project are such that a critical examination by a qualified team outside of USACE is warranted. The criteria for application of IEPR include, but are not limited to (1) the total project cost exceeds $45 million; (2) there is a significant threat to human life; (3) it is requested by a State Governor of an affected state; (4) it is requested by the head of a Federal or state agency charged with reviewing the project if he/she determines the project is likely to have a significant adverse impact on resources under the jurisdiction of his/her agency after implementation of proposed mitigation (the Chief has the discretion to add IEPR under this circumstance); (5) there is significant public dispute regarding the size, nature, effects of the project; (6) there is significant public dispute regarding the economic or environmental cost or benefit of the project; (7) cases where information is based on novel methods, presents complex challenges for interpretation, contains precedent-setting methods or models, or presents conclusions that are likely to change prevailing practices; or (8) any other circumstance where the Chief of Engineers determines IEPR is warranted. IEPR may be appropriate for feasibility studies; reevaluation studies; reports or project studies requiring a Chiefs Report, authorization by Congress, or an EIS; and large programmatic efforts and their component projects. It was determined that MCR MRR warranted an IEPR. The IEPR was managed by Bechtel, an eligible outside organization. The scope of review addressed all the underlying planning, engineering, including safety assurance, economics, and environmental analyses performed, not just one aspect of the project. A review of the attached charge questions given to the IEPR team indicates that the MATLAB model received a comprehensive review by qualified programmers and ocean engineers. The IEPR charge questions and comments and responses are attached. Three of the IEPR comments resulted in comments and responses dialogues where the IEPR team and the PDT were unable to reach concurrence.

3.2 Post IEPR Activity

In an effort to resolve the non-concur items identified in the IEPR, CENWP engaged the services of Moffatt & Nichol and together with the PDT has outlined a path forward to resolve the open IEPR comments by improving the model code, allowing for the transparency, compliance with current technology and corps policy, documentation, practicality with data inputs and outputs and clearly identifying the use and limitations of the model consistent with EC 1105-2-412. Following is a list of the steps contained in EC 1105-2-412 and the actions that the PDT has either taken or propose to take to satisfy those steps:

Step 1: Proponent Identifies model to be used for a national, regional or local application and PCX determines the need for certification or approval.

Response: The proponent is CENWP, and we have identified the model as Regional/Local model developed by USACE with assistance from a non-corps entity (Moffat & Nichol) as a study specific model, therefore the PDT believes model approval not certification is required.

Step 2: Proponent submits model and documentation to the appropriate PCX.

Response: PDT has forwarded the model code, ATR and IEPR comments to the DDPCX. DDPCX determined that the model was not approvable via memo indicating that the PDT should resolve outstanding IEPR comments prior to approval. PDT has engaged an expert modeling team from a qualified AE firm. Updated model and documentation will be sent to DDPCX for review and approval.

Step 3: PCX determines appropriate level of review utilizing the criteria outlined in EC. PCX has final approval on level of review.

Response: The MCR SRB model development predates the EC, so a formal review level was never assigned. It is assumed by the PDT that the model will require a level 1 or level 2 review.

Step 4: PCX establishes a review team, team leader and defines the anticipated charge scope of review. The review charge and scope should guide the product reviewers and direct them to key issues, assumptions, routines and aspects for review. A team selected from the roster of qualified reviewers maintained by the appropriate PCX, including external and internal reviewers, will conduct Level 1 and Level 2 reviews. Level 3 and Level 4 reviews may be conducted by Corps internal experts, but the review team, as deemed appropriate by the PCX, could include external individuals as well. Protocol and procedures for the model review process will be specified in the PCX standard operating procedures (SOP) and will reflect prevailing industry practices.

Response: The MCR PDT worked with the PCX (if it wasn't DDPCX then list who please) to conduct the model ATR and the overall MCR Major Rehabilitation Report (MCR MRR) IEPR, which included an extensive number of PCX recommended questions regarding the model, modeling process and interpretation of the results into the MCR MRR. The results of both reviews have been received by the DDPCX. Outstanding comments from the IEPR are being resolved as previously described and it is the belief of the PDT that the resolution of the comments shall conclude the review process and provide the DDPCX with the information and documentation required to render approval.

Step 5: The PCX develops a certification plan to include to include the information from steps 1-4, defining the scope of the review. The certification plan (and accompanying model documentation materials) is submitted to CECW-P for approval. Written approval from CECW-P must be received by the PCX prior to proceeding with the certification review.

Response: The MCR PDT has been pursuing an overall Major Rehabilitation Report approval process, of which the model approval is a component. The MCR PDT engaged the vertical team as well as the relevant PCX(s) to develop a review and approval plan early in the development stages of the project. The review plan included DQC, ATR (model specific and report) prior to conducting an IEPR. The PDT would like the DDPCX to give consideration to the previously conducted reviews, the changes generated from the reviews and the future actions described in this plan. If there are additional steps required that has not been completed or proposed in this plan please identify and the PDT will include them prior to submission for approval.

Step 6: Once the PCX has received approval to proceed, the PCX will hold an initial meeting to begin the certification process to assure that all participants understand the nature of the effort, as well as to discuss any particular technical or administrative issues that will be important in the review. The meeting (which can be held by teleconference) will include representatives of the PCX, the model proponent and the review team. CECW-P will be notified of the meeting and invited to attend.

Response: The goal of the project's proponent, CENWP, is to complete the revised MCR MRR in time for submission in the FY 14 budget request. In order to accomplish this goal the PDT requests that the PCX forward the review plan to CECW-P as soon as possible and schedule the teleconference to assure that the actions proposed by the PDT are consistent with the requirements for model approval.

Step 7: In fulfilling it's role, the review team will provide to the PCX a consolidated documentation of review comments and recommendations. The review should adhere to the review charge and scope provided by the PCX. The PCX will strive for consensus, but one or more reviewers may not concur with the views of the majority. Matters of disagreement should be addressed forthrightly in the report. As a final recourse, a reviewer may choose to prepare a brief dissent describing the issues of contention and arguments in support of the minority view. To encourage reviewers to express their views freely, the review comments are treated as panel responses and are given to proponents with identifiers removed.

Response: This process was conducted during the rigorous IEPR conducted from November 2010 through March 2011. The review team was comprised of external experts and the review was conducted according to the process described in EC 1165-2-209 and supplemental implementation guidance. The charge questions were developed with the assistance of the PCX and are attached to this plan as appendix D. A review of the charge questions will demonstrate that the IEPR team was directed to review the model carefully and render a professional opinion on the quality and to make recommendations on how to overcome deficiencies noted. The PDT is currently pursuing their recommendations.

Step 8: Review comments are provided to the PCX within 90 days after submittal of the model for review to the review team. (Ninety days is the estimated maximum time for review of models in level 1. For models in other categories, the review time will be adjusted accordingly, and is expected to be less than 90 days.) The PCX then assesses whether the review team fulfilled the charge and scope provided. When the PCX determines that the review charge and scope have been met, the comments are provided to the proponent for review and response, and a checkpoint meeting is scheduled to discuss the review comments and issues for response. The checkpoint meeting will be held with the same parties as the initial meeting in Step 6, above.

Response: The IEPR process is in the final stage, resolution of outstanding comments. The charge questions provided and agreed upon by PCX and PDT were the basis of the IEPR.

Step 9: Feedback from the proponent, within 30 days after receipt of the comments, is transferred through the PCX back to the review team until all comments are either resolved or all parties reach an agreement on outstanding issues. The PCX will strive to resolve all comments, but not all comments may be resolved. CECW-P in consultation with the HQ Model Certification Panel, the proponent and the PCX will have the final decision on comment resolution and product certification/approval. The final decision on model certification/approval should be made within 90 days after initial submittal of review comments to the proponent. (In cases where substantial revisions are made to the model, this time period may be longer).

Response: The project is currently at this stage. The outstanding comments are being resolved by streamlining the model, increasing transparency and reconfiguring the model code into modules in order to track interim results. The SRB model will be reconfigured in order to provide the ability to utilize an input files that generate discrete output results. This process will increase the ability of the PDT to evaluate alternatives quickly and efficiently.

Step 10: The PCX will furnish Headquarters Planning Community of Practice Leader the documentation of the review, model documentation, and a recommendation for or against certification/approval. CECW-P, in consultation with the Model Certification HQ Panel, will make the determination to certify/approve or not certify/approve the model. Upon certification/approval, CECW-P will issue a certification/approval memorandum and (for certified models) instruct the PCX to add the model to the National toolbox of certified models.

Response: The documentation has been submitted. Additional documentation describing the changes made and actions taken, along with the model code will be re-submitted as soon as it is available.

4. Documentation Provided by Proponent

Notification to DDPCX from CENWP-P	Attachment 4
MCR SRB Model Certification Memo	Attachment 5
Deep Draft PCX Approval for Use	Attachment 6

4.1. Model Technical Documentation

- **Calibration Results Documentation**

Moffat and Nichol, working with the PDT is currently reviewing the model calibration and will produce a calibration report with the PDT. Document will be available when received and approved. (see task 3 MCR MN SOW MOD2 attachment 3).

4.2. Model User Documentation

- The PDT and Moffat and Nichol are currently reviewing the model operations and establishing code that will allow the model to accept and produce input/output files. Upon completion of this task the Model User Guide will be updated and forwarded.

4.3. Model Support Literature

-

4.4. Model QA/QC Documentation/Activities

- Notification to DDPCX from CENWP-P Attachment 4
- MCR SRB Model Certification Memo Attachment 5
- Deep Draft PCX Approval for Use Attachment 6

5. Type/Scope of Review

Per EC-1105-2-412, 31 March 2011, the PCX recommended an Extensive Review. The model is currently undergoing an extensive review and the PDT recommends continuing, but not re-initiating, this process

The following language defines the scope of the review and will be provided to the model reviewers:

5.1. Preliminary charge for reviewers of the MCR Stochastic Reliability Based Model

The initial charge given to the ATR review and IEPR review team is shown below. In addition to the underlying theory, conceptualization, and computational aspects of the model, reviewers are asked to comment on aspects of the model that potentially affect its usability and reliability as a potential producer of information to be used to influence planning decisions.

While the specific review questions included below were intended to prompt the reviewer for information specific to the efforts to Approve for Single Use, the reviewers were encouraged to offer comments believed relevant and appropriate to any elements of the technical quality and usability of the model, Major Rehab Report and appendices as documented in the provided review materials. Accordingly, please provide responses to the sought scientific and technical topics listed below and perform a broad review of the focusing on your areas of expertise, experience, and technical knowledge. Listed below are the model review charge questions.

IEPR Charge Questions relevant to the Model Provided by PDT

1. Is the purpose of the model clearly defined?

2. Is the model diagram easily understood.

3. Does the model follow a logical programming path.

4. Is the model free from programming errors that would alter the model results significantly enough to skew the plan selection?

5. Does the model adequately capture and evaluate all of the relevant variables.

6. Can the model described achieve the stated purpose?

7. Does the model accurately describe (model) repair activities and sequences? Is it modeling the repair activities similarly to how the repairs will be sequenced and performed.

Technical Quality

8. Comment on the overall technical quality of the model.

9. Is the model based on well-established contemporary theory?
    a. Is the available science applied correctly?
    b. Are the models empirically supported?

10. Is the model a realistic representation of the actual system?

11. Are the analytical requirements of the model properly identified?

12. Does the model address and properly incorporate the analytical requirements?

13. Are the assumptions clearly identified, valid, and do they support the analytical requirements?

14. Are the formulas used in the model mathematically correct and are the model computations appropriate and done correctly?

15. Comment on the ability of the model to address risk and uncertainty.

16. Comment on the ability of the modes to calculate benefits for total project life.

17. Does the model adequately assess the full range of costs associated with the three jetties?

18. Will the model be useful in capturing and quantifying the full extent of benefits expected to be obtained from anticipated repairs?

System Quality

19. Has the model been sufficiently tested and validated, or do critical errors still exist?

Usability

20. Comment on the models' usability.

21. Comment on the availability of the data required by the model.

22. How easily are model results understood?

23. Comment on how useful model results are for supporting project objectives.

24. Is user documentation available, user friendly, and complete?

25. Is the model transparent and does it allow for easy verification of calculations and outputs?

OTHER GENERAL QUESTIONS

26. Can the model be adapted to other geographic regions?
    a. If so, how much can the model be modified before they need to be reviewed again?

27. Is it clear where the model's geographic boundaries fall?

28. Is the approach to the development and use of the model described clearly enough to allow the approach to be repeated and obtain the same or similar results?
    a. If not, why?
    b. If not, what needs to be done to make the approach repeatable?

29. Comment on the ability of the model to calculate benefits for total project life.

30. Is the application of the model defensible?

31. Comment on whether there are any resolution issues with the model (i.e., size of the area that can effectively be evaluated).
    a. At what scale (e.g. acres, hundreds of acres) can the models be effectively applied?

32. Comment on whether all of the most important variables are included in the model.
    a. Are variables that are both stressors and drivers included in the model?
    b. Should additional variables be included?
    c. Are some of the variables more sensitive than others?

33. To what extent is best professional judgment used in the model?

34. To what extent is the model developed specifically for the MCR Jetties?

35. Are error checks built into the model?

36. Are USACE policies and procedures related to the model clearly identified?

37. Does the model properly incorporate USACE policies and accepted procedures?

38. Is sea level change addressed by the model?
    a. If yes, is it internal to the model or does it need to be addressed externally?

5.2 Follow-On review charge.

The reviewers will not be charged with initiating a new review of the product in its entirety. The reviewers are charged with reviewing the IEPR comments and responses, and the PDT's subsequent actions, edits and changes in order to confirm that the PDT has adequately addressed the IEPR panel's questions. Follow-up questions made by the reviewers will also be addressed by the PDT until the reviewers, and the PDC, are satisfied that all outstanding issues have been resolved.

6. DNN-PCX Summary.

The DDN-PCX will provide a summary of review findings, which will include a summary of comments, and a strategy for implementing any necessary actions to remedy any additional or remaining deficiencies. The DDN-PCX will close-out the review when it determines identified issues have been resolved to its satisfaction.

FINAL
INDEPENDENT EXTERNAL PEER REVIEW REPORT
for the

Columbia River at the Mouth, Oregon and Washington
Major Rehabilitation Evaluation Report

EXECUTIVE SUMMARY

Project Background and Purpose

The Mouth of the Columbia River (MCR) navigation project is located at the confluence of the Columbia River with the Pacific Ocean on the border between Washington and Oregon. Navigation is maintained by three primary navigation structures, North Jetty, South Jetty, and Jetty A. The North Jetty and Jetty A are located in Pacific County, Washington, near Ilwaco and Long Beach on the Long Beach Peninsula. The North Jetty was completed in 1917. Jetty A, positioned on the south side of the North Jetty, was constructed in 1939 to a length of 1.1 miles. Jetty A was constructed to direct river and tidal currents away from the North Jetty foundation. The South Jetty is located in Clatsop County, Oregon near Warrenton/Hammond and Astoria. The initial 4.5-mile section of the South Jetty was completed in 1895, with a 2.4-mile extension completed in 1913. Jetty construction realigned the ocean entrance to the Columbia River, established a consistent navigation channel that was 40 feet below MLLW across the bar, and significantly improved navigation through the MCR. Improvements made from 1930 to 1942 (including addition of Jetty A and Sand Island pile dikes) produced the present entrance configuration. Each year, ocean-going vessels on the Columbia River carry about 40 million tons of cargo with an estimated value of $17 billion on an annual basis. More than 12,000 commercial vessels and 100,000 recreational/charter vessels navigate through the MCR annually.

Prior to improvement in 1885, the tidal channels through the MCR shifted north and south between Fort Stevens and Cape Disappointment, a distance of about 5.5 miles. The controlling depth of dominant channel through the ebb tidal delta varied between 18 to 25 feet deep below MLLW. The ebb and flood tidal deltas at MCR entrance were distributed over a large area immediately seaward and upstream of the river mouth. Ships often had difficulty traversing the Columbia River bar, the area in which the flow of the estuary rushes headlong into towering ocean waves. On many occasions, outbound ships had to wait a month or more until bar conditions were favorable for crossing. To make navigating through the MCR even worse, sailing ships had to approach either of the two natural channels abeam to the wind and waves. The natural channels often shifted widely within the course of several tidal cycles. At best, crossing the bar was dangerous. At worst, it was not possible. Offshore of the MCR lies the vast expanse of the northeast Pacific Ocean. Inshore of the MCR lies the Columbia River and estuary, the coastal outlet for a drainage basin of 250,000 square miles.

Despite intermittent repair and partial rehabilitation efforts, all of the MCR jetties are currently in an unacceptably deteriorated condition. This project was undertaken to address problems related to the structural stability of the MCR jetty system in order to extend the functional life of the jetties and maintain deep-draft navigation.

Independent External Peer Review Process

USACE is conducting an Independent External Peer Review (IEPR) of the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report (hereinafter Mouth of Columbia River IEPR). Battelle, as a 501(c)(3) non-profit science and technology organization with experience in establishing and administering peer review panels for USACE, was engaged to coordinate the IEPR of the Mouth of Columbia River Major Rehabilitation Evaluation Report. Independent, objective peer review is regarded as a critical element in ensuring the reliability of scientific analyses. The IEPR was external to the agency and conducted following USACE and Office of Management and Budget (OMB) guidance described in USACE (2010), USACE (2007), and OMB (2004). This final report describes the IEPR process, describes the panel members and their selection, and summarizes the Final Panel Comments of the IEPR Panel (the Panel).

Five panel members were selected for the IEPR from more than 28 identified candidates. Based on the technical content of the Mouth of Columbia River Major Rehabilitation Evaluation Report and the overall scope of the project, the final panel members were selected for their technical expertise in the following key areas: design and construction engineering (coastal engineering), plan formulation, biology NEPA, hydrology and hydraulics engineering/coastal engineering, geomorphology, and economics. USACE was given the list of candidate panel members, but Battelle made the final selection of the Panel.

The Panel received electronic versions of the Mouth of Columbia River IEPR documents, totaling more than 1,000 pages, along with a charge that solicited comments on specific sections of the documents to be reviewed. The charge was prepared by USACE according to guidance provided in USACE (2010) and OMB (2004). Charge questions were provided by USACE and included in the draft and final Work Plans.

The USACE Project Delivery Team briefed the Panel and Battelle during a kick-off meeting held via teleconference prior to the start of the review. In addition to this initial teleconference, a second teleconference with USACE, the Panel, and Battelle was conducted halfway through the review period to provide the Panel an opportunity to ask questions of USACE and clarify uncertainties. The Panel produced more than 500 individual comments in response to the 78 charge questions.

IEPR panel members reviewed the Mouth of Columbia River IEPR documents individually. The panel members then met via teleconference with Battelle to review key technical comments, discuss charge questions for which there were conflicting responses, and reach agreement on the Final Panel Comments to be provided to USACE. Each Final Panel Comment was documented using a four-part format consisting of: (1) a comment statement; (2) the basis for the comment; (3) the significance of the comment (high, medium, or low); and (4) recommendations on how to resolve the comment. Overall, 25 Final Panel Comments were developed. Of these, 8 were identified as having high significance, 14 had medium significance, and 3 had low significance.

Results of the Independent External Peer Review

The panel members agreed among one another on their "assessment of the adequacy and acceptability of the economic, engineering, and environmental methods, models, and analyses used" (USACE, 2010; p. D-4) in the Mouth of Columbia River IEPR document. Of primary significance, and as discussed in several of the Final Panel Comments, the Panel has serious concern with the SRB model and the potentially over-emphasized role it played in the evaluation of alternatives, engineering design, and economic analyses. Table ES-1 lists the Final Panel Comments statements by level of significance. The full text of the Final Panel Comments is presented in Appendix A of this report. The following statements summarize the Panel's findings.

Plan Formulation Rationale: From a planning perspective, the Major Rehabilitation Evaluation Report is well done and in compliance with all of the typical formulation steps; however, it was never clearly explained that the scope of work was limited to the repair and rehabilitation within the present configuration, nor why it was limited in this manner. Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected. The Panel agreed that the SRB model is not a substitute for conventional engineering and economic analyses and should not be a stand-alone analysis for selecting a recommended plan.

Economics: The Panel identified three major issues in the economic analysis: (1) inconsistencies in the Major Rehabilitation Evaluation Report and economic spreadsheet models; (2) the assumption that navigation would not be impacted; and (3) the formulation of the base condition. Inconsistencies in the report and economic spreadsheet models pertaining to the calculation of NPVs and AACs prevented the Panel from validating the economic analysis. Based on the assumption that navigation will not be impacted, a least cost analysis was used in lieu of a transportation cost savings analysis to calculate NED benefits. Conflicting assumptions concerning the ability to maintain navigation invalidate the logic behind calculating NED benefits using a least cost analysis. As the project is currently formulated, the base condition maintenance strategy for the MCR jetties conforms most closely with the fix-as-fails strategy, while the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits. Each of these issues could impact the selection of the NED plan, which was selected as the recommended plan.

Engineering: There are serious technical difficulties with the Major Rehabilitation Evaluation Report and analyses. The report lacks a set of design criteria, including project life, standards of performance to be met, and environmental conditions with return period events. All are part of conventional coastal engineering design practice. The SRB model cannot be verified and does not include important processes. Major questions remain that have not been adequately investigated for this level of study, including subsurface geotechnical properties, feasibility of proposed barge offloading/material re-handling facilities, and the long term stability of the jetty foundations assuming continued erosion and loss of nearshore sediment. The report indicates that large volumes of sediment will move into the navigation channel after a breach event. However, the data and analysis do not support this conclusion. Additionally, is no clear discussion of the role of maintenance or emergency dredging, especially under extreme winter conditions. Detailed construction cost estimates also need to be provided in order for the cost analysis to be complete and verifiable. Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition.

Environmental: There is no discussion in the main report of sea level rise and potential wave height increases and its impact on this project over the 50+ year project timeline, given that the regional wave climate has been documented as more severe in the last 10 years. This has potential impacts to the project and in designing a project with lower long-term maintenance costs. Potential environmental impacts on sensitive species, upland habitats, and water quality as well as potential impacts to recreational use during project construction are not comprehensive nor adequately described in the mitigation plan. Finally, the alternatives are limited to armoring the existing configuration of the jetties and may not satisfy NEPA directive for alternative analysis.

Table ES-1. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel

Significance – High	
1	The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.
2	The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.
3	The underlying assumption that navigational impacts will not occur is not substantiated.
4	The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
5	The base condition, as formulated, does not represent the current O&M practice.
6	The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
7	The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.
8	The models and analyses of jetty failure do not include all significant processes.
Significance – Medium	
9	The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
10	A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
11	Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.

Table ES–1. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel, continued

Significance – Medium	
12	Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.
13	Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.
14	Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.
15	There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.
16	The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.
17	The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
18	The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.
19	Risk thresholds for selected alternatives are not clearly defined.
20	It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
21	The model output parameters and wave height components are not clearly explained and supported.
22	The culvert installation details, as well as potential impacts, need further clarification.
Significance – Low	
23	The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
24	Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.
25	Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.

1. INTRODUCTION

The Mouth of the Columbia River (MCR) navigation project is located at the confluence of the Columbia River with the Pacific Ocean, on the border between Washington and Oregon. Navigation is enabled by three primary navigation structures, North Jetty, South Jetty, and Jetty A, plus maintenance dredging of about 4 million cubic yards per year from the entrance channel. The North Jetty and Jetty A are located in Pacific County, Washington, near Ilwaco and Long Beach on the Long Beach Peninsula. The North Jetty was completed in 1917. Jetty A, positioned on the south side of the North Jetty, was constructed in 1939 to a length of 1.1 miles. Jetty A was constructed to direct river and tidal currents away from the North Jetty foundation. The South Jetty is located in Clatsop County, Oregon near Warrenton/Hammond and Astoria. The initial 4.5-mile section of the South Jetty was completed in 1895, with a 2.4-mile extension completed in 1913. Jetty construction realigned the ocean entrance to the Columbia River, established a consistent navigation channel that was 40 feet below mean lower low water (MLLW) across the bar, and significantly improved navigation through the MCR. Improvements made from 1930 to 1942 (including addition of Jetty A and Sand Island pile dikes) produced the present entrance configuration.

Prior to improvement in 1885, the tidal channels through the MCR shifted north and south between Fort Stevens and Cape Disappointment, a distance of about 5.5 miles. The controlling depth of dominant channel through the ebb tidal delta varied between 18 to 25 feet deep below MLLW. The ebb and flood tidal deltas at MCR entrance were distributed over a large area immediately seaward and upstream of the river mouth. Ships often had difficulty traversing the Columbia River bar, the area in which the flow of the estuary rushes headlong into towering ocean waves. On many occasions, outbound ships had to wait a month or more until bar conditions were favorable for crossing. To make navigating through the MCR even worse, sailing ships had to approach either of the two natural channels abeam to the wind and waves. The natural channels often shifted widely within the course of several tidal cycles. At best, crossing the bar was dangerous. At worst, it was not possible. Offshore of the MCR lies the vast expanse of the northeast Pacific Ocean. Inshore of the MCR lies the Columbia River and estuary, the coastal outlet for a drainage basin of 250,000 square miles.

The objective of the work described here was to conduct an Independent External Peer Review (IEPR) of the Mouth of Columbia River Major Rehabilitation Evaluation Report in accordance with procedures described in the Department of the Army, U.S. Army Corps of Engineers (USACE) Engineer Circular *Civil Works Review Policy* (EC No. 1165-2-209) (USACE, 2010), USACE CECW-CP memorandum *Peer Review Process* (USACE, 2007), and Office of Management and Budget (OMB) bulletin *Final Information Quality Bulletin for Peer Review* (OMB, 2004). Battelle, as a 501(c)(3) non-profit science and technology organization with experience in establishing and administering peer review panels, was engaged to coordinate the IEPR of the Mouth of Columbia River Major Rehabilitation Evaluation Report. Independent, objective peer review is regarded as a critical element in ensuring the reliability of scientific analyses.

This final report details the IEPR process, describes the IEPR panel members and their selection, and summarizes the Final Panel Comments of the IEPR Panel on the existing environmental, economic, and engineering analyses contained in the Mouth of Columbia River Major Rehabilitation Evaluation Report. The full text of the Final Panel Comments is presented in Appendix A.

2. PURPOSE OF THE IEPR

To ensure that USACE documents are supported by the best scientific and technical information, USACE has implemented a peer review process that uses IEPR to complement the Agency Technical Review (ATR), as described in USACE (2010) and USACE (2007).

In general, the purpose of peer review is to strengthen the quality and credibility of the USACE decision documents in support of its Civil Works program. IEPR provides an independent assessment of the economic, plan formulation, engineering, and environmental analysis of the project study. In particular, the IEPR addresses the technical soundness of the project study's assumptions, methods, analyses, and calculations and identifies the need for additional data or analyses to make a good decision regarding implementation of alternatives and recommendations.

In this case, the IEPR of the Mouth of Columbia River Major Rehabilitation Evaluation Report was conducted and managed using contract support from Battelle, which is an Outside Eligible Organization under Section 501(c)(3) of the U.S. Internal Revenue Code with experience conducting IEPRs for USACE.

3. METHODS

This section describes the method followed in selecting the members for the IEPR Panel (the Panel) and in planning and conducting the IEPR. The IEPR was conducted following procedures described by USACE (2010) and in accordance with USACE (2007) and OMB (2004) guidance. Supplemental guidance on evaluation for conflicts of interest (COIs) was obtained from the *Policy on Committee Composition and Balance and Conflicts of Interest for Committees Used in the Development of Reports* (The National Academies, 2003).

3.1 Planning and Schedule

After receiving the notice to proceed (NTP), Battelle held a kick-off meeting with USACE to review the preliminary/suggested schedule, discuss the IEPR process, and address any questions regarding the scope (e.g., clarify expertise areas needed for panel members). Any revisions to the schedule were submitted as part of the final Work Plan.

Table 1 defines the schedule followed in executing the IEPR. Due dates for milestones and deliverables are based on the NTP date of December 6, 2010. Note that the work items listed in Task 7 occur after the submission of this report. Battelle will enter the 25 Final Panel Comments developed by the Panel into USACE's Design Review and Checking System (DrChecks), a Web-based software system for documenting and sharing comments on reports and design documents, so that USACE can review and respond to them. USACE will provide responses (Evaluator Responses) to the Final Panel Comments, and the Panel will respond (BackCheck Responses) to the Evaluator Responses. All USACE and Panel responses will be documented by Battelle.

Table 1. Mouth of Columbia River IEPR Schedule

TASK	ACTION	DUE DATE
1	**NTP**	12/6/2010
	Review documents available	12/7/2010
	[a]Battelle submits draft Work Plan	12/15/2010
	USACE provides comments on draft Work Plan	12/20/2010
	[a]Battelle submits final Work Plan	12/28/2010
2	Battelle requests input from USACE on the conflict of interest (COI) questionnaire	12/8/2010
	USACE provides comments on COI questionnaire	12/9/2010
	[a]Battelle submits list of selected panel members	12/16/2010
	USACE provides comments on selected panel members	12/17/2010
	Battelle completes subcontracts for panel members	1/5/2011
3	[a]Battelle receives final charge from USACE (to be included in Work Plan)	12/10/2010
4	USACE/Battelle kick-off meeting	12/13/2010
	Battelle sends review documents to IEPR Panel	1/6/2011
	USACE/Battelle/Panel kick-off meeting	1/7/2011
	Battelle convenes mid-review teleconference for panel to ask clarifying questions of USACE	1/19/2011
5	Panel members complete their individual reviews	1/31/2011
	Battelle convenes panel review teleconference with IEPR Panel	2/10-2/11/2011
	Panel members provide draft Final Panel Comments to Battelle	2/21/2011
6	[a]Battelle submits Final IEPR Report to USACE	3/9/2011
7[b]	Battelle inputs Final Panel Comments to DrChecks; Battelle provides Final Panel Comment response template to USACE	3/10/2011
	Battelle convenes teleconference with USACE to review the requirements of the Evaluator Response process.	3/11/2011
	USACE provides draft Evaluator Responses and clarifying questions to Battelle	3/16/2011
	Battelle convenes teleconference between Battelle, Panel, and USACE to discuss Final Panel Comments, draft responses, and clarifying questions	3/23/2011
	USACE inputs final Evaluator Responses in DrChecks	3/30/2011
	Battelle inputs the Panel's BackCheck Responses in DrChecks	4/7/2011
	[a]Battelle submits pdf printout of DrChecks project file	4/8/2011
	Project Closeout	6/13/2011

[a] Deliverable

[b] Task 7 occurs after the submission of this report.

3.2 Identification and Selection of IEPR Panel Members

The candidates for the Panel were evaluated based on their technical expertise in the following key areas: design and construction engineering (coastal engineering), plan formulation, biology/ National Environmental Policy Act (NEPA), hydrology and hydraulics engineering/coastal engineering, geomorphology, and economics. These areas correspond to the technical content of the Mouth of Columbia River IEPR and overall scope of the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report project.

To identify candidate panel members, Battelle reviewed the credentials of the experts in Battelle's Peer Reviewer Database, sought recommendations from colleagues, contacted former panel members, and conducted targeted Internet searches. Battelle initially identified more than 28 candidates for the Panel, evaluated their technical expertise, and inquired about potential COIs. Of these, Battelle chose seven of the most qualified candidates and confirmed their interest and availability. Of the seven candidates, five were proposed for the final Panel and two were proposed as backup reviewers. Information about the candidate panel members, including brief biographical information, highest level of education attained, and years of experience, was provided to USACE for feedback. Battelle made the final selection of panel members according to the selection criteria described in the Work Plan.

The five proposed primary reviewers constituted the final Panel. The remaining candidates were not proposed for a variety of reasons, including lack of availability, disclosed COIs, or lack of the precise technical expertise required.

The candidates were screened for the following potential exclusion criteria or COIs.[1] These COI questions were intended to serve as a means of disclosure and to better characterize a candidate's employment history and background. Providing a positive response to a COI screening question did not automatically preclude a candidate from serving on the Panel. For example, participation in previous USACE technical peer review committees and other technical review panel experience was included as a COI screening question. A positive response to this question could be considered a benefit.

- Involvement by you or your firm[2] in the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Involvement by you or your firm[2] in any work related to deep draft navigation studies on the Columbia River.

[1] Battelle evaluated whether scientists in universities and consulting firms that are receiving USACE-funding have sufficient independence from USACE to be appropriate peer reviewers. See OMB (2004, p. 18), "….when a scientist is awarded a government research grant through an investigator-initiated, peer-reviewed competition, there generally should be no question as to that scientist's ability to offer independent scientific advice to the agency on other projects. This contrasts, for example, to a situation in which a scientist has a consulting or contractual arrangement with the agency or office sponsoring a peer review. Likewise, when the agency and a researcher work together (e.g., through a cooperative agreement) to design or implement a study, there is less independence from the agency. Furthermore, if a scientist has repeatedly served as a reviewer for the same agency, some may question whether that scientist is sufficiently independent from the agency to be employed as a peer reviewer on agency-sponsored projects."

- Involvement by you or your firm[2] in projects related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Involvement by you or your firm[2] in the conceptual or actual design, construction, or O&M of any projects related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Current employment by the U.S. Army Corps of Engineers (USACE).
- Involvement with paid or unpaid expert testimony related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- Current or previous employment or affiliation with members of any of the following cooperating Federal, State, County, local and regional agencies, environmental organizations, and interested groups: National Marine Fisheries Service, U.S. Fish and Wildlife Service, U.S. Geological Survey, Washington Department of Ecology, Oregon Department of Environmental Quality, Oregon Department of Land Conservation and Development, or Portland State University (for pay or pro bono).
- Past, current or future interests or involvements (financial or otherwise) by you, your spouse or children related to the mouth of the Columbia River.
- Current personal involvement with other USACE projects, including whether involvement was to author any manuals or guidance documents for USACE. If yes, provide titles of documents or description of project, dates, and location (USACE district, division, Headquarters, ERDC, etc.), and position/role. Please highlight and discuss in greater detail any projects that are specifically with the Portland District.
- Current firm[2] involvement with other USACE projects, specifically those projects/contracts that are with the Portland District. If yes, provide title/description, dates, and location (USACE district, division, Headquarters, ERDC, etc.), and position/role.
- Any previous employment by the USACE as a direct employee or contractor (either as an individual or through your firm[2]) within the last 10 years, notably if those projects/contracts are with the Portland District. If yes, provide title/description, dates employed, and place of employment (district, division, Headquarters, ERDC, etc.), and position/role.
- Previous experience conducting technical peer reviews. If yes, please highlight and discuss any technical reviews concerning deep draft navigation or coastal engineering, and include the client/agency and duration of review (approximate dates).
- Pending, current or future financial interests in contracts/awards from USACE related to the Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.
- A significant portion (i.e., greater than 50%) of personal or firm[2] revenues within the last 3 years came from USACE contracts.
- Any publicly documented statement (including, for example, advocating for or discouraging against) related to Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Major Rehabilitation Evaluation Report and technical appendices.

- Participation in relevant prior Federal studies relevant to this project, including:
  - U.S. Army Corps of Engineers. 1983. Columbia River at the Mouth Navigation Channel Improvement, Final Environmental Impact Statement, Oregon-Washington. Portland, Oregon.
  - Earth Sciences Associates and Geo Recon International. 1985. Geologic and Seismic Investigation of Columbia River Mouth Study Area, Report for U.S. Army Corps of Engineers, Portland District, Portland, Oregon.
  - Northwest Geophysical Associates, Inc. 1996. 1996 Columbia River Offshore Disposal Site Study, Sidescan Sonar Investigation, Report for U.S. Army Corps of Engineers, Portland District, Portland, Oregon.
  - U.S. Army Corps of Engineers. 1999. Integrated Feasibility Report for Channel Improvements and Environmental Impact Statement, Columbia and Lower Willamette River Federal Navigation Channel. Portland, Oregon.
  - NMFS. 2004. Endangered Species Act Section 7 Formal Consultation and Magnuson-Stevens Fishery and Conservation Management Act Essential Fish Habitat Consultation for the Columbia River North and South Jetties Rehabilitation, Columbia River Basin, Clatsop County, Oregon.
  - USACE. 2005. Interim Repair Decision Document for North and South Jetties at the Mouth of the Columbia River, Oregon and Washington. U.S. Army Corps of Engineers-Portland District, Portland, Oregon.
  - Global Remote Sensing. 2005. Mouth of the Columbia River Offshore Disposal Site Study, Multibeam Investigations, Report for U.S. Army Corps of Engineers, Portland District, Portland, Oregon.
  - Tetra Tech, Inc. April 2007. Wetland and Waters of the U.S. Delineation Revised Final Report: North Jetty, Mouth of the Columbia River, Pacific County, Washington. Prepared for U.S. Army Corps of Engineers, Portland, Oregon.
  - Tetra Tech, Inc. April 2007. Clatsop Spit Plant Communities Investigation and Mapping, Final Report: South Jetty, Mouth of the Columbia River, Clatsop County, Oregon. Prepared for U.S. Army Corps of Engineers, Portland, Oregon.
  - Ward, D. L., Melby, J.A., Myrick, G.B., and Henderson, W.G. 2007. Physical Model Study of Jetties at the Mouth of the Columbia River, Oregon and Washington. ERDC/CHL TR-07-XX. U.S. Army Corps of Engineers. Engineer Research and Development Center-Coastal and Hydraulics Laboratory. Vicksburg, Mississippi.
  - Demirbilik, Z., Lin, L, and Nwogu, O.G. 2008. Wave Modeling for Jetty Rehabilitation at the Mouth of the Columbia River, Oregon and Washington. ERDC/CHL TR-08-3. U.S. Army Corps of Engineers. Engineer Research and Development Center-Coastal and Hydraulics Laboratory. Vicksburg, Mississippi.
  - Moritz, H.R. and Moritz, H. P. 2009. Stochastic Risk-Based Life Cycle Simulation of Century Old Jetties at the Mouth of the Columbia River, USA. International Conference on Coasts, Marine Structures, and Breakwaters 2009. Proceedings of the Institution of Civil Engineers. Presented in Edinburgh, Scotland, September 2009.
- Participation in prior non-Federal studies relevant to this project.

- Is there any past, present or future activity, relationship or interest (financial or otherwise) that could make it appear that you would be unable to provide unbiased services on this project? If so, please describe:

In selecting the final members of the Panel from the list of candidates, Battelle chose experts who best fit the expertise areas and had no COIs. The five final reviewers were either affiliated with academic institutions or consulting companies or were independent engineering consultants. Battelle established subcontracts with the panel members when they indicated their willingness to participate and confirmed the absence of COIs through a signed COI form. USACE was given the list of candidate panel members, but Battelle made the final selections of the Panel. Section 4 of this report provides names and biographical information on the panel members.

Prior to beginning their review and within 2 days of their subcontracts being finalized, all members of the Panel attended a kick-off meeting via teleconference planned and facilitated by Battelle in order to review the IEPR process, the schedule, communication procedures, and other pertinent information for the Panel.

3.3 Preparation of the Charge and Conduct of the IEPR

Shortly after Battelle received NTP, USACE provided the following documents and reference materials. The documents and files in bold font were provided for review and the other documents were provided for reference or supplemental information only.

- **Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report**
  - **Appendix A1: Coastal Engineering**
  - **Appendix A2: Reliability Analysis, Event Tree Formulation and Life-Cycle Simulation**
  - **Appendix B: Geotechnical**
  - **Appendix C: Economics**
  - **Appendix D: Environmental Documentation**
  - **Appendix E: M-CACES Cost Estimate for Recommended Plan**
  - Appendix F: Project Management Plan
  - Appendix G: Schedule of Fully Funded Project Costs
- USACE guidance *Civil Works Review Policy* (EC 1165-2-209) dated January 31, 2010
- CECW-CP Memorandum dated March 31, 2007
- Office of Management and Budget's *Final Information Quality Bulletin for Peer Review* released December 16, 2004.

In addition, throughout the review period, USACE provided additional documents at the request of panel members. These additional documents were provided as supplemental information only and were not part of the official review:

- Jetty Rehab, Mouth of the Columbia River, USGS Draft v01 Appendix Figures, Edwin Elias and Guy Gelfenbaum 2007
- Jetty Rehab, Mouth of the Columbia River, USGS Draft v02, Edwin Elias and Guy Gelfenbaum 2007

- Analysis of Jetty Rehabilitation at the Mouth of the Columbia River, Washington/Oregon, USA Part: 2 Regional Circulation, Sediment Transport, and Morphology Change June 2007 ERDC/CHL Kenneth J. Connell and Julie Dean Rosati
- 2009 MCR Jetty inspection reports and supporting documentation
- Summary of the Jetty heads and the physical model
- Model Documentation Report
- Additional documentation on design criteria
- Appendix b geotechnical studies (as listed in the file name)
- Exhibit M Economic Analysis of the Columbia River Channel Improvement Project, Final Supplemental Integrated Feasibility Report and Environmental Impact Statement
- Economic spreadsheet models for each jetty
- Three AVIs and videos showing the velocity vectors at the MCR
- a summary of the Jetty heads and the physical model
- Mouth of the Columbia River North Jetty, South Jetty, and Jetty A Rehabilitation Template Examples
- Documentation sent to USACE Headquarters to obtain model approval for use.

Charge questions were provided by USACE and included in the draft and final Work Plans. In addition to a list of 78 charge questions/discussion points, the final charge included general guidance for the Panel on the conduct of the peer review (provided in Appendix B of this final report).

Battelle planned and facilitated a final kick-off meeting via teleconference during which USACE presented project details to the Panel. Before the meeting, the IEPR Panel received an electronic version of the Mouth of Columbia River IEPR documents and the final charge. A full list of the documents reviewed by the Panel is provided in Appendix B of this report. The Panel was instructed to address the charge questions/discussion points within a comment-response form provided by Battelle.

3.4 Review of Individual Comments

Prior to completion of the review of the Mouth of Columbia River IEPR documents, a teleconference with USACE, the Panel, and Battelle was held halfway through the review period to provide the Panel an opportunity to ask questions of USACE regarding uncertainties requiring clarification. At the end of the review period, the Panel produced approximately 500 individual comments in response to the charge questions/discussion points. Battelle reviewed the comments to identify overall recurring themes, areas of potential conflict, and other overall impressions. As a result of the review, Battelle summarized the 500 comments into a preliminary list of 44 overall comments and discussion points. Each panel member's individual comments were shared with the full Panel in a merged individual comments table.

3.5 IEPR Panel Teleconference

Due to the number of comments and the complexity of the issues, Battelle facilitated two 3-hour teleconferences with the Panel so that the panel members, many of whom are from diverse scientific backgrounds, could exchange technical information. The main goal of the teleconferences was to identify which issues should be carried forward as Final Panel Comments in the IEPR report and decide which panel member would serve as the lead author for the development of each Final Panel Comment. This information exchange ensured that the Final IEPR Report would accurately represent the Panel's assessment of the project, including any conflicting opinions. The Panel engaged in a thorough discussion of the overall positive and negative comments, added any missing issues of high-level importance to the findings, and merged any related individual comments. In addition, Battelle confirmed each Final Panel Comment's level of significance to the Panel.

The Panel also discussed responses to seven specific charge questions where there appeared to be disagreement among panel members. The conflicting comments were resolved based on the professional judgment of the Panel, and each comment was either incorporated into a Final Panel Comment, determined to be consistent with other Final Panel Comments already developed, or determined to be a non-significant issue.

At the end of these discussions, the Panel identified 30 initial comments and discussion points that should be brought forward as Final Panel Comments.

3.6 Preparation of Final Panel Comments

Following the teleconference, Battelle prepared a summary memorandum for the Panel documenting each Final Panel Comment (organized by level of significance). The memorandum provided the following detailed guidance on the approach and format to be used to develop the Final Panel Comments for the Mouth of Columbia River IEPR:

- Lead Responsibility: For each Final Panel Comment, one Panel member was identified as the lead author responsible for coordinating the development of the Final Panel Comment and submitting it to Battelle. Battelle modified lead assignments at the direction of the Panel. To assist each lead in the development of the Final Panel Comments, Battelle distributed the merged individual comments table, a summary detailing each draft final comment statement, an example Final Panel Comment following the four-part structure described below, and templates for the preparation of each Final Panel Comment.
- Directive to the Lead: Each lead was encouraged to communicate directly with other IEPR panel members as needed and to contribute to a particular Final Panel Comment. If a significant comment was identified that was not covered by one of the original Final Panel Comments, the appropriate lead was instructed to draft a new Final Panel Comment.
- Format for Final Panel Comments: Each Final Panel Comment was presented as part of a four-part structure:
    1. Comment Statement (succinct summary statement of concern)
    2. Basis for Comment (details regarding the concern)
    3. Significance (high, medium, low; see description below)
    4. Recommendation(s) for Resolution (see description below).
- Criteria for Significance: The following were used as criteria for assigning a significance level to each Final Panel Comment:

1. High: Describes a fundamental problem with the project that could affect the recommendation, success, or justification of the project. Comments rated as high indicate that the Panel analyzed or assessed the methods, models, and/or analyses and determined that there is a "showstopper" issue.
2. Medium: Affects the completeness of the report in describing the project, but will not affect the recommendation or justification of the project. Comments rated as medium indicate that the Panel does not have sufficient information to analyze or assess the methods, models, or analyses.
3. Low**:** Affects the understanding or accuracy of the project as described in the report, but will not affect the recommendation or justification of the project. Comments rated as low indicate that the Panel identified information (tables, figures, equations, discussions) that was mislabeled or incorrect or data or report sections that were not clearly described or presented.

- Guidance for Developing Recommendation: The recommendation section was to include specific actions that USACE should consider to resolve the Final Panel Comment (e.g., suggestions on how and where to incorporate data into the analysis, how and where to address insufficiencies, areas where additional documentation is needed).

Battelle reviewed and edited the Final Panel Comments for clarity, consistency with the comment statement, and adherence to guidance on the Panel's overall charge, which included ensuring that there were no comments regarding either the appropriateness of the selected alternative or USACE policy. At the end of this process, 25 Final Panel Comments were prepared and assembled; four of the original 30 comments were merged with other existing Final Panel Comments and one was deleted because it did not meet the criteria for significance for Final Panel Comments. There was no direct communication between the Panel and USACE during the preparation of the Final Panel Comments; however, Battelle sent working drafts of the Final Panel Comments to USACE as a means to help them get a head start in providing responses to the Panel comments. Battelle informed USACE that these working drafts could be revised, merged, deleted, or new comments created prior to the submittal of the Final IEPR Report. The Final Panel Comments are presented in Appendix A of this report.

4. PANEL DESCRIPTION

Candidates for the Panel were identified using Battelle's Peer Reviewer Database, targeted Internet searches using key words (e.g., technical area, geographic region), searches of websites of universities or other compiled expert sites, and referrals. Battelle prepared a draft list of primary and backup candidate panel members (who were screened for availability, technical background, and COIs), and provided it to USACE for feedback. Battelle made the final selection of panel members.

An overview of the credentials of the final five primary members of the Panel and their qualifications in relation to the technical evaluation criteria is presented in Table 2. More detailed biographical information regarding each panel member and his or her area of technical expertise is presented in the text that follows the table.

Table 2. Mouth of Columbia River IEPR Panel: Technical Criteria and Areas of Expertise

	Phillips	Cuba	Rein	Sultan	Maher	Sultan
Civil Design/Construction [Coastal Engineering] (one expert needed)	**X**					
Minimum 10 years experience in civil design/construction and coastal engineering	X			X		X
Familiar with large, complex Civil Works projects with high public and interagency interests	X			X		X
Experience performing coastal engineering design and construction management for coastal projects	X			X		X
Familiar with similar projects across the United States and related coastal engineering	X			X		X
Experience in computer modeling including Matlab experience in coastal engineering	X			X		X
Familiar with construction industry and practices used in coastal construction in the Pacific Northwest	X			X		X
Degree in civil engineering	X			X		X
Plan Formulation (one expert needed)		**X**				
Minimum 10 years experience in the plan formulation process		X		X		X
Familiar with large, complex Civil Works projects with high public and interagency interests		X		X		X
Familiar with evaluation of alternative plans for coastal projects		X		X		X
Familiar with USACE standards and procedures		X		X		X
Degree in planning or a related field		See waiver*				
Biology NEPA (one expert needed)			**X**			
Minimum 10 years experience in biology		X	X			
Familiar with large, complex Civil Works projects with high public and interagency interests		X	X			
Particular knowledge of ecosystem restoration		X	X			
Familiar with all NEPA requirements		X	X			
Minimum of an M.S. degree in Biology		X	X			
Hydrology and Hydraulics Engineering/Coastal				**X**		

	Phillips	Cuba	Rein	Sultan	Maher	Sultan
Engineering (one expert needed)						
Minimum 10 years experience in hydrology and hydraulics engineering				X		X
Familiar with large, complex Civil Works projects with high public and interagency interests				X		X
Experience with sediment transport and engineering analyses related to design to include a variety of materials and cross-sections				X		X
Familiar with standard USACE hydrologic and hydraulic computer models used in jetty design				X		X
Minimum of an M.S. degree in civil engineering or hydrology and hydraulics				X		X
Registered professional engineer				X		X
Economics (one expert needed)					**X**	
Minimum 10 years experience in economics				X	X	X
Familiar with large, complex Civil Works projects with high public and interagency interests				X	X	X
Able to evaluate the appropriateness of cost effectiveness and incremental cost analysis (CE/ICA), as applied to USACE projects				X	X	X
Experience with National Economic Development (NED) analysis procedures, particularly as they relate to jetty construction projects					X	
Degree in economics or related field				X	X	X
Geomorphology (one expert needed)						**X**
Minimum 10 years experience in geomorphology				X		X
Familiar with large, complex Civil Works projects with high public and interagency interests				X		X
Experience with geological analyses related to project design to include a variety of materials and cross-sections used in jetty design				X		X
Minimum M.S. degree in civil engineering or geology				X		X
Registered professional engineer				X		X

* Dr. Tom Cuba has 28 years of experience in planning and biology/ecology. Dr. Cuba does not have his degree in planning or a related field. He has his Ph.D. in marine science/ecology. Battelle believes that his planning experience is commensurate with a degree in planning.

Shane Phillips, P.E.

Role: This panel member was chosen primarily for his coastal engineering design and construction management for coastal projects experience and expertise.
Affiliation: Coast and Harbor Engineering, Inc.

Shane Phillips, **P.E.,** a principal civil engineer at Coast and Harbor Engineering, Inc. in Edmonds, Washington, has 17 years of experience in marine and coastal engineering. He earned his B.S. in civil engineering in 1993 from Washington State University and is a registered professional engineer in Washington, California, Texas, Louisiana, and Florida. His specific engineering experience includes the feasibility evaluation, preliminary design, and final design of geotechnical, structural, and civil components of coastal and marine construction projects.

Mr. Phillips has applied his coastal engineering design expertise to a variety of coastal shore protection projects along the Pacific Northwest coast and has served as both on-site resident engineer and project manager on coastal construction projects including jetty, revetments, levees, dredging, and boating facilities. He served as project and design engineer for the North Jetty Beachfront Properties Coastal Erosion project in Ocean Shores, Washington, which involved the design and construction of a 1,000 foot long rock revetment structure.

Mr. Phillips has managed and executed feasibility studies, planning studies, and engineering of coastal and marine construction projects for port facilities, marinas, boating facilities, ferry terminals, marine terminals, navigation channels, and shoreline properties. He was Project Engineer for preliminary and final engineering design phase on the Willapa Bay, Washington SR-105 Emergency Stabilization Project consisting of a 1,400 foot long rock groin, 1,200 foot long submerged rock jetty and 1,100 feet of beach nourishment.

Coastal design experience includes the layout and design of floating breakwaters, groins, piers, bulkheads, beach nourishment, shoreline stabilization, dredging, water quality improvement, and nearshore restoration. Structural design experience includes the evaluation and engineering design of marine terminals, piers, bulkheads, retaining walls, breakwaters, and marinas using concrete, steel, and timber materials. Mr. Phillips has reviewed/verified computer modeling preparation and calibration and regularly works with engineering programs including AutoCad 2010, PCSTBLE, ACES, Surfer, SMS, Matlab, and Land Development.

Tom Cuba, Ph.D.

Role: This panel member was chosen primarily for his experience and expertise in the coastal plan formulation process.
Affiliation: Delta Seven, Inc.

Thomas R. Cuba, Ph.D., CEP, President and Chief Scientist at Delta Seven, Inc., serves as a Research Scientist at Stillwater Research Group, and is a research adjunct professor at the University of South Florida. He earned his Ph.D. in marine ecology from the University of South Florida in 1984. Dr. Cuba has 28 years of planning experience, which includes developing management plans for a variety of Florida watersheds and aquatic preserves, working on waterfront infrastructure feasibility plans, and designing wetland, pond, and seagrass restoration plans. Dr.Cuba’s six-year service as a Naval Intelligence Officer included plan formulation responsibilities, and he has been involved in civil and governmental plan formulation of engineered ecological restoration projects since 1984. Additionally, he conducted comprehensive conservation and public works plan formulation for Pinellas County, Florida and subsequently worked to enact these plans through public projects and codification in county ordinances.

Dr. Cuba has served as project manager and chief scientist on several watershed-based management and restoration projects (all of which included construction elements) and, for many of these, he acted as chair of the multi-stakeholder board. Dr. Cuba has assessed alternatives in beach nourishment and the placement of jetties and groins during his work with Pinellas County and in private practice. He is familiar with USACE plan formulation standards and procedures and has served on four USACE IEPR panels in the recent past as plan formulator (Clear Creek, C-111, Tamiami Trail, and LCA6).

Felicia Orah Rein, Ph.D.

Role: This panel member was chosen primarily for her biology/NEPA experience and expertise.
Affiliation: Watershed Solutions, Inc. and Florida Atlantic University

Felicia Orah Rein, Ph.D., is president and senior scientist at Watershed Solutions, Inc., an environmental consulting and restoration services firm specializing in environmental restoration, environmental assessments and impact analyses, ecological monitoring, water resource management, and reduction of sediment transport and erosion. She is also an affiliate professor at Florida Atlantic University. She earned her Ph.D. in ecosystem science/restoration ecology from the University of California at Santa Cruz in 2000 and has more than 20 years of experience managing and implementing large-scale multidisciplinary restoration ecology and resource protection projects.

Dr. Rein has extensive experience with large complex Civil Works projects with high public visibility, including assessment of environmental impacts of the New York/New Jersey Harbor deepening project for which she provided expertise in dredged material beneficial uses and source reduction and conducted vegetation and wetland mapping on coastal sites. Her NEPA expertise has involved collaboration with the National Marine Fisheries Service, California Department of Fish and Game, California State Water Resource Control Board, and U.S. Fish and Wildlife Service. She has a strong knowledge of ecosystem restoration, having worked on projects such as the Far Rockaway, Averne site park and housing development projects. Her role included wetland restoration areas and focused on water quality and vegetation impacts. Dr. Rein has prepared numerous Phase I (NEPA) environmental site assessments and is familiar with all NEPA requirements. As a senior project manager, she has provided scientific expertise on environmental documents according to NEPA guidelines and worked closely with local, state, and Federal government, as well as lawyers, environmentalists, and community groups on complex water rights assessments. She has experience in wetland ecology of urban regions, having worked in the initial phases of the fast-tracked wetland restoration projects in the NY/NJ region, including the hydrologic restoration of Liberty State Park and others.

She has conducted technical peer reviews, quality assurance/quality control (QA/QC) reviews, and acted as an expert consultant in environmental damage disputes for engineering and consulting firms. Dr. Rein is a member of Sigma Xi National Scientific Research Society.

Nels Sultan, P.E., Ph.D.

Role: This panel member was chosen to serve in a **dual role** for his hydrology and hydraulic engineering and geomorphology experience and expertise.
Affiliation: PND Engineers, Inc.

Nels Sultan, P.E., Ph.D., a coastal engineer at PND Engineers, Inc. in Seattle, Washington, has more than 20 years of experience specializing in the analysis and design of waterfront projects, including coastal geomorphology, coastal numerical models, and wave tank physical models. He earned his Ph.D. in ocean engineering from Texas A&M University in 1995. He is a registered professional civil engineer in Washington and Alaska and is a former officer in the Naval Reserve, Civil Engineering Construction Corps.

Dr. Sultan has worked on all aspects of design engineering for ports, harbors, shore protection, dredging, and other coastal and marine facilities projects. His extensive project experience includes preparing plans, specifications, and cost estimates through final design and construction (using a variety of materials including rock, geocontainers, stone masonry, and concrete), in addition to analyzing wave conditions, coastal processes, and sediment transport. Dr. Sultan’s experience includes serving as the ocean engineer on the South Jetty Permeability project in Grays Harbor, Washington, where the jetty is subject to erosion of sediment at its landward end and has been completely severed from the mainland on occasion. Dr. Sultan analyzed aerial photographs, wind, wave, and tide conditions in order to determine whether the south jetty was permeable to sediment transport and contributing to erosion problems.

He served as project manager and coastal engineer for the Skagway Small Boat Harbor Dredging and Entrance Surge Control project in Alaska and led design and construction support services for a new 290 foot long, curved, partially penetrating vertical breakwater that provided surge control at the harbor entrance. Also for this project, Dr. Sultan prepared a wind and wave study for breakwater alternatives and provided computer modeling, using both desktop and CGWAVE modeling of wave transmission, wave diffraction, and reflected waves to evaluate waves at the adjacent ferry terminal floating dock and the shoreline north of the planned wave barrier. He also served as the ocean engineer for the Willapa Bay, WA SR-105 Stabilization Project Monitoring Program, which involved beach nourishment, an underwater dike, and a multi-purpose rock groin.

Dr. Sultan is a member of the Association of Coastal Engineers, American Society of Civil Engineers and the American Geophysical Union.

Daniel Maher, M.S.
Role: This panel member was chosen primarily for his experience and expertise in economics.
Affiliation: G.E.C., Inc.

Daniel Maher, M.S., is a senior economist and project manager at G.E.C., Inc. with 22 years of experience conducting large water resource/public works planning studies. He received his M.S. in agricultural economics from Louisiana State University in 1988. Mr. Maher has served as a project manager or economist on numerous regional economic impact, navigation, water supply, recreation, flood control, and ecosystem restoration projects. Mr. Maher has developed benefits and costs for National Economic Development (NED) analyses of large water resource planning efforts and navigation projects, which involved using methodologies estimating project benefits of coastal construction projects based on transportation savings. For example, Mr. Maher was the economist and project manager responsible for estimating NED benefits associated with increasing the current authorized depth of the federal central harbor and navigation channels to the Tenth Avenue Marine Terminal in San Diego, California. The primary benefits of deepening the harbor were the reduction in vessel operating costs by allowing deeper draft vessels to traverse the channel fully loaded, and the reduction or elimination of vessel tidal delays. Additionally, he was responsible for estimating the NED benefits and assessing the operational and environmental impacts resulting from the removal of several underwater natural obstructions in San Francisco Bay. These underwater pinnacles are considered a major hazard to navigation in the bay, especially regarding deep-draft oil tankers. The economic feasibility of removing these pinnacles was based on quantifiable transportation savings resulting from reduced bay transit distances of oil tankers and container vessels that frequent the ports on the bay.
Mr. Maher has also been responsible for cost effectiveness/incremental cost analysis (CE/ICA) for several USACE ecosystem restoration projects including Canonsburg Lake Ecosystem Restoration Project (Pittsburg District); Licking River Watershed and Dillon Lake Ecosystem Restoration Project (Huntington District); and Big Sunflower Ecosystem Restoration Feasibility Study (Vicksburg District). For each of these projects Mr. Maher worked with biologists and ecologists to define appropriate metrics for measuring environmental benefits and converting benefits to an average annual basis for each alternative considered. He also reviewed construction and operations and maintenance costs associated with each alternative, and conducted cost effective analysis and incremental cost analysis using IWR-PLAN. Mr. Maher has experience with numerous economic computer programs, including IMPLAN Economic Impact Software, IWR-Planning Suite, and IWR-MAIN Water Use Forecast System.

5. SUMMARY OF FINAL PANEL COMMENTS

The panel members agreed among one another on their "assessment of the adequacy and acceptability of the economic, engineering, and environmental methods, models, and analyses used" (USACE, 2010; p. D-4) in the Mouth of Columbia River IEPR. Table 3 lists the 25 Final Panel Comment statements by level of significance. The full text of the Final Panel Comments is presented in Appendix A. Of primary significance, and as discussed in several of the Final Panel Comments, the Panel has serious concern with the SRB model and the potentially over-emphasized role it played in the evaluation of alternatives, engineering design, and economic analyses. The following statements summarize the Panel's findings.

Plan Formulation Rationale: From a planning perspective, the Major Rehabilitation Evaluation Report is well done and in compliance with all of the typical formulation steps; however, it was never clearly explained that the scope of work was limited to the repair and rehabilitation within the present configuration, nor why it was limited in this manner. Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected. The Panel agreed that the SRB model is not a substitute for conventional engineering and economic analyses and should not be a stand-alone analysis for selecting a recommended plan.

Economics: The Panel identified three major issues in the economic analysis: (1) inconsistencies in the Major Rehabilitation Evaluation Report and economic spreadsheet models; (2) the assumption that navigation would not be impacted; and (3) the formulation of the base condition. Inconsistencies in the report and economic spreadsheet models pertaining to the calculation of NPVs and AACs prevented the Panel from validating the economic analysis. Based on the assumption that navigation will not be impacted, a least cost analysis was used in lieu of a transportation cost savings analysis to calculate NED benefits. Conflicting assumptions concerning the ability to maintain navigation invalidate the logic behind calculating NED benefits using a least cost analysis. As the project is currently formulated, the base condition maintenance strategy for the MCR jetties conforms most closely with the fix-as-fails strategy, while the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits. Each of these issues could impact the selection of the NED plan, which was selected as the recommended plan.

Engineering: There are serious technical difficulties with the Major Rehabilitation Evaluation Report and analyses. The report lacks a set of design criteria, including project life, standards of performance to be met, and environmental conditions with return period events. All are part of conventional coastal engineering design practice. The SRB model cannot be verified and does not include important processes. Major questions remain that have not been adequately investigated for this level of study, including subsurface geotechnical properties, feasibility of proposed barge offloading/material re-handling facilities, and the long term stability of the jetty foundations assuming continued erosion and loss of nearshore sediment. The report indicates that large volumes of sediment will move into the navigation channel after a breach event. However, the data and analysis do not support this conclusion. Additionally, is no clear discussion of the role of maintenance or emergency dredging, especially under extreme winter conditions. Detailed construction cost estimates also need to be provided in order for the cost analysis to be complete and verifiable. Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition.

Environmental: There is no discussion in the main report of sea level rise and potential wave height increases and its impact on this project over the 50+ year project timeline, given that the regional wave climate has been documented as more severe in the last 10 years. This has potential impacts to the project and in designing a project with lower long-term maintenance costs. Potential environmental impacts on sensitive species, upland habitats, and water quality as well as potential impacts to recreational use during project construction are not comprehensive nor adequately described in the mitigation plan. Finally, the alternatives are limited to armoring the existing configuration of the jetties and may not satisfy NEPA directive for alternative analysis.

Table 3. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel

Significance – High	
1	The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.
2	The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.
3	The underlying assumption that navigational impacts will not occur is not substantiated.
4	The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
5	The base condition, as formulated, does not represent the current O&M practice.
6	The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
7	The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.
8	The models and analyses of jetty failure do not include all significant processes.
Significance – Medium	
9	The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
10	A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
11	Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.
12	Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.
13	Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.
14	Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.
15	There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.

Table 3. Overview of 25 Final Panel Comments Identified by the Mouth of Columbia River IEPR Panel, continued

Significance – Medium	
16	The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.
17	The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
18	The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.
19	Risk thresholds for selected alternatives are not clearly defined.
20	It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
21	The model output parameters and wave height components are not clearly explained and supported.
22	The culvert installation details, as well as potential impacts, need further clarification.
Significance – Low	
23	The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
24	Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.
25	Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.

APPENDIX A

Final Panel Comments

on the

Mouth of Columbia River IEPR

This page is intentionally left blank.

Comment 1:
The economic analysis used to select the National Economic Development (NED) plan cannot be validated, nor can it be determined if assumptions were applied correctly in the economic spreadsheet models.
Basis for Comment:
Economics is the key consideration in evaluating the NED plan, which was selected as the recommended plan. Several issues were identified in the review documents and the economic spreadsheet models that could significantly change the outcome of the economic analysis and the selection of the recommended plan. These issues primarily pertain to the calculation of net present values (NPVs) and Average Annual Costs (AACs), and the presentation of the economic analysis results. **Calculation of NPVs and AACs** • The AACs, based on the NPVs presented in Table 2-1 and Table 2-2, appear to be based on a Federal discount rate of 4.125%, not 4.375%, as stated in the report. • The calculation of the NPVs and AACs in the economic spreadsheet model for the North Jetty are based on a discount rate of 4.125%, not 4.375%, as stated in the report. • The period (actual calendar years) of the annual stream of costs used to calculate the NPVs for each alternative differ between alternatives in the economic spreadsheet models; also, the actual calendar years included in these periods were not stated in the report. • The unit costs for jetty repair and dredging, as presented in the SRB model, are increased over time such that after 50 years, costs will be 15% greater than at present. In accordance with ER 1105-2-100, p. 2-11 (USACE, 2000), when conducting economic analysis, prices should be held constant over the period of analysis. **Presentation of Results** • The NPVs and AACs in the spreadsheets for the North Jetty and South Jetty differ from the results presented in the report. • The term NED, the process of calculating NED benefits, and the method of selecting the NED plan are not explained in Section 2 or Appendix C of the report. • The SRB model uses Monte Carlo simulation to increase the confidence of life cycle estimates and allow for evaluation of variance by producing project cost output, including mean and standard deviation values (Appendix A2, p. A2-49). The risk and uncertainty associated with estimating the stream of annual costs and the resulting NPVs, AACs, and benefit-to-cost (B/C) ratios are not addressed in the economic analysis. • The costs of the NED plan of $250 million in the Executive Summary are presented on a fully funded basis, whereas the costs in the main report are presented as NPVs, resulting in confusion.
Significance – High:
The inability to validate the economic analysis and the assumptions used in the economic spreadsheet model could impact the selection of the NED, or recommended plan.

Recommendations for Resolution:
1. Calculate the NPVs and AACs using the FY10 Federal discount rate of 4.375% for all alternatives; basing the NPVs on the stream of project costs for the 50-year period of analysis. 2. In accordance with ER 1105-2-100, Chapter 2 (USACE, 2000), revise the formulas in the economic spreadsheet models to reflect the same period of analysis for all alternatives. 3. State the years (annual stream of costs) used in calculating the NPV for each alternative and ensure consistency in alternative evaluation. 4. In accordance with ER 1105-2-100, Chapter 2, p. 2-11 (USACE, 2000), revise the repair and dredging costs to reflect the general level of prices prevailing during or immediately preceding the period of planning for the entire period of analysis. 5. Revise Section 2 and Appendix C of the report to include a definition of the term NED, an explanation of the process of calculating NED benefits, and the method of selecting the NED the plan. 6. In accordance with EP 1130-2-500, Appendix B, p. B-9 (USACE, 1996), report the results of all alternatives in a table displaying the mean net benefits and standard errors of each; providing the 90% confidence interval for the mean net benefits (mean+ 1.64x standard error). 7. Present the costs of the NED plan in the Executive Summary and the main report in both a fully funded basis and in NPV.

Comment 2:

The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.

Basis for Comment:

The report describes large volumes of sediment that will move into the navigation channel after a breach event. However, the Coastal Modeling System (CMS) numerical model results (CHL, 2007; p. 15, Figure 3.2) indicate minimal sediment movement through a jetty breach, even with the model strongly distorted to encourage movement. Similarly, historic breach events at the MCR inlet and region do not support the sediment movement volumes and rates assumed, nor the assumed sudden jetty failure, and the consequent requirement for emergency repairs and dredging.

The assumed jetty breach sediment movement is also inconsistent with recent experience with dredged material disposal at the North Jetty. Approximately 400,000 cubic yards were placed at the site each year during 1999-2008, on average, comparable to some jetty breach scenarios. However, the sediment placed at the North Jetty does not appear to have affected navigation. Similarly, the reported "rapid deterioration" of the North Jetty from 1999 to 2004, when 100,000 cubic yards of sediment leaked through the jetty leading to the repairs in 2005, is not consistent with the assumed scenario of a sudden breach event and large sediment movement.

Figures A1-252 to A1-254 of jetty breach sediment movement appear to be artist renderings, not products of analysis. The figures are misleading if they are interpreted as model output. Table 3-10 in the main report is presented but not explained, so there is no clear basis for the "Range of Volume Left in Channel" resulting from a breach of the North Jetty. There is no discussion of any hydrodynamic analysis or evaluation of morphologic changes and corresponding sedimentation of the navigation channel.

Significant inconsistencies are present in the sediment transport discussion. For example, the documents discuss sediment disposal practices at the shallow water site (SWS), immediately offshore from the tip of the North Jetty. The EA notes, "Active monitoring and evaluation determined that 80% to 95% of the dredged sand annually placed at the SWS moves northward onto Peacock Spit" (dispersed to the north). However, the main report describes how rip currents along the north side of the North Jetty transport sediment towards the tip and then south into the navigation channel. This implies an unrealistic discontinuity in the sediment budget and sediment paths immediately offshore of the jetty tip. The sediment budgets and analysis are not consistent in different parts of the review documents, and seem to vary depending on whether the analysis is centered on dredged material disposal (emphasizing sediment movement onto nearby shores) or jetty stability (emphasizing sediment movement towards the channel).

The jetties are described as functioning like "wingdams" preventing sediment movement into the channel. However, it seems more the case that the North Jetty shields the sands of Benson Beach from the dominant southwesterly waves preventing/slowing longshore sediment transport to the north, rather than south into the channel. Also, the process of sediment movement through a jetty breach is not at all like water through a dam break. The jetties are essentially a pyramid with only a small tip extending above water. What happens below water, with the sediments and foundations, is more central to the long term function and stability of the MCR jetties, navigation channel, and adjacent beaches.

A better analysis of sediment transport is needed because the repair alternatives at present are an ever expanding pile of rock on an ever shrinking foundation of sand. The geological history includes more than 225 million cubic yards of dredging since 1956 from the MCR navigation channel, with most disposed offshore (EPA, 2009). The Southwest Washington Coastal Erosion Study (Gelfenbaum, et al, 2006) concluded, "The carrying capacity of beach sands of Columbia River to the estuary has been reduced by approximately two-thirds over the last century." The missing sediment from the system and ongoing erosion of the shoals that help protect the jetties all point toward a need for a more rigorous investigation of sediment transport and alternatives that could reduce the loss of sediment and subsequent project O&M costs.

Significance – High:

The rehabilitation project will not be successful if ongoing sediment loss continues and the shoals and jetty foundation wash away.

Recommendations for Resolution*:*

1. Eliminate or justify the unrealistic assumption of sudden jetty failure and large volumes of sediment rapidly moving into the navigation channel. Instead, compare alternatives based on life-cycle costs including ordinary jetty repairs and maintenance dredging costs.
2. Provide a real analysis of sediment transport. Include review and reference to data and findings from maintenance dredging records and the studies of the MCR prepared for the multi-agency Southwest Washington Coastal Erosion Study.
3. Describe how implementation of this project will reduce ongoing erosion of the shoals.

Comment 3:
The underlying assumption that navigational impacts will not occur is not substantiated.
Basis for Comment:
The report clearly explains why navigation benefits were not analyzed. The method used to calculate NED benefits is based on the assumption that navigation will not be affected; the economic analysis is therefore based on a least cost analysis. This assumption, however, is not supported by the analysis presented in the report. A North Jetty breach in the winter is assumed to result in immediate mobilization of sediment that may impact navigation. If this assumption is true, it does not necessarily follow that emergency dredging will successfully occur to enable deep draft vessel access. As stated on p. 3-14 of the main report, under base conditions, during winter months, emergency jetty repairs and emergency dredging may not be possible, potentially resulting in impacts to navigation until the emergency activities are completed. The main report also states (p. 1-48) that operating a hopper dredge at the MCR during winter months has not yet been attempted. The report does not address the impact of project construction and dredging activities on navigation. For example, the operation of a dredge in the MCR, especially under extreme winter conditions, could have an adverse impact on navigation in the MCR. The Panel was unable to fully understand the potential impacts on navigation of shoaling resulting from a jetty breach. Since navigation benefits were not evaluated, impacts to the MCR or Lower Columbia River (LCR) channels as a result of shoaling after a jetty breach, in the absence of emergency dredging, is only presented in qualitative terms such as “navigation would be significantly impaired” (p. A2-34). The extent of the impacts are not described (i.e., bar closure, vessels delayed due to having to use tides to access the channel, reduced under-keel clearances, vessel lightloading, etc.). Due to the dismissal of potential navigation impacts, no mitigation is defined.
Significance – High:
Conflicting assumptions concerning impacts to navigation invalidate the logic behind calculating NED benefits using a least cost analysis and impacts the selection of the NED, or recommended, plan.
Recommendations for Resolution:
1. Conduct a transportation cost savings analysis to calculate NED benefits. 2. Include a description of the expected channel depths available after a breach event, and in the absence of emergency dredging, include a description of the portion of the fleet using the channel that will be impacted by the resulting shoaling.

Comment 4:
The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.
Basis for Comment:
The SRB model results cannot be verified, as it is a custom-made engineering and economics model applicable only to this project and there is no means for the Panel to examine the inner workings of the SRB model and its internal calculations to assess its "adequacy and acceptability". It is not possible to verify model results, or to repeat the application of the SRB model because there is no User's Manual or detailed description of model inputs and how the model was applied for the Mouth of Columbia River project. Furthermore, the model has not been peer reviewed or tested. Without documentation of successful application, the Panel cannot validate the model or have confidence in the results. The SRB model internal calculations and logic are not a commonly applied method for calculating rubble mound structure reliability and damage. The model analyzes more than 600 variables, stacking process upon process, each with wide error bars, resulting in the accumulation of errors. Significant processes do not appear to be included in the model, such as armor rock breakage and deterioration and deep seated slip-circle failures. Figure A2-18a shows model output for jetty cross-section progressive damage. This figure provides one of the few insights into the inner workings of the SRB model. The figure indicates the physics and process of jetty decay are not modeled correctly because the output is not consistent with cross-sections of observed damage. The engineering evaluation does not include much about the physical modeling (i.e., wave tank results). It seems the wave tank model was used to develop the input and equations within the numerical SRB model. It is more conventional to proceed in the opposite sequence, to use a wave tank model to verify a final design concept and verify numerical model predictions. The wave tank model effort was substantial and likely yielded good insights. However, it does not appear that results were used to their fullest potential because the model output and findings were only applied through the SRB model process. The wave tank model results could have been used as part of an independent evaluation, providing an additional line of evidence along with other investigations, data, and findings. The SRB analysis should only be used as one of many tools in the alternatives evaluation rather than a substitute for the preliminary engineering design. Additional engineering analysis and design documentation needs to be provided as part of the preliminary engineering design report. Documentation through the preliminary engineering design process will lead to improved confidence and reliability of SRB analysis.
Significance – High:
The SRB model functions as a "black box" and does not allow an alternatives analysis that is clearly based on sound technical evidence of engineering design performance.

Recommendations for Resolution:

1. Move the SRB model to an appendix, as supplemental information, and assign it a weight of 10% in the evaluation of alternatives. No further work on the SRB model is recommended as part this project.
2. Include a detailed description of the SRB model application allowing verification of model calculations and how the model was applied to the Mouth of Columbia River project.
3. Demonstrate that the model has been peer reviewed and tested.
4. Move the calculations and elements of the study currently within the SRB model (such as rubble-mound damage, slope stability failure, design wave heights and water levels, economic calculations, and much more) out of the SRB model and provide as separate calculations that can be checked and verified.
5. Provide documentation of preliminary engineering analysis and design which would constitute the basis for the SRB analysis. The preliminary engineering analysis should be provided in the report, with details in appendices. Elements that appear missing or inadequate at this level of design include the following:
    - Design criteria and basis of design
    - Structure condition assessment and existing condition survey
    - Subsurface geotechnical investigation
    - Development of jetty repair/rehabilitation alternatives
    - Hydrodynamic analysis (waves, currents, sediment transport) specifically related to the alternatives
    - Determination of stone sizing for alternatives
    - Alternative evaluation
        - Development of evaluation criteria
        - SRB analysis
    - Detailed volume and cost estimate for the alternatives.

Comment 5:
The base condition, as formulated, does not represent the current O&M practice.
Basis for Comment:
The present and future base condition maintenance strategy for the MCR jetties, as currently described in the report, conforms most closely with the fix-as-fails strategy. Under this scenario, jetties will be allowed to deteriorate to the point that just-in-time repairs may not prevent a breach in the jetty, which would result in expensive, winter dredging activities. As the project is currently formulated, the base condition life-cycle costs are the basis for estimating project benefits for all action alternatives. Historical maintenance efforts for MCR jetties are best described by an interim repair strategy. As a result of monitoring and advance repair activities, historically there have been no jetty breaches that have impacted navigation, nor has winter dredging been needed to maintain navigation. EP 1130-2-500, Appendix C, p. C-1 (USACE, 2006) states that for Major Rehabilitation Projects, under the base condition, "maintenance is increased as needed (but within limits) and components or sub-features are repaired on an emergency basis. This essentially represents the current O&M practice." Based on the report, this condition would resemble an interim repair strategy, rather than the fix-as-fails strategy currently described as the base condition.
Significance – High:
Inaccurate formulation of the base condition may increase life cycle costs, and may erroneously escalate project benefits for all action alternatives thus impacting the benefit to cost ratios.
Recommendations for Resolution:
1. Refine the base condition to more closely resemble the current O&M practice, in accordance with EP 1130-2-500, Appendix C (USACE, 1996).

Comment 6:
The reported analysis and design to mitigate a potential breach of the foreshore dune at the South Jetty root is not adequate.
Basis for Comment:
Potential breaching of the foreshore dune at the South Jetty root, to form a new connection to Trestle Bay, is discussed briefly in a few places, including a proposed cobble berm to mitigate this risk in the main report (Section 3.5.3.3, pp. 3-40 - 3-41, p. 7-1 and elsewhere). Additional analysis is appropriate given the consequences of breaching at this location. It is not clear what analysis has been conducted to evaluate the performance of the proposed dune augmentation. It is not known if the volume of material per linear foot is sufficient to provide the required width of cobble beach for stable conditions upon adjustment after initial placement. Maintenance requirements are not known for this design. Studies by DOGAMI (Allen, 2005) have been conducted on dynamic revetments for shoreline stabilization on the Oregon Coast but do not appear to have been applied. The breaching potential will likely increase with increasing shoreline erosion and loss of sediment from the system. However, potential beneficial use of dredged sediment is not analyzed as part of a design solution for a breach. Long-term erosion trends are assumed and are not adequately addressed in the report. The information provided is inconsistent in this area, with some sections saying the South Jetty dune erosion/augmentation issue will be addressed as part of a separate project, whereas other report sections include South Jetty dune augmentation as part of this project. Foreshore dune breaching has occurred at other coastal inlet navigation jetty structures along the Pacific Coast such as the South Jetty at Grays Harbor, Washington. Beach renourishment with dredged material and jetty structure modification improvements to prevent dune breaching were made with varying levels of success. It is not clear whether these similar project conditions and performance have been evaluated as part of the development and analysis of alternatives at the Columbia River South Jetty location.
Significance – High:
Breaching the dune at the South Jetty root appears to be a substantial risk, with more immediate consequences than breaching of a jetty because of the potential for forming a new tidal inlet with relatively rapid widening and deepening.
Recommendations for Resolution:
1. Either include the South Jetty dune augmentation/stabilization as part of the alternatives, and include costs and preliminary engineering, or state that it is not an element of the proposed work and is part of a separate project. Either way, potential breaching scenarios should be evaluated/modeled and included in the sediment transport and hydraulic analysis. This major investigation is the logical place to add studies of the MCR system (including jetties, navigation channel, estuary, and beaches). 2. Account for long-term shoreline erosion/recession trends in the design.

3. Review other jetty rehabilitation project solutions and performance at coastal inlet navigation facilities such as those conducted at the Grays Harbor South Jetty (Wamsley, 2006).

Comment 7:

The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.

Basis for Comment:

The document “design_criteria_info.doc” is vague. It discusses “50 year alternatives,” but the term is not defined. It could mean many things, including the following:

1. The project life is 50 years, with complete replacement assumed after 50 years.
2. Design jetty repairs that have the least life-cycle costs over a 50 year period.
3. The economic planning horizon, benefits and costs, are calculated for 50 years.
4. Design to withstand a series of storms over a 50 year period.
5. Design to withstand a single 50 year return period storm event.

Section 3.5.2.1 (Cross Section Intent and Design Philosophy) states, “The repair template must … allow the maximum repair within funding limitations.” This indicates the main design criterion is to provide the most repair possible within a budget limit, rather than design to withstand environmental loads and forces. The “funding limitations” are not stated, yet appear to be behind many of the design and planning decisions. Using funding limitations as a design criterion is not the same as an engineered design that meets environmental loading criteria. The funding limits design criteria are not consistent with the environmental loading design criteria in “design_criteria_info.doc.”

Note that a 50 year project life does not necessarily mean one should apply a 50 year return period event for the design environmental criteria. For example, a petroleum development platform may have only a 35 year project life, but the project may be designed to withstand a 100 year return period storm event or longer. The consequences of jetty failure should be considered in establishing the design criteria. ISO standards are sometimes applied in practice, but do not seem to be included in this work. Additionally, USACE (1995; paragraph 2-4) states rubblemound structures should be designed to successfully withstand the conditions that have a 50% probability of being exceeded during the project’s economic service life. The economic service life needs to first be established as a criterion and then the design storm formulated to meet the acceptable risk level for that service life.

A span of 50 years may be appropriate for an economic planning horizon; however, a 50 year project life or a 50 year return period storm event does not seem reasonable for engineering design considering the importance of navigation through the MCR. The structures should be designed to last indefinitely, as permanent structures, with regular maintenance requirements estimated and included in an economic analysis.

The 50 year criterion may not be consistent with parts of the report that mention a longer period of time. The SRB model discussion in Appendix A2, p. 78 states, “The period of analysis for future condition simulations was 64 years (2006 to 2070) for the North Jetty and Jetty A and 63 years (2007 to 2070) for South Jetty.”

Appendix A2 (p. A2-8) states, “The MCR jetties were constructed to achieve an expected service life of 50-100 years,” and concludes that 0.7% per year is the expected maintenance cost based on the 50-100 years service life. The 50-100 years service life, and associated 0.7% figure is used to inform the analysis and to demonstrate a lack of maintenance. However, the original 50-100 years service life, and 0.7% annual expected maintenance cost are arbitrary assumptions. The historic assumed service life and maintenance needs are not supported by the information presented, and largely irrelevant to today’s design and maintenance criteria.

The design criteria, if any, from 100 years ago when the jetties were built are not presented and previous maintenance are considered an operational cost. Analysis of past maintenance also may distract from the main problem afflicting the jetties: poor design 100 years ago, not deferred maintenance.

The original builders, working before the development of modern coastal engineering methods, underdesigned the jetties with only 7 ton armor rock, at their angle of repose of 1.25h:1v, or steeper. In addition, they constructed the immense structures on ever shifting sand shoals, locating them where the shoal happened to be at the time of construction, without adequate design features to account for shifting channels and currents.

The starting assumptions and criteria and alternatives are so narrowly constrained that there is questionable value in much of the analysis. The Major Rehabilitation Evaluation study is set up so that the end result is always the same; more rock within the existing jetty footprint. Conventional coastal engineering practice for a project of this scope would include the following:

1. Analysis to determine how much jetty is really needed today to maintain the navigation channel at reasonable cost. The Panel questions whether all 9+ miles of jetty are optimal. There has been no upward trend in maintenance dredging volumes since 1956, despite continued jetty tip recession, which indicates shorter jetty lengths would be equally functional at less cost.

2. Evaluation of alternatives that are not constrained to the original footprint, not built to the maximum crest elevation and authorized length feasible, not constrained only to rock, and discussed or considered beneficial use of dredged material as a design element.

3. Evaluation of durability issues and lessons learned from related projects. For example, the Dover Pier in England has lasted well over 100 years. Similarly, the Humboldt Bay jetties and Crescent City jetties in Northern California have effectively stopped jetty head recession using 40 ton dolos concrete armor units, and the Japanese are building breakwaters with 90 ton dolos concrete armor units.

Significance – High:

The lack of criteria prevents NED analysis and evaluation of whether the structure design meets standards.

Recommendations for Resolution:
1. Establish conventional project criteria including project life, standards of performance and function to be met, and environmental loads and return period events, which are part of conventional coastal engineering design practice. Document in a Preliminary Design Report. 2. Establish Design Environmental Conditions that have a specific return period. 3. If unable to meet the design criteria due to budget limits, state the budget limits as a criterion, and estimate what the equivalent design life or expected performance will be for the compromised design. 4. Expand the starting assumption to allow: a. Beneficial use of dredged material as a component of jetty rehab. b. A design outside the existing jetty footprint c. A design that may allow jetty head recession up to a point when maintenance dredging needs increase. d. A design that can include a partially submerged jetty cross-section. 5. Use a longer return period than 50 years for the design environmental criteria and consider ISO standards. 6. Consult with Dover Pier representatives and other jetty builders to discuss durability issues and lessons learned from their project in order to benefit the MCR project.

Comment 8:

The models and analyses of jetty failure do not include all significant processes.

Basis for Comment:

The SRB and STWAVE models cover many significant processes and variables that affect long-term jetty stability; however, some variables and processes are missing that should be presented in the SRB model and the Major Rehabilitation Evaluation Report:

- Armor rock breakage, rounding and wear, which can significantly affect jetty performance, do not appear to be included in the analysis.
- Deep seated slip surface failures through the jetty section, a global failure similar to a landslide, also do not appear to be analyzed and may be a significant risk.
- Wave height in combination with currents can cause significantly higher sediment transport rates than waves only or currents only. It is not clear if sediment transport analysis, considering both waves and currents acting together, has been done.
- Long-term changes in outlet channel morphology do not appear to be analyzed. The process of jetty decay through tidal channel scour appears different at Jetty A than at the North or South Jetties. Tidal channel scour at the tip of Jetty A will not be mitigated by adding spur groins, therefore a different system will need to be designed at Jetty A and accounted for in the jetty performance analysis.

The STWAVE model is not sufficient for modeling detailed wave transformations. Important processes such as wave structure interactions, refraction, and diffraction are incorporated in STWAVE using approximate methods. Other models like BOUSS-2D and CGWAVE are readily available and model the physics of these important processes more directly. STWAVE is appropriately applied as a regional wind-wave generation model for regions without a complex bathymetry. However, the Mouth of the Columbia River morphology near the jetties and navigation channel is complex. A phase-resolving wave transformation model such as BOUSS-2D or CGWAVE should be applied at this level of design in addition to STWAVE.

Significance – High:

The analysis of potential jetty failures, waves, currents, and sediment transport is incomplete for this level of design, and may result in significant errors in the evaluation of alternatives. Errors could include underestimating the design wave height, leading to undersized armor rock, excessive maintenance requirements and structure failure.

Recommendations for Resolution:

1. Estimate future repair needs and armor rock characteristics based on past performance of rock at the jetties. This requires a more detailed survey of existing condition, including quantifying existing armor rock size, gradation, and shape.
2. Analyze foundation stability based on measured geotechnical properties. A subsurface geotechnical investigation, including borings and soil testing, is recommended.
3. Provide a design concept for scour protection at Jetty A and check its stability against design environmental criteria, including specific current speed and wave height.

4. Apply models and use analysis methods to investigate sediment transport patterns and jetty foundation erosion under a combination of both waves and currents.
5. Supplement the STWAVE model with a wave transformation model such as BOUSS2D or CGWAVE to help determine design wave heights near the jetties.

Comment 9:
The alternative selection process may fail to meet the requirements of NEPA Section 1502.14.
Basis for Comment:
The design alternatives presented in the document are limited to the repair and rehabilitation of the jetties within the present configuration. The Panel is concerned about the adequacy of the alternatives analysis and the limited range of alternatives considered. NEPA Section 1502.14 requires a rigorous examination of all reasonable alternatives to any proposal and justification of eliminated design alternatives. The Panel finds that there is little examination of alternative approaches to the principal function of the MCR jetties, which is to secure a consistent navigation channel across the bar at the MCR. As such, the narrow scope of alternatives presented weakens this project. Insufficient information is provided to justify limiting the improvements to the existing footprint. For example, the report does not provide the technical basis for maintaining the 1895 jetty design, length, and orientation to the exclusion of considering other configurations. Considering reasonable alternatives, under NEPA guidance, would allow USACE to use hydrodynamic modeling tools to evaluate alternatives such as the use of weir jetties (Seaburgh, 2002) and other sediment management methods that facilitate bypassing sediment at coastal inlets, as well as low wave and high wave depositional basins in a manner which may reduce long term operation and maintenance costs. The impact of not considering additional alternatives leaves the overall justification of the project less defensible and may lead to questions of the overall merit of the rehabilitation project
Significance – Medium:
Consideration of alternatives beyond rehabilitating the original jetty structures within their existing footprint would comply with NEPA directives, and provide critical information that may reduce long-term costs and improve jetty life and efficacy.
Recommendations for Resolution:
1. Assess, and validate or reject, the technical basis for the initial jetty design, length, and orientation using appropriate physical coastal process models. 2. Assess structural efficacy and cost of alternatives which are not constrained by the existing footprint. 3. Develop modeling efforts for hydrodynamic models and/or sediment transport models that would provide insights into the following areas: a. Thorough analysis of the existing jetty structures focusing on why some areas have survived without repair and others have needed repeated repairs b. Examination of why Jetty A had such a large O&M cost relative to predictions. c. Addition of subsurface berms potentially created through the beneficial use of project dredged material that may reduce wave impact and subsequently reduce wave overtopping and toe scour.

Literature Cited:

Seaburgh, W. C. (2002). Weir Jetties at Coastal Inlets: Part 1, Functional Design Considerations. U.S. Army Corps of Engineers, ERDC/CHL CHETN-IV-53. December.

Comment 10:
A failure analysis for the original structure design and past trends of Operation and Maintenance (O&M) costs has not been provided.
Basis for Comment:
The extent of structure failure or partial failure is well documented and the repairs made to the structure are well documented, as shown in Figures 1-12, 1-15, and 1-16. These figures, however, do not distinguish between areas repaired and areas that are substandard but have not failed and so were not actually repaired. Failure analyses for the groin tips and the runnel formation weakening Jetty A (p. 3-5) are presented, but the report does not include a general failure analysis. A failure analysis would be helpful in determining why one section of jetty failed/degraded whereas another remained intact. This information is needed to derive alternatives that resist both degradation and failure, and result in an informed design of jetty repairs. Maintenance histories (Figures 1-21 through 1-23) show that actual O&M costs have trended significantly above and below the expected O&M costs, based on annual expenditures equivalent to 0.7% of the initial construction costs. Specific causes of actual O&M costs being higher or lower than the assumed 0.7% annual average cost have not been analyzed but can be presumed to be directly related to full or partial failure of portions of the structures. Knowledge of the specific causes of failure combined with the cost of constructing a jetty resistant to these causes taken in consideration of maintaining a jetty less resistant to these causes may be useful in determining or presenting the most cost effective alternative design. A specific presentation of individual jetty failure events would serve to bolster the alternative selection process and the projections of future maintenance costs.
Significance – Medium:
Uncertainty regarding the specific causes of failure and their relationship to trends of past O&M costs creates a functional uncertainty in the corrective measures in the alternatives for repair and rehabilitation.
Recommendations for Resolution:
1. Include an analysis of the causes of failure for each repair event (e.g., Figure 1-15) even if only a statement of "storm intensity" in order to provide assurance that the repairs address the actual causes of previous jetty failures. 2. Relate construction costs of more resistant designs to repair costs of less resistant designs for each causal condition of failure and the associated selected alternative.

Comment 11:
Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.
Basis for Comment:
The issue of climate change, sea level rise, and increased wave action is important to consider in the evaluation of long-term projects (USACE, 2009). There is no discussion in the main report of sea level rise and its impact on this project over the 50+ year project timeline. There is a limited discussion of climate change in Appendix D (p. 5), where the conclusion is that since the projected historical trend of sea level at the project site is estimated to be -0.05 feet in 50 years, sea level rise is not projected to be a significant climate change factor at the project site. Appendix D states the "comprehensive analysis of historical storm events is expected to adequately capture the present deep water contribution of potential wave height variation for this project site. The above approach forms the basis for estimating the potential changes in wave climate that could affect the MCR jetty system." However, this discussion on wave height trends is not compelling. The main report states (p. 1-6), "As the tidal shoals continue to recede (erode), the MCR jetties will be exposed to larger waves and more vigorous currents. To make matters worse, the regional wave climate along the Northwest Pacific Coast has become more severe in the last 10 years. The offshore 100-year wave height has been revised from 41 to 55 feet." (see also Appendix D). The main report states (p. 3-42), "The limit of cross-section resiliency is reached for jetties when the core stone becomes exposed to wave attack." Therefore, this issue may affect jetty erosion and a larger range of wave heights should be included in both the SRB and STWAVE model scenarios. Wave overtopping is central to the environment deteriorating the existing jetties. As the planning horizon of this project is 50+ years, it seems that a discussion would be useful of sea level rise and modeling potential wave heights and the wave overtopping impacts on the jetties given different rates of recession under a wider range of wave heights. Jetty height and crest elevation are variables that should be modeled given the potential larger wave heights possible under sea level rise. Although the selection of the recommended plan may not change, long-term maintenance costs may be affected, therefore consideration is warranted. Appendix B states that transient internal hydraulic effects of wave impact may be the most important parameter in the stability of the jetties. However, it is the least certain of all of the parameters. Internal hydraulic pressures in jetties have not been measured. Given this, it seems especially important to consider more extreme wave heights beyond the wave height analyzed, with respect to sea level rise and potential increasing wave height.
Significance – Medium:
The discussion of potential impacts of sea level rise and increased wave action on jetty structures is critical to understanding the potential impacts to the project and in designing a project with lower long-term maintenance costs.

Recommendations for Resolution:
1. Add a separate section to the Major Rehabilitation Evaluation Report that examines climate change, sea level rise, potential wave height changes, and resulting wave overtopping impacts on the jetties given different rates of recession under different model scenarios.

Literature Cited:

USACE (2009). Water Resource Policies and Authorities Incorporating Sea-Level Change Considerations in Civil Works Programs. Department of the Army, U.S. Army Corps of Engineers, Washington, D.C. Engineer Pamphlet EC 1165-2-211. 1 July.

Comment 12:

Construction cost estimates cannot be evaluated because the assumptions and details have not been provided.

Basis for Comment:

A detailed construction cost estimate summary should be provided for the recommended plan, otherwise the basis for the total cost values provided in Section 6.5.9 cannot be reviewed and assessed to determine if they are realistic and complete. The cost estimate information provided in the main report (Section 6.0) and in Appendix E is not sufficient to support the recommended plan:

- Table 6-3 provides a detailed summary of stone volumes for each jetty by construction year, but there is no correlation with construction costs or to the cost estimates provided in Section 6.5.9 or Appendix E.
- Specific cost estimating details are provided in Sections 6.5.7 and 6.5.8, but the assumptions and criteria defining the basis for the cost estimates do not include any summary unit costs for the individual work items.
- Unit costs are provided in Tables A2-9 to A2-11 but pertain to the SRB modeling effort. There is no discussion regarding how they relate to the final project costs presented in Section 6.5.9.
- Appendix E includes budget summary costs for construction, planning/engineering, construction management, and land acquisition. Detailed cost estimates for the Civil Works construction budget numbers are not provided and the basis for the costs cannot be reviewed or verified.
- Costs for the barge offloading and material re-handling area facility installation and maintenance are not described, yet they could be a large direct and indirect cost to the project based on wave exposure (for type and size of barge offload facility structures). The structural requirements (and corresponding construction costs) for an exposed vessel berth will be many orders of magnitude larger than the same berth in protected waters. Stone delivery cost represents a very large percentage of the total cost. Ensuring a cost feasible method of delivery to the jetty structures is critical for development of an accurate cost estimate.

Significance – Medium:

Detailed construction cost estimates need to be provided in order for the cost analysis to be complete and verifiable.

Recommendations for Resolution:

1. Provide a detailed cost breakdown by work item for the Civil Works project item, Breakwater & Seawalls. Provide detailed cost estimates for each major element of work (e.g., mobilization, stone supply and install, site preparation, material re-handling facility installation, maintenance of re-handling facilities, etc.). Give details regarding work item quantity, unit costs, contingency, and escalation.

2. Provide a detailed cost summary within Appendix E, and an additional detailed description of the basis for the costs estimates in Section 6.
3. Conduct an additional investigation of re-handling facility requirements to adequately determine the costs for facility installation and maintenance.

Comment 13:
Potential environmental impacts on sensitive species, upland habitats, and water quality have not been thoroughly discussed or specifically mitigated in the document.
Basis for Comment:
Appendix D and main report (pp. 5-17--5-20) list potential in-water, wetland, and upland impacts. These impacts should be addressed in the mitigation plan. The mitigation plans currently address these three general categories, but do not provide mitigation for potential impacts to specific species, upland habitats and water quality. The mitigation plans are incomplete because the final wetland delineation for the project has not been conducted, and the impact to wetlands and upland habitat is uncertain and therefore not quantified. A vegetation restoration plan is needed to address potential impacts to upland habitats, especially the rare and vulnerable species discussed below. At a minimum, the mitigation plan should state that these plans will be prepared prior to construction activities. Although the extent of the upland impact on this habitat is uncertain, a replanting contingency plan and a clear plan for avoidance are important to include in the mitigation plan. Similarly, potential water quality impacts from spills should be addressed in the mitigation plan with a statement about the spill prevention plan, as discussed below. Section 5.1 (Environmental Effects) of the main report provides details on biological resources, but is missing a vegetation section. Appendix D contains two reports including the Wetland and Waters of the U.S. Delineation Report and The Plant Communities Investigation Report, April 2007, which provides details on the vegetation communities; however, this information is not presented in the main report and therefore the main report lacks a definition of the plant species of concern within the project area. The revised EA states (p. 6) that at least three of these vegetative communities (shorepine-slough sedge, shorepine-Douglas fir, and coast willow-slough sedge) "have been ranked globally and by the State for their rarity and vulnerability to extinction and should be protected from impacts." This information on sensitive species should be integrated into Section 5.1. Furthermore, potential land construction activities as shown on Figure 5-1 of the main report may affect plant communities, including sensitive habitats, warranting a discussion of existing vegetation in the project area. Vegetation impacts that may result from construction are not detailed in the document, and just briefly mentioned in regards to the South Jetty. Mitigation plans should include specific protective measures to avoid potential impacts to these rare and vulnerable species. In general, the main report discusses Endangered Species Act (ESA) species, but does not provide detailed data on specific animal or plant populations. In 2005, critical habitat was designated for all Columbia River steelhead and Columbia River salmon evolutionarily significant units (ESU), with the exception of lower Columbia River coho salmon ESU. Although a wide range of potential impacts are discussed (p. 5-16), ranging from loss of habitat to an increase in perching and in-water habitat for predators that prey on listed species, the mitigation section of the Major Rehabilitation Evaluation Report does not address these impacts. The main report concludes (pp. 5-19 – 5-20) that there will be overall benefits to these species from this project. Additional details would be helpful to ensure that these species suffer no impacts. The Panel realizes that as a specific mitigation plan is developed, this may

likely be incorporated.

Water quality may also be affected over the project duration due to the large volume of container ships, construction dredges, barges, and cruise ships operating in the area, sometimes in adverse extreme weather conditions. For example, there may be a loss of hydraulic fluid or oil spills (p. 3-70). In the discussion of the mitigation plan in Section 5.4 (p. 5-17), the increased risk of pollutant release and spill potential is raised as a potential impact on ecosystem function. A sentence earlier in the document (p. 5-2) states that the Contractor "will provide a spill prevention plan to include measures to minimize the potential for spills and to respond quickly should spills occur." This sentence belongs in Section 5.4 of the main report as well.

Any history of spills in the Mouth of Columbia River area should also be reported in the document. Providing these details will enable a more thorough analysis of environmental impacts and enable additional protective actions to be implemented.

Significance – Medium:

Additional biological resources data and potential impacts to sensitive species, upland communities and water quality is needed to adequately protect the environment and define the mitigation needed to reduce these impacts to less than significant.

Recommendations for Resolution:

1. Incorporate additional information into Section 5 of the report:
   a. A vegetation section defining the sensitive species within project area.
   b. A statement to ensure that stockpiling activities shown in Figures 5.1 – 5.3 of the main report minimize the land impacts to sensitive habitats and wetlands. State whether a survey will be conducted prior to construction activities with sensitive habitats flagged to ensure avoidance.
   c. Provide detailed data on specific animal or plant populations that are listed species
   d. Specific text in the mitigation section for potential impacts to steelhead and salmon.
2. Add the wording from p. 5-2 into Section 5.4 of the mitigation plan regarding the contractor's requirement to prepare a spill prevention plan to address potential water quality impacts. Document any known history of spills in the area.

Comment 14:
Potential impacts to recreational use during project construction, as identified in public comments, are not adequately discussed or mitigated.
Basis for Comment:
The Major Rehabilitation Evaluation Report does not provide detail on the impact of the project construction activities on recreational use, an issue that came up in public comment letters (main report, Section 5.4). The last sentence in Section 5.3 states that there will be no significant impacts on recreation. Appendix C states that there is a growing cruise ship industry and it is unclear how construction activities will affect passenger cruise ship access. On p. C-3 it states that 5/7 day cruise ship tours carry 15,000 passengers annually, and thousands of tour boat passengers take day trips and dinner cruises. These activities generate about $15 to $20 million in revenue annually for local economies. Public access during construction may be an issue. In addition, other recreational uses of the area may be reduced, such as kayaking and hiking. These impacts should be defined, rather than concluding that no recreational or economic impacts to tourism are expected. Omitting this issue may lead to unforeseen consequences for the cruise ship and tourism industries.
Significance – Medium:
Recreational impacts are not adequately presented in the report and subsequently, no mitigation is identified for this potential impact.
Recommendations for Resolution:
1. Add a discussion of the cruise ship industry and other recreational uses at the project site. 2. Examine potential impacts on cruise ships and other recreational activities that may result from the dredging operations and jetty repair operations. 3. Provide potential mitigation options to reduce recreational impacts to less than significant levels. 4. Make a distinction between recreational impacts during construction and after construction.

Comment 15:
There is not sufficient information on the evaluation of barge offloading and material re-handling facilities to ensure these sites can operate as intended and to ensure the construction costs are adequately represented.
Basis for Comment:
Contract-provided barge offloading facilities for the South and North Jetties are described in Sections 6.3.3 and 6.3.4 and shown in Figures 5-1 and 5-3 of the main report. Based on the information presented, it is not clear that these sites have been adequately investigated and are suited for their intended use. The barge offloading and material re-handling facilities at these outer exposed locations should be further investigated to ensure they are economically and operationally feasible. The proposed facilities are referred to as "temporary," but this is questionable if they will be in place for 20 years. The life-cycle costs of the docks and other structures are not trivial and do not seem adequately analyzed. The largest cost and a substantial risk for the recommended plan involves the purchase, transportation, delivery, and offloading of the stone in a very difficult environment over a relatively long time. The USACE-provided sites also need to be operationally feasible in order to use a permitted method of delivering material to the site. Providing contractors with better information on the limitations and usability of these sites at the time of bidding could result in substantial cost savings. There is no discussion in the report of any engineering work performed to evaluate the feasibility of installing structures at these exposed locations, nor any mention of operational feasibility for the size of vessels and wave climate for the periods of construction. These locations are subject to wave heights of more than 15 feet, which will impose very large wave impact loads on fixed structures (dolphins and sheet pile walls), resulting in high risk and cost facilities. USACE intends to permit these sites and provide them to the contractor as the primary point of access. This establishes a certain level of perceived usability to bidders. If they are later determined not to be feasible (i.e., during contract bidding or during construction), it would result in substantial cost and schedule changes. Use of the re-handling facilities will be limited to a "summer" work period (April to October). There is no analysis of sedimentation rate in the report to verify whether the floatation channels will remain open for the summer construction work period. Maintenance dredging estimates for barge offloading facilities are provided in Table 6-1, but it is not clear for what time period (annually or total over the entire duration of the project). Jetty A is listed at 80,000 cubic yards for maintenance dredging. Other options, such as dredging within the Ilwaco channel to the trunk end of Jetty A and developing an offloading facility adjacent to the staging area could be considered.
Significance – Medium:
Insufficient information on the limitations and usability of the offloading and re-handling sites could affect construction cost estimates and project schedule due to operational and physical environment constraints.

Recommendations for Resolution:
1. Conduct a feasibility level engineering analysis and design for the contract-provided offloading and rehandling sites to ensure that selected sites and facilities are feasible and provide reliable estimates of construction cost. The feasibility evaluation should at a minimum include the following: a. Evaluate feasibility of constructing pile supported structures within an extreme hydrodynamic environment. This includes wave/current loads on moored vessels during the construction period and wave/current loads berth structures during extreme winter conditions. b. Evaluate downtime of barges at the proposed sites relative to the wave and current climate during the proposed construction work period. c. Refine the type of structure that is feasible for these locations for inclusion into project permits and cost estimates. 2. Evaluate the need for alternative barge offloading and material re-handling site locations based on the results of the feasibility analysis. 3. Evaluate design concepts for permanent barge/dock facilities, possibly incorporated into the inside face of the jetties near their root. 4. Develop environmental data specific to the proposed offloading site locations for bidders/contractors to use in developing their estimates of downtime and infrastructure requirements at USACE provided rehandling sites. Extreme event offshore wave data and jetty structure design criteria will not be sufficient for contractors to use in evaluating short-term operational and design requirements.

Comment 16:
The requirements, costs, and history associated with emergency dredging compared to scheduled maintenance dredging activities have not been specified.
Basis for Comment:
Dredging is a substantial component of this project and has been historically, yet there is no clear discussion of the role of dredging in the Major Rehabilitation Evaluation Report. Typical annual dredging rates are not presented in the document itself, although Appendix A1 (p. A1-3) states, “Each year, the Portland District dredges 3 to 5 million cubic yards (MCY) of sand at MCR to maintain the 5-mile long deep draft navigation channel.” It is unclear if the Portland District dredging is conducted exclusively at MOCR. Analysis of the project area maintenance dredging requirements – past, present, and future – have not been presented. Controlling dredging costs is critical to this project. The EPA publishes a report annually analyzing dredged sediment disposal in the nation. About 4 million cubic yards is dredged at the MCR every year at an annual cost of about $10 million. The fact that maintenance dredging volumes in the project area have not increased (no clear trend) since 1956, despite ongoing jetty tip recession, raises the question of how much jetty is now needed to maintain the MCR navigation channel. However, the main report does not discuss details of the maintenance dredging. Appendix B states the geological history includes 225 million cubic yards of dredging from the MCR navigation channel since 1956. The volumes, history, and fate of these dredged sediment volumes should be described in the main report and are missing from the analysis. The fact that most of this sediment was dumped far offshore and lost to the nearshore may have something to do with the erosion experienced in the area. This large quantity of dredged material warrants discussion and additional consideration of strategies to reduce this volume. The discussion of emergency dredging is also lacking in the main report. The historical downtime for dredging at the dock and jetty repair work during the time period of October to March (peak period for large waves) is not provided. Page 3-70 states, “Given the winter wave conditions that the dredges would be performing in, it is highly likely that damage would occur to the drag arm of the dredge while working.” Page A2-65 states that within the SRB model “there is a 0.3 probability that one dredge will lose a drag-arm while performing dredging during winter or a 0.7 probability that one dredge would realize equipment damage,” thereby increasing dredging costs. Several places reference the difficulty of dredging in the winter. Conditions may preclude effective dredge use, or the dredge may break and become inoperable, suggesting dredging may be postponed until summer. In terms of dredge operation, p. 1-48 gives the operational limitations of hopper dredges, and admits that operating a hopper dredge at the MRC during winter months has not yet been attempted. Therefore, the inadequate demonstration of equipment effectiveness, lack of documentation of the basis of dredge damage probabilities, and lack of historic utilization increases the risk associated with estimating costs associated with emergency dredging. The document states on p.1-50 that the rate of shoaling within the MCR channel would not be high enough to require emergency dredging; therefore, the increased shoaling volume could be dredged the following summer and would not be considered emergency dredging. The

document never presents operational triggers for when emergency dredging would occur.

The main report indicates that there are four dredges capable of working in winter (p. 3-111), but these dredges are not mentioned earlier, when it was presented that only one or two dredges are available in the short term. A discussion of emergency dredging history, success in other areas, and a description of the equipment available is warranted.

The analysis considers long-term O&M costs of dredging, but does not explain the criteria used in the calculation estimates.

There is no mention of any historic environmental impacts from the dredge operations, such as spills. If spills have occurred, data should be presented.

Significance – Medium:

Additional information on dredging may enable better analysis and lead to a long-term reduction in dredging costs and the development of a contingency plan to successfully avoid navigation impacts.

Recommendations for Resolution:

1. Develop a paragraph on dredging in the main report that specifies clearly what the maintenance dredging program has been, rates, and frequencies, and if they are scheduled or "as needed." Present all the historic maintenance costs, schedules, and frequencies.
2. Provide a detailed history of emergency dredging with success and failures and costs.
3. Add information to specify what rate of shoaling requires emergency dredging compared to scheduling maintenance dredging activities.
4. Present the criteria used in the calculations of dredging O&M costs.
5. Provide any information on historic spills related to dredging operations.

Comment 17:
The current jetty structure condition is not well described, making it difficult to confirm the confidence of the SRB model analysis and selection of a recommended plan.
Basis for Comment:
Although there is a good description of historical failures and repair actions for each jetty, there is no discussion or documentation of current jetty condition or detailed condition assessments of structure and functional condition. A condition assessment of each jetty structure should be conducted through a combination of visual inspection (stone size, gradation, slope defects, stone defects, loss of armor stone, core exposure, etc.) and evaluation and comparison of historical electronic surveying results (single beam, multi-beam, or side scan sonar data). These elements will provide the basis for determining the present condition, assess risk of current condition to failure, and help classify structure along various reaches of each jetty. These data would enable better assessment of vulnerabilities, analyzing why some areas in the jetty have maintained without repair and other areas have needed multiple repairs. A better understanding of these dynamics may reduce O&M costs over the long term. Rubble-mound structures have a tolerance for deterioration before suffering catastrophic failure. A thorough understanding of current and historical structure condition is critical to developing an estimate of the mechanisms causing failure, establishing the timeframe for catastrophic failure, and conducting maintenance/repair work. The SRB model evaluation of alternatives using the base condition depends upon an adequate understanding of current jetty conditions and corresponding impact on estimated future repair and maintenance. The current SRB analysis is based on a "hindcasting" of jetty performance relative to historical performance, but without consideration of the details of condition and causes of failure. The current and historical condition relative to structural and functional rating should be conducted following USACE procedures (USACE, 1998) to establish the baseline conditions for the SRB model analysis. Evaluation of stone source and quality relative to length of service on the structure should be conducted as part of the jetty condition assessment.
Significance – Medium:
A detailed description of the current jetty structure as part of a condition assessment is necessary to understand the accuracy of the SRB model.
Recommendations for Resolution:
1. Conduct a detailed condition assessment of each jetty structure, including visual inspection and historical survey comparison. 2. Compare historical survey data for the validation of interpreted historical conditions and corresponding perceived modes of failure. Incorporate results into the development of baseline conditions for the SRB model. 3. Use a condition rating system such as that outlined in the USACE Manual REMR-OM-24 (USACE, 1998) for evaluation of current condition. Assess both the structural and functional condition of the structures and incorporate the results into the SRB model analysis.

4. Incorporate the results of the condition assessment into Section 1.4, description of project history.
5. Provide an additional description of existing condition in Section 1.4 and 3.3.2 of the main report, including the service life of stone sources used for previous repair and maintenance activities.
6. Based on the results of the condition assessment, the relation between the stone sources reviewed (in Appendix B, Section 5) and the corresponding observed service life of that stone should be discussed and incorporated in the SRB analysis.

Literature Cited:

Comment 18:

The mechanisms causing jetty head scour have not been sufficiently analyzed to allow selection of the appropriate jetty head repair measure.

Basis for Comment:

Causes of jetty head scour have not been sufficiently investigated. Tidal shoal and outlet channel geomorphic processes should be further evaluated and analyzed to ensure that proper jetty head repair measures are selected. The mechanisms causing the "scour holes" and undermining of the jetty in the vicinity of the jetty tips (North Jetty and Jetty A) have not been sufficiently analyzed for selection of the jetty head repair measure. Figure A1-32 indicates a progressive erosion of ebb tidal shoals in the vicinity of the North Jetty (between Stations 60 and 90) undermining the south toe of the structure.

The report understates the situation when it notes (Appendix A1, p. 28), "If the jetty foundation washes away, jetty reconstruction is problematic." A solid understanding of the environment and bathymetry changes is essential for development of a reliable design alternative.

Spur groins installed along the south slope of the North Jetty will assist in addressing scour generated by localized currents, but will not provide protection from overall MCR tidal shoal and channel morphological changes. Continued ebb shoal erosion and potential tidal channel movement could undermine the head of the proposed offshore spur groins (located near Stations 90 and 70).

It seems likely that scour holes are related to the observed jetty tip recession. The 100 foot deep scour hole at the end of Jetty A is particularly alarming from a structural design perspective. Equally alarming is the discussion of "Vertical scour along the toe of the MCR jetties has exceeded 10 meters in some reaches" (Appendix A2, p. A2-11). If there really is, or was, a more than 30 foot high underwater scarp in places along the toe of the jetties, then more investigation is warranted.

Figures showing typical sections often do not extend to the toe of slope, and show details that aren't feasible, such as rock limits ending in a small angle without an engineered toe. (See Appendix A1, Figure A1-258).

Strategies to deal with scour, especially at the jetty tips appear undeveloped. Design features could include scour blankets, launched toes, or a program of regular fill using dredged material.

Significance – Medium:

Inadequate evaluation of the geomorphic processes responsible for the deterioration at the jetty tips (North Jetty and Jetty A) could lead to an incorrect approach to rehabilitation of those areas of damaged structures.

Recommendations for Resolution:

1. Conduct a more detailed evaluation of historical geomorphic changes in the outlet channel and shoals in order to evaluate tidal shoal erosion and tidal channel migration. Comparative analysis of historical bathymetric surveys would be helpful in developing a better understanding of historical trends and associated correlation with jetty structure historical damage, failure, and repair activities. Additionally, use historical geomorphic change analysis and hydrodynamic analysis to estimate long- term changes and impacts to the North Jetty and Jetty A to formulate jetty head rehabilitation alternatives and development of design criteria.
2. Do not limit the jetty repair preliminary designs to the footprint of the authorized jetties. Evaluate scour protection alternatives extending past the jetty tips.
3. Draft plans, profiles, and sections at this level of design using suitable software, such as AutoCAD® or MicroStation®. Microsoft Excel® is not an adequate substitute for drafting software.
4. Draft the jetty design typical sections to scale and extend past the scour holes and navigation channel.
5. Conduct a subsurface geotechnical investigation to obtain the geological properties needed to verify or design an adequate foundation.

Comment 19:
Risk thresholds for selected alternatives are not clearly defined.
Basis for Comment:
Risk thresholds are used in repair frequency predictions as triggers for maintenance response and subsequently in maintenance cost predictions. The frequency of reaching degradation thresholds is predicted by risk thresholds. Combining degradation thresholds with repair costs (minor vs. major) can also be used to determine the threshold for triggering maintenance actions, balancing multiple small repairs against the cost of a single major repair. The Major Rehabilitation Evaluation Report includes extensive discussions of risks related to different portions of the project; however, while this discussion of risk is extensive, defined thresholds are not presented in the document. It is to be expected that the risk (probability) of surpassing thresholds may vary among alternatives in both configuration (number and placement of spurs, jetty length) and in cross sections considered. The risk associated with each alternative considered should be assessed based on materials, cross sections, supporting geological features, currents, and storms. It is also proper procedure to examine how the risk of one design component may be altered by the inclusion or exclusion of a second design component.
Significance – Medium:
Undefined risk thresholds may serve to undermine the logic of the cost and maintenance predictions and, to a lesser extent, the alternatives selected.
Recommendations for Resolution:
1. Define risk thresholds for alternatives, including source of risk and effect of exceeding the threshold.

Comment 20:
It is not clear how uncertainty and derived risk analyses were considered in the structure and application of the model.
Basis for Comment:
Project life-cycle cost analyses should consider the risk of construction cycle and operational cycle downtime, which does not appear to be included. However, risks cannot be evaluated without understanding the level of uncertainty associated with the SRB model result. The uncertainty associated with actual future conditions, which may deviate from the modeled future conditions, is not apparent. The SRB model includes 600 variables (Section 9, p. A2-91) each of which has a data set which can be expected to reflect an associated variance. Depending on the calculation stream, these variances, applied geometrically, will lead to accumulated statistical errors and uncertainties. These cumulative internal variances can be expected to result in high uncertainty in the output of the SRB model, which should be considered in the evaluation of alternatives.
Significance – Medium:
Potentially wide error bars (uncertainty) may compromise life-cycle maintenance and repair schedules.
Recommendations for Resolution:
1. Quantify and explain the uncertainty (i.e., error bars) associated with each variable when analyzing processes that involve a chain of events. 2. Identify, analyze, and define errors that may accumulate to assess model reliability.

Comment 21:

The model output parameters and wave height components are not clearly explained and supported.

Basis for Comment:

The meaning of the following SRB model output parameters is not clear:

- Functional Reliability
- Structural Reliability
- Probability of Unsatisfactory Structure Performance.

For example, the main report (Section 3.6.1, p. 3-43) includes the following: "Functional reliability is the likelihood that a structure will satisfactorily perform its intended function within a given time interval. Functional reliability is derived by combining structural reliability metrics with metrics that describe the present structure cross-section configuration." One difficulty is that the understanding of "Functional Reliability" requires first understanding "structural reliability metrics", (which are not to be confused with "metrics that describe the present cross-section configuration"). However, the "structural reliability metrics" are not clearly defined either. A word search of Appendix A2 for the term "Structural Reliability" does not reveal a set of equations for calculating the parameter or a clear explanation.

Similarly, much of the SRB model includes terminology and variables that are hard to understand. For example, Table A2-12, Jetty Maintenance Thresholds, (p. A-60) consists of numbers and parameters not connected to anything that has a physical meaning. Conventional calculations and metrics such as volumes, areas, and depths are parameters with physical meaning that would improve the understanding of the SRB model. Understanding the SRB model outputs would be improved with graphics that are connected to parameters with physical meaning.

The wave height component of the SRB model is not supported by standard coastal engineering practice. Progressive jetty damage in the SRB model is based on a stochastic time series of wave heights, which is derived from "An ensemble of 52 storm events … recorded at NDBC buoys… during 1998 to 2008." It is unclear why only 10 years of buoy data were used when a longer record of more than 17 years with gaps removed is available (Appendix A1, pp. 34 and 37). It is also not certain that extreme wave height events were properly included in the SRB model process. It is common industry practice to test a coastal engineering design using a specific design environmental criterion, such as the 100 year return period wave height.

Significance – Medium:

The model parameters that compare alternatives lack a physical meaning, such as a volume of rock or depth of scour. It is therefore difficult to verify, calculate, or evaluate whether the parameters used or model results are reasonable.

Recommendations for Resolution:
1. Explain and demonstrate how the model output parameters relate to physical performance measures, with graphics or figures. 2. Measure jetty damage and performance with conventional calculations, and commonly applied metrics, for example: a. Volume of sediment entering the navigation channel, or dredge volume, b. Depth or volume of scour at the jetty toe c. Volume or area of armor rock displaced from the jetty. 3. Test the design against a specific storm event, such as the 100 year return period event. 4. Calculate the return period of extreme events using the complete record of measured offshore wave data.

Comment 22:

The culvert installation details, as well as potential impacts, need further clarification.

Basis for Comment:

The Major Rehabilitation Evaluation Report states that the existing culvert has increased scour and adversely affected the North Jetty, and that it will be relocated. There are a few sentences in the main report and in Appendix D that mention the culvert, but there is not enough information provided in the main report to determine if there will be any potential impacts from the new discharge location. The table at the end of Appendix D provides the most detail anywhere in this report regarding the culvert relocation. On p. 6-6 in the main report there is a sentence stating work will begin in 2014 to install a culvert to divert overland flow to another area that will not impact the North Jetty root stability. While this sounds like a reasonable approach to protect the North Jetty, more information is needed to clarify the impact such as the source of the water, an assessment of the water quality, and an estimate of the flow rate involved. Without knowing the exact new location, it is not possible to assess the potential environmental impact of relocating this water flow.

Significance – Medium:

More detailed information on the new location of the culvert as well as water quality, flow rates, and source of the water is necessary to determine the environmental impact of the relocation.

Recommendations for Resolution:

1. Add one paragraph in the main report that addresses the culvert relocation.
2. Present any available data on the water quality, flow rates, and water source of water discharged through the culvert.
3. Provide the specific location planned for new culvert.

Comment 23:
The various base years cited in the report and the difference between project life and period of analysis require additional explanation.
Basis for Comment:
The terms “project life” and “period of analysis” are not defined or differentiated, and the project base year varies throughout the report: • In the economic spreadsheet models, the NPVs are calculated for differing periods of analysis (2009-2070 for South Jetty, 2008-2070 for Jetty A, and 2008-2070, 2008-2057 and 2008-2069 for the North Jetty); whereas the AACs are based on a 50 year period of analysis. • The period of analysis extends 50 years beyond the base year of 2011 when discussing sea level rise (pp. A1-38 and A2-68). • The period of analysis for future condition simulations is 64 years (2006 to 2970) for the North Jetty and Jetty A and 63 years (2007 to 2070) for the South Jetty (p. A2-78). • The AAC is calculated using an amortization factor applied to the present year cost stream from the NPV implementation year (2006/2007) to 2069 (p. A2-51). • The base year of the economic analysis is not identified in Section 2 or Appendix C, but is stated as 2014 elsewhere in the report (pp. ES-3 and A2-78). • Within the SRB model, the base year is stated as 2011 when discussing sea level rise (pp. A1-38 and A2-68). • Within the SRB model, the base year for NPV cost discounting is 2006 for the North Jetty and Jetty A, and 2007 for the South Jetty (p. A2-51).
Significance – Low:
Inconsistencies in terminology and periods of analysis can lead to misunderstanding of findings and results.
Recommendations for Resolution:
1. Define and differentiate between the terms “project life” and “period of analysis.” 2. Revise the report to eliminate inconsistencies between the varying periods of analysis. 3. Use a consistent base year throughout the analysis, and revise the report to reflect consistency. 4. Revise Section 2 and Appendix C of the report to state the year that is considered to be the base year, the length of the period of analysis, and the calendar years that are included in the period of analysis. 5. Provide definitions of all terms in a Glossary.

Comment 24:
Cargo tonnage and vessel trip statistics presented throughout the report are inconsistent.
Basis for Comment:
Data presented throughout the report have inconsistencies that should be corrected. The following are examples of inconsistencies in values for cargo tonnages, vessel trips, and value of cargo: • Page ES-1 – cargo on the MCR is 45 million (M) tons and 3,500 vessel crossings based on 2008 Waterborne Commerce Statistics Center data. These data are not cited in the body of the report. • Page 1-2 – cargo on the MCR is 40 M tons worth $17 billion, with 12,000 commercial vessels navigating the MCR annually. • Pages 2-1 and C-1 – cargo on the MCR is 40 M tons valued at $17 billion based on a 2009 Pacific Northwest Waterways Association (PNWA) factsheet cited in Appendix C. • Pages 1-4 and C-4 – cargo on the MCR is 32 M tons in 2003 and projected at 43 M tons in 2020 based on 2005 Center for Economic Development and Research (CEDER) data, cited as a footnote in Appendix C. • Page C-5, Table C-1 – 5,364 total vessel trips on the MCR based on 2005 Waterborne Commerce Statistics Center data. • Page A1-3 – cargo on the MCR is 48 M tons worth $16 billion, with 12,000 commercial vessels navigating the MCR annually. The cargo and vessel trip statistics presented in the report appear to include all traffic on the MCR and Lower Columbia River (LCR). The report assumes all traffic accessing the MCR is dependent on the MCR jetties. The without-project condition channel depths are not adequately described. The cargo and vessel trips that would be impacted by the jetties, that is, the portion of the fleet transiting the MCR that would be restricted by the without-project condition channel depths, is not described.
Significance – Low:
Consistent cargo and vessel trip data for the MCR are needed in order to develop an understanding of the significance of the jetties.
Recommendations for Resolution:
1. Describe the cargo tonnages, vessel trips, and value of cargo consistently throughout the report, or supply an explanation of the differences and why various data sources were used. 2. Describe the portion of the fleet accessing the MCR that is dependent on the jetties (i.e., what are the without-project condition channel depths and what portion of the fleet transiting the MCR would be restricted by the without-project condition channel depths).

Comment 25:

Terminology related to jetty rehabilitation and failure is defined inconsistently or vaguely in some places.

Basis for Comment:

Inconsistencies in terminology can make understanding the project difficult. Commonly used terms in the document, such as “failure,” are not clearly and qualitatively defined. Phrases such as “close to failure” appear frequently, in a qualitative sense, but without an understanding of how much jetty damage, if any, constitutes a “failure.”

Another example is in the SRB model where “fix-as-fails” repairs are described as, “To defer jetty maintenance for as long as possible, the jetty is maintained close to the margin of functional loss.” The concept makes sense but how the model deals with terms like “as long as possible” and “close to the margin of functional loss” is unclear.

Other phrases, such as “scheduled repair” and “rehabilitation” seem to be inconsistent as well. For example, “scheduled repair” includes “head capping” in the executive summary of the main report, but does not include “head capping” in some alternatives analyzed by the SRB model.

Significance – Low:

Without clear, consistent definitions of terminology, it is difficult to understand exactly what is being proposed or analyzed and can lead to misinterpretations.

Recommendations for Resolution:

1. Add a Definitions list or Glossary to the document.

This page intentionally left blank

APPENDIX B

Final Charge to the Independent External Peer Review Panel
as
Developed by USACE and Submitted to the Panel on December 28, 2010

on the

Mouth of Columbia River IEPR

This page is intentionally left blank.

CHARGE FOR PEER REVIEW

Members of this IEPR Panel are asked to determine whether the technical approach and scientific rationale presented in the Columbia River at the Mouth, Oregon and Washington Major Rehabilitation Evaluation Report are credible and whether the conclusions are valid. The Panel is asked to determine whether the technical work is adequate, competently performed, properly documented, satisfies established quality requirements, and yields scientifically credible conclusions. The Panel is being asked to provide feedback on the economic, engineering, environmental, geomorphology, and plan formulation. The panel members are not being asked whether they would have conducted the work in a similar manner.

Specific questions for the Panel (by report section or Appendix) are included in the general charge guidance, which is provided below.

General Charge Guidance

Please answer the scientific and technical questions listed below and conduct a broad overview of the Mouth of the Columbia River ER. Please focus on your areas of expertise and technical knowledge. Even though there are some sections with no questions associated with them, that does not mean that you cannot comment on them. Please feel free to make any relevant and appropriate comment on any of the sections and appendices you were asked to review. In addition, please note the following guidance. Note that the Panel will be asked to provide an overall statement related to 2 and 3 below per USACE guidance (EC 1165-2-209; Appendix D).

1. Your response to the charge questions should not be limited to a “yes” or “no.” Please provide complete answers to fully explain your response.
2. Assess the adequacy and acceptability of the economic and environmental assumptions and projections, project evaluation data, and any biological opinions of the project study.
3. Assess the adequacy and acceptability of the economic analyses, environmental analyses, engineering analyses, formulation of alternative plans, methods for integrating risk and uncertainty, and models used in evaluation of economic or environmental impacts of the proposed project.
4. If appropriate, offer opinions as to whether there are sufficient analyses upon which to base a recommendation.
5. Identify, explain, and comment upon assumptions that underlie all the analyses, as well as evaluate the soundness of models, surveys, investigations, and methods.
6. Evaluate whether the interpretations of analysis and the conclusions based on analysis are reasonable
7. Please focus the review on assumptions, data, methods, and models.

Please **do not** make recommendations on whether a particular alternative should be implemented, or whether you would have conducted the work in a similar manner. Also please **do not** comment on or make recommendations on policy issues and decision making.

Comments should be provided based on your professional judgment, **not** the legality of the document.

1. If desired, panel members can contact one another. However, panel members **should not** contact anyone who is or was involved in the project, prepared the subject documents, or was part of the USACE Independent Technical Review.
2. Please contact the Battelle Deputy Project Manager (Richard Uhler, uhlerr@battelle.org) or Project Manager (Karen Johnson-Young, johnson-youngk@battelle.org) for requests or additional information.
3. In case of media contact, notify the Battelle Project Manager immediately.
4. Your name will appear as one of the panel members in the peer review. Your comments will be included in the Final IEPR Report, but will remain anonymous.

Please submit your comments in electronic form to Richard Uhler, uhlerr@battelle.org, no later than January 31, 2011, 5 pm EST.

Independent External Peer Review
Columbia River at the Mouth, Oregon and Washington
Major Rehabilitation Evaluation Report

Final Charge Questions

GENERAL QUESTIONS

1. To what extent has it been shown that the project is technically sound, environmentally acceptable, and economically justified?

2. Are the assumptions that underlie the economic, engineering, and environmental analyses sound?

3. Are the economic, engineering, and environmental methods, models, and analyses used adequate and acceptable?

4. In general terms, are the planning methods sound?

5. Are the interpretations of analysis and conclusions based on the analysis reasonable?

MAIN REPORT

SECTION 1.0 -- INTRODUCTION

6. Is the project's purpose and scope complete and understandable?

7. What other information, if any, should be included in this section?

8. Has adequate public, stakeholder, and agency involvement occurred to determine all issues of interest and to ensure that the issues have been adequately addressed to the satisfaction of those interested parties?

9. Comment on the extent to which the existing conditions are clearly and adequately described.

10. Comment on whether the information presented supports the problem identified under the base condition.

SECTION 2.0 -- ECONOMIC CONSIDERATIONS

11. Has the base condition, without-project condition and summary of costs and benefits been adequately described, analyzed, and explained?

12. Does the National Economic Development (NED) Plan contrast to the base condition?

13. Is it clearly explained why navigation benefits were not analyzed?

SECTION 3.0 -- ENGINEERING CONSIDERATIONS

14. Is the description of functional and structural reliability clear and reasonable?

15. Was the Stochastic Risk-Based Life Cycle Simulation (SRB) model used in an appropriate manner? Is the description of how the model functions, the relative influence of model parameters and model calibration process clear and logical?

16. Comment on the repair and rehabilitation alternatives. Is the description of the different plans clear and distinct?

17. Comment on the engineering features for alternatives. Do the plan descriptions clearly indicate which features are incorporated into the various plans?

18. Comment on the evaluation of engineering features. Is the scope, function and analysis of the engineering features clearly described?

19. Comment on the general alternative development approach. Does the alternative evaluation presented follow USACE guidance?

20. Comment on the engineering evaluation of alternatives. Are the plans adequately evaluated based upon their engineering merit?

21. Has the sediment analysis been adequately performed and documented to support the movement of material that occurs during a breach event?

22. Has the analysis been adequately performed and documented to support reductions in channel maintenance dredging?

23. Does the analysis adopt adequate risk thresholds for different alternatives and are such thresholds uniformly consistent?

24. Are potential life safety issues accurately and adequately described under existing, future without project, and future with project conditions?

25. Has the rationale for head capping locations at each jetty been adequately explained?

26. Has the basis for the number and location of spur groins been adequately explained?

SECTION 4.0 -- ASSESSMENT OF ALTERNATIVES

27. Does plan selection reflect a full range of design alternatives?

28. Are the problems and opportunities appropriately defined and addressed in this study?

29. Are there any other constraints or objectives that should be considered as part of the project that would be important to reaching the projects final goals?

30. Do the alternatives adhere to the USACE Plan Formulation Criteria? Do they appropriately address the needs and objectives of the project? What additional information, if any, should be discussed?

31. Comment on the completeness of the project-specific criteria used in the comparison of alternatives.

32. Was the NED Plan appropriately identified and selected?

SECTION 5.0 -- ENVIRONMENTAL CONSIDERATIONS

33. Comment on the completeness of the environmental documentation. Have all National Environmental Policy Act (NEPA) requirements been satisfied?

34. Have the water resources in the project area been accurately described?

35. Comment on the thoroughness and accuracy of the marine and estuarine resource information presented.

36. Comment on the overall discussion of environmental effects due to the project.

37. Comment on the adequacy of available information used to characterize wetland resources within the study area.

38. Comment on whether the special status species and resource areas in the project area have been accurately described.

39. Comment on the adequacy of the environmental and without-project condition summaries in terms of data quality, timeliness of the data, and breadth of information covered.

SECTION 6.0 – CONSTRUCTION AND COST ESTIMATE

40. Comment on the overall adequacy and reasonableness of the detailed cost estimates.

41. Comment on the extent to which the cost summary is complete and consistent with the detailed analyses shown in this section.

42. Is the construction schedule adequate for completion of the recommended activities?

SECTION 7.0 – RECOMMENDATIONS

No questions.

SECTION 8.0 – REFERENCES

No questions.

APPENDICES

Appendix A1 – Coastal Engineering

43. Does Appendix A1 describe the coastal engineering history and challenges specific to the Mouth of the Columbia River?

44. Does Appendix A1 contain adequate information to assess coastal engineering at the Mouth of the Columbia River?

Appendix A2 – Reliability Analysis, Event Tree Formulation and Life-cycle Simulation

General Questions

45. Is the purpose of the model clearly defined?

46. Is the model diagram easily understood?

47. Does the model follow a logical programming path?

48. Does the model adequately capture and evaluate all of the relevant variables?

49. Can the model as described achieve the stated purpose?

50. Does the model accurately describe (model) repair activities and sequences? Is it modeling the repair activities similarly to how the repairs will be sequenced and performed?

Technical Quality

51. Comment on the overall technical quality of the model.

52. Is the model a realistic representation of the actual system?

53. Are the analytical requirements of the model properly identified?

54. Does the model address and properly incorporate the analytical requirements?

55. Are the assumptions clearly identified, valid, and do they support the analytical requirements?

56. Comment on the ability of the model to calculate benefits for total project life.

57. Has the design wave height of 55 feet been appropriately calculated and documented?

58. Have the waves generated by the model been validated against observed wave data?

Usability

59. Comment on the model's usability.

60. Are the model results easily understood?

61. Do the model results support the project objectives?

62. Is user documentation available and complete?

63. Is the model transparent and does it allow for easy verification of calculations and outputs?

Appendix B – Geotechnical Studies

64. Does the background information adequately describe the geologic history and conditions at the Mouth of the Columbia River and surrounding area?

65. Are all of the site specific and distinct geological features relevant to the project described and appropriately addressed in the engineering design?

66. Were risk and uncertainty sufficiently considered?

Appendix C – Economic Analysis

67. Comment on the assumptions and forecast methods used to calculate project benefits.

68. Comment on the reasonableness of the scenarios used to calculate benefits.

69. Comment on the method used to calculate the National Economic Development (NED) benefits.

70. Comment on the assumptions used in the calculation of present value of benefits.

71. Comment on the extent to which the NED benefits summary is consistent with and justified in the economic analysis.

Appendix D – Environmental Documentation

72. Comment on the ability of the proposed mitigation plans to address adverse impacts from the project.

73. Are the conclusions regarding the type and projected magnitude of adverse impacts to resources within the study area reasonable?

74. Comment on the appropriateness and comprehensiveness of the identified mitigation projects considered for addressing predicted impacts arising from the project.

Appendix E – M-CACES Cost Estimate for Recommended Plan

75. Comment on the overall adequacy and reasonableness of the detailed cost estimates.

76. Discuss the appropriateness of the explicit or implicit assumptions that are included in the cost estimates and whether assumptions are adequately addressed.

77. Comment on the extent to which the cost summary is complete and consistent with the detailed analyses provided in the study report.

Appendix F – Project Management Plan

No questions.

Appendix G – Schedule of Fully Funded Project Costs

No questions.

FINAL OVERVIEW QUESTION

78. What is the most important concern you have with the document or its appendices that was not covered in your answers to the questions above?

Subj: Review and Recommendations for Life-Cycle Simulation Model for the Jetties at the Mouth of the Columbia River, Oregon and Washington
Contract No. W912PL-08-D-0016; Task Order No. DT03

Dear Mr. Brodesser:

The purpose of this letter is to provide the results of an assessment of the Stochastic Reliability Based lifecycle simulation model (SRB) which evaluates maintenance strategies for the rubble mound jetties located at the Mouth of the Columbia River (MCR). Moffatt & Nichol (M&N) is under contract with the U.S. Army Corps of Engineers (USACE), Portland District, to prepare this review and provide recommendations for proceeding towards meeting the requirements of an approved planning model as defined by *EC 1105-2-412 - Assuring Quality of Planning Models*.

BACKGROUND

The SRB model is a computer simulation MATLAB® code that stochastically evaluates the environmental loading affecting each of the MCR jetties, and relates structural response (cross-section evolution) of each jetty to functional performance. The structure response is evaluated in terms of cross-section area change (loss) over time due to jetty degradation. Jetty repairs are activated within the SRB model after the jetty cross-section is reduced below a specified threshold value. Jetty repairs are calculated in terms of the tonnage of armor stone required to re-establish the jetty cross section to its standard dimensions. Life-cycle costs estimated by the SRB model include jetty repair and incremental dredging attributed to jetty degradation and loss of function. Because life-cycle costs are estimated using stochastic methods, their realization can be considered probabilistic. Although reliability is also calculated within the SRB model, reliability is not used to simulate structure response and related consequences (life-cycle cost). Reliability is modeled as a function of repair and maintenance, and is used as a supplemental metric to inform on overall jetty performance.

As part of the USACE review process, the model underwent an Independent External Peer Review (IEPR) and was subject to Headquarters (HQUSACE) review for approval of use. The IEPR panel had four highly critical comments regarding the SRB model; subsequently, the panel did not approve the model for one-time use.

The M&N approach towards assessing the model is based on a tiered approach as follows:

- Assessment of the critical IEPR comments for possible resolution;
- Review overall modeling approach to verify inclusion of all critical mechanisms;
- Review formulation of the critical mechanisms;
- Review model documentation for adequacy in describing mechanism formulations;
- Review implementation of the mechanism formulation in the MATLAB® code;
- Review calibration/validation of processes incorporated in the model; and
- Preliminary review of MATLAB® code for efficiency and transparency.

This evaluation focuses solely on the model approach for the North Jetty as it is assumed the overall approach will be similar for the South Jetty and Jetty A. Also, there has been some modification of the North Jetty model to address ATR Comments so it presumably represents the latest and best formulation.

The results of our assessment of the model and our conclusions and recommendations are described in the following sections of this letter. The evaluation of the IEPR comments is discussed first since appropriate resolution of these comments is critical for model approval. The remainder of the report deals with the assessments of the overall approach, the MATLAB® code, and the model documentation. The conclusions and recommendations are in the last section.

EVALUATION OF IEPR COMMENTS

There are four significant comments from the IEPR that require resolution if the model is to be accepted as an authorized planning model. Each of these comments is addressed in this section.

Comment # 2: The analysis of the sediment transport process is not comprehensive, and the data and analysis do not support the conclusions concerning large movement of sediment during a breach event.

This comment addresses the sediment transport into the navigation channel as a result of a breach in the Jetties. The breakwater has breached in the past which has allowed sediment transport into the navigation channels, but the quantities and mechanisms have not been well documented. The disagreement between the Coastal Modeling System (CMS) Model Study is also of concern, although clearly the CMS model evaluation utilized a time scale inconsistent with the actual processes. The CMS model simulated the breach over a period of 6.5 days whereas the time frame for the observed shoaling related to the breach occurrence was on the order of months. This time frame difference would explain the difference in shoaling magnitude.

The recommendation from the IEPR that a more thorough investigation of the shoaling processes be incorporated is likely inconsistent with the time frame for the model implementation. After evaluation of the costs associated with the breach occurrences, a more appropriate approach may be to incorporate the emergency repair to the Jetty and disregard the dredging costs associated with the breach. This approach would satisfy the bulk of the IEPR comment. If the breach is considered in a planning scenario, some reasonable cost could be incorporated in the planning outside of the model framework.

Comment # 4: The SRB model by itself has very limited value for analyzing alternatives and is not a substitute for conventional economic and engineering analysis.

This IEPR comment is a blanket statement which leaves very little room for a response. However, it appears that there is a clear misunderstanding about what the model does and how it performs. The primary response to this comment would be to provide more transparency in the model formulations and how these formulations are appropriate for the MCR jetties. The formulations need to be validated to illustrate confidence in the predictive capability of the model based on historical jetty maintenance experiences.

It should also be emphasized that the model should be considered as a comparison tool and that it does not make the final decision. The IEPR review seemed to believe the model concluded with a decision which is incorrect. Engineering and economic judgment is still required once the model evaluation of alternatives is completed.

The portion of the comment related to armor rock breakage and slip circle failure is beyond the scope of the model and the comment should be considered invalid. The model is based on the assumption that the bulk of the damage is related to coastal processes and that these processes are included in the model with additional damage sources accounted for in the selection of the damage function calibration factor. This comment can also be addressed similar to the response to Comment #8 below.

Comment # 7: The basis of design and design environmental criteria are vague, not consistent within the report, and not consistent with conventional coastal engineering design practice.

The resolution to this comment is to clarify that the model is for a 50-year planning horizon and that all design criteria should be based on 100-year return interval. All other references to various 50-year periods should be clarified within the documentation.

Comment # 8: The models and analyses of jetty failure do not include all significant processes.

This comment suggests that additional geotechnical data should be gathered in the vicinity of the jetties, specifically boring data. Based on discussions with the Portland District personnel, we understand the generally feeling that there is adequate geotechnical data for the design of the jetties. This comment is best addressed by documenting and explaining the extent of the geotechnical data that has been assembled for past maintenance efforts. It can also be pointed out that the predominant processes impacting the stability of the jetties is related to the coastal processes more than geotechnical issues based on historical experience with the jetties.

To a great extent, the soil properties related to scour are addressed in the model based on calibration against historical observations and this implicitly considers this facet of the geotechnical factors.

ASSESSMENT OF MODEL APPROACH

Model approach was reviewed with a general purpose to identify fundamental issues and discrepancies in the model. The main comments are provided below.

1. The model calculations and most of governing input parameters were defined with a hard coded jetty segment size of 100 ft. It is understood, that the segment length was selected as a typical length of repairs and damage. Greater flexibility in the model application and calibration could be achieved if the internal segment size for calculations is made adjustable.

2. The present approach defines one year as overall time step in the model and calculates damage to each segment cumulatively based on the number of storms in each year. It would be more logically correct to iterate over a sequence of storms in each year and then calculate damage to the jetty segments in each storm. That would allow more flexibility to evaluate damage on any different time step and, if needed, on a storm-by-storm basis.

3. The number of storms is limited to 52 historically observed storms, for which measured storm parameters are applied. The selected set of storms represents the general population of storms in the area sufficiently well. However, use of preselected storms and water levels in Monte Carlo simulations may impose some limitation in the analysis. During the storms which have a potential to damage the jetties wave heights at the structures are limited by depth. Therefore, wave direction (which governs distribution of wave heights along the jetties) and more importantly water level are the main parameters which control the level of damage and distribution of damage along the structure. The model presently utilizes only three water levels for each storm, while more variability could be added to water levels in the MC simulations. Additionally, it would be advantageous to provide a guidance on how to define a set of synthetic storm conditions which represent the population of storms in the area where detailed observations of the storms is not available.

4. The wave parameters for segment damage function were extracted from STWAVE model output. It is expected that the wave parameters vary along each segment of the jetty and for every segment a single set of parameters (wave height, period, etc) was identified. A description of how to select these values from the STWAVE results would be beneficial.

5. Tidal currents, river floods and storms cause significant morphological changes around the jetties such as scour, channel migration, and shoal evolution. These changes were approximated in the model by historic trends. It would be advantageous to include the possibility to modify these trends as a part of “what if” alternative simulations. For example, what if scour at the toe of the North jetty expanded and resulted in additional damages.

6. The deterministic and random variables should be clearly defined in the model. The random variables are defined in the beginning of each MC simulation. The deterministic are either preset or calculated using formulas based on other variables.

7. Formulas for static (toe scour and slope failure) and dynamic (wave breaking and overtopping) effects on jetty damage needs to be verified. These formulas define the governing procedure of each jetty's response to a storm. Accuracy of these formulations is crucial. Most formulas from accepted procedures deal with prediction of damage to a breakwater from a single storm under the assumption that the breakwater keeps the initial profile shape. If the jetty sustains damage from one storm to another, the profile will adjust by stone displacements. Currently, the model accumulates damage from multiple storms in one year without considering adjustment of the structure between the storms. It is assumed that the second storm will have the same damage as the first one, which may lead to overestimation of the total damage.

8. The model utilizes a simplified parameterization of the cross-section profile of the jetty. The cross-section is divided at −5 ft MLLW into top and bottom layers. The top layer is affected by dynamic damage, and the bottom layer is affected by static damage. Since damage is calculated as loss of area, additional assumptions were applied to the slopes, top width and jetty height to match the remaining area. It is clear that the resulting profile is only an approximation of the actual damaged profile. A clear explanation of the process of profile adjustment would help in understanding how stone volumes in the top and bottom layers are calculated, as well as reused and lost stone.

9. Approximation of jetty damage from a storm is the key element of the entire model. The damage functions were defined from lab tests for selected conditions, such as normal profile, damaged profile, etc. They represent relationships between wave heights and lost cross-section areas as A = f(H). The damage functions were calibrated in the model by using shift in wave height as $A = f(H - H_{shift})$, which essentially moves the threshold when damage begins. It was identified that each damage function could have its own shift parameter, but only if that function was utilized in the calculations. It is possible that damage functions for a new configuration of the jetty may be slightly different, which make it difficult to select the appropriate shifts for forecast conditions under new alternatives.

10. Shoreline erosion/accretion is approximated in the model from the historic trend which is a reasonable approximation. Additional flexibility in the model could be achieved by allowing easy modifications to these trends or specifications of new ones based on the jetty repair alternatives. For example, if an alternative can cause acceleration in shoreline erosion/accretion. It is also very conservative to assume that <u>all</u> eroded sediments are transported into the navigation channel.

11. Two independent components, financial and structural, should not be combined into one MC simulation. It would be better to separate them into two MC analyses by making

structural components (storms, damages, and repairs) completely independent of financial components (price for repairs and dredging). This should answer the question—what if the storm sequence is the same, but the strategy on the repairs changes, would the jetty reliability be the same? Then results of these MC simulations can be recalculated with variable prices. This second simulation would tell if the prices change, will this affect an earlier decision about the repair strategy?

COMMENTS ABOUT MATLAB® CODE

The comments about the model code are given below.

1. The simulation folder contains many files of different types, including Excel spreadsheets, text files, and MATLAB® binary files. There is no distinct difference between the names of input and output files or perhaps folders to isolate input and output files in different locations.

2. The main input file is called *AA_XLS_new.mat*, where AA is the jetty name. The variables in this file were derived by a preprocessing script from Excel files. There are many variables in the file but no descriptions. Some references can be found by referencing the preprocessing script, but without MATLAB®, there is no easy way to modify the file or check the content.

3. The main model script is called *event_tree_NNN.m*, where NNN is name of the jetty and alternative. The file consists of more than 7300 lines. About 2000 lines are dedicated to plotting and output. This is a very large file to edit and navigate, considering the fact that most modifications to model control variables should be done in that file. Additionally, there are four subroutines which are stored in separate files. None of the scripts include online help or detailed description of the input/output parameters. Some subroutines have more than 20 input variables. The input/output and variable handling is not done in a structured manner.

4. Many variable names reflect the name of the jetty that the routine was developed for. This practice creates unnecessary difficulties for comparing between different versions of the code. For example, it would be difficult to compare codes between NJ and SJ to verify if the two routines work similar.

5. The routines create too many variables which are stored in the same workspace. Some structuring of the variables could potentially help in review of model results.

6. There are too many hard-coded coefficients in the scripts. Many of them are not placed in the same part of the code and are spread throughout the code. The hard-coded coefficients are mixed with process control parameters. This creates difficulties in identification of parameters which can be changed to modify the way MC simulations are performed.

7. There are many parameters which define particular events, for example, *Repair_Crest_el_1939* or *Crest_El_2006*. These variables probably have very little information for forecast mode. Therefore, it is clearly a question if hindcast and forecast modes can be separated into different subroutines, while forcing functions remain the same.

8. The alternatives are implemented within the same main code. The selection is done by setting a single variable *fut* in the beginning of the code. It is not transparent how additional alternatives can be added or existing ones modified. There are numerous IF statements, which seem to depend on the value of *fut*.

9. Some graphical output is created for a jetty segment selected before the MC simulation. There is probably a way to create plots for another segment without the need to rerun simulations, however it is not obvious. Graphical output could be completely separated from the main routine to allow more flexibility in creation of figures without the need to rerun a simulation. This is especially important, since MC simulations give stochastic (variable) results.

COMMENTS ABOUT DOCUMENTATION AND USER'S MANUAL

The *Model Documentation Report* provided a general description of the model background and principal algorithms. Sufficient details were given on the basic model organization, principles of operation, and main input and output. A part of the report named *Model Operation Guide* included some information on the calibration process, model setup, selection of alternatives (repair strategies), and model inputs and outputs. This part was found to be rather brief and in most cases only indicated general locations (a script name or data file) where modifications can be done to allow the user to change inputs into the model. Explanation of the model calibration was not complete. In particular, specific details about how the values of calibration parameters were used in the forecast mode were not included.

Most of input parameters (damage function, STWAVE model output, jetty configurations) were defined in a series of Excel files. However, most of the parameters in these files were self explanatory, and it would be difficult to make significant changes to the model inputs without modifications to the main code of the model. For example, the damage functions were defined by hard-coded variables with fixed sizes. Any changes to the damage function array size would require modification in the corresponding Excel file, preparation script, and the main code. A detailed description of how would be accomplished is not provided.

CONCLUSIONS AND RECOMMENDATIONS

Our overall recommendation is to retain the existing model and make improvements to satisfy planning model approval requirements. The basic premise of the model is sound and a great deal of effort has gone into formulating the important processes impacting the jetties and the maintenance procedures available for jetty repair.

The recommendation to retain the existing model is based on several considerations. The first consideration is the requirement to complete the evaluation of maintenance plan alternatives and recommend the most appropriate plan within the next few months. Several years have gone into the development of this model. Knowing that objectives for the model evolved over this time period, it should not take as long to develop a model from scratch. However, we do estimate that model development from scratch would require at least a year or two including model approval for use in the evaluation of planning alternatives. This time frame does not meet the requirements of the Portland District schedule.

The second consideration for retaining the existing model with improvements is the engineering cost associated with development from scratch. While we have not worked up a detailed cost estimate for a scope of this magnitude, the fee for M&N to do this work would likely be approximately $400,000. Portland District personnel as well as review personnel would also be participating in this project requiring additional engineering costs. Working with the existing model and making the recommended modifications will be significantly less, likely less than half of this budget.

Improvements are required to meet the requirements for an authorized planning model. Specifically, the following improvements should be implemented:

1. Modularize the model code using the existing approaches where they are appropriate. Specifically, separate parts of the code related to the following:
    - Setup of global variables
    - Setup of MC simulation
    - Specification of alternatives
    - Calculation of damage functions
    - Geometry adjustment after damage
    - Creation of output and plotting
2. Validate independent modules based on available literature and previous experience with the MCR jetties. Alternative formulations of the damage functions used in the model should be provided for comparison of model results with alternative published analytical formulations.
3. Calibration results for the model need to be clearly documented. To accomplish this, the calibration process and parameters must be clearly documented within the model and in the model output and reporting. Additional performance metrics can also be extracted from the model results and clearly presented. This will help improve the transparency of the model for those not directly involved with setting up and running the model.
4. During the process of modularizing the existing model, the structure should be changed to allow a single model code capable of evaluating alternatives for all three jetties.

5. Improvements are required in the user interface to allow the user to easily review all input and output parameters. Existing hard-coded parameters should be removed from the model code to provide greater transparency.

6. A well-documented user's manual needs to be prepared to allow qualified modelers to apply the model to evaluate alternatives. The majority of this effort would be improvements to the *Model Operation Guide*.

7. The economic and structural analyses should be separated into independent routines. The economic analysis calculations would be based on the output from structural simulations with an interface between the two models. This approach also permits the use of different economic analysis approaches for a single structural simulation.

8. Additional metrics for evaluating alternatives can be output from the model to assist in the economic evaluation of the alternatives. These include structural and functional reliabilities, stone volumes which were lost, placed, or moved, and others. A facility can be created to easily calculate and output new metrics as needed. These additional metrics will add to the transparency of the model results and go a long way towards gaining approval for the model as an authorized planning model.

9. The shoaling related to jetty breaching should be eliminated while the repair requirements to the jetty section should be retained for the breaching. This recommendation is based on IEPR comments suggesting that it will be difficult to get a professional consensus regarding the appropriate shoaling volume and distribution. As this shoaling volume is relatively small compared to the morphological changes related to jetty tip retreat, the impact to costs in the alternative analysis is relatively minor.

There are two additional issues which are fundamental to an appropriate modeling approach. The first issue is the morphological assessment within the model related to recession of the jetty tips. Decisions regarding future maintenance of the jetties needs to address whether the current location should be retained as the optimal location or whether the tips should be allowed to recede further. The current approach for morphological impacts as implemented within the model does not address this decision. A much more sophisticated morphological modeling approach is required to address this issue. However, given the available time to evaluate the jetty maintenance alternatives and the high likelihood that whatever approach is used will extend controversy of the model applicability, we do not recommend development of a more detailed morphological model at this point. However, this component could be included at a later date when scheduling or application requirements permit.

The second fundamental issue that should be addressed further is the damage functions currently used in the model. The damage functions are fundamental to the model results and therefore their application in the model should be accurate and transparent. An analysis should be performed in order to define the possibility of a clearer approximation for the damage functions derived from physical model results. The calibration process for the shift parameter in the damage functions will also be reviewed with an attempt to improve the calibration process. This task may or may not result in a better damage function specification or calibration parameter selection; however, it will become a part of code modulation and restructuring task and would permit comparison of alternative damage function approaches.

Given the recommended tasks above for model improvements and realizing that time is of the essence in getting the model approved for this application, we estimate that the work to accomplish these tasks would require approximately 3.5 months. If work begins immediately, the project would be completed by approximately mid-January 2012. This work would include getting approval for model use, simulating the currently identified maintenance alternatives, and assistance in preparing the alternatives assessment report.

It has been a pleasure to be involved with this challenging project. We hope to continue to be of assistance with moving this model forward and making it a useful tool for evaluating maintenance strategy alternatives. Please do not hesitate to contact me if you have any questions or concerns regarding our assessment of the model and the potential for application to the MCR jetty maintenance planning.

Sincerely,

MOFFATT & NICHOL

STATEMENT OF WORK FOR
MODIFICATION No. 2

CONTRACT NO. W912PL-08-D-0016, MOFFATT & NICHOL
TASK ORDER NO. DT03, LIFE-CYCLE SIMULATION MODEL SUPPORT FOR THE JETTIES AT THE MOUTH OF THE COLUMBIA RIVER, OREGON AND WASHINGTON

1. BACKGROUND. During Phase 1 of the task order, the AE team assessed the current SRB model architecture, code, and documentation; the three outstanding IEPR comments and Assuring Quality of Planning Models (EC 1105-2-412), and made a recommendation on the most efficient approach to obtain model approval. The AE team was asked to provide details on how to achieve model approval and respond to open IEPR comments by either:

(1) Improve and revise existing model architecture and code;
or
(2) Start over with entirely new planning model

The AE team's recommendation is to improve and revise the existing model code. The team identified nine specific recommendations to improve the model. Those recommendations will be used as the first nine tasks for this modification. Additional tasks will be identified for technical writing, plan formulation and Report Editing.

2. OBJECTIVES. This modification of the task order is for phase II.

During Phase 2 the CENWP's product delivery team will work collaboratively with the AE team to develop the following:

- A fully documented model which has been validated and verified, with input and output files, and a user's manual – meeting the requirement of EC 1105-2-412.
- Clearly defined design criteria and basis for design.
- A range of alternatives leading to a least-cost plan.

The AE Team members under this task order shall possess the following skill sets:

- MATLAB programmer with 5 years experience.
- Senior coastal engineer with 20 years experience in the design of coastal structures.
- Economist with 10 years USACE plan formulation experience (Phase 2).

3. MANDATORY SERVICES TO BE PROVIDED.

a. <u>Task 1: Modularize the model code</u> The model code architecture will be modified utilizing the existing modeling approaches where they are appropriate, and separating the parts of the code related to the following:

- Setup of global variables

- Setup of Monte Carlo simulation
- Specification of alternatives
- Calculation of damage functions
- Geometry adjustment after damage
- Creation of output and plotting

b. Task 2: Validate Independent modules The independent modules that are established in Task 1 will be validated for functionality and accuracy utilizing available literature and previous experience with the MCR jetties. Alternative formulations of the damage function used in the model will be developed by the AE team for comparison of model results with alternative published analytical formulations.

c. Task 3: Document Calibration Results The AE team will calibrate the revised model clearly documenting the calibration process and the parameters used in the model and in the model output and reporting. Additional performance metrics will also be extracted from the model results and clearly presented when feasible. The goal of documenting the calibration process and parameters used is to provide transparency of the model functions for reviewers not directly involved with setting up and running the model.

d. Task 4: Develop Single Model Code for all Three Jetties During the process of modularizing the existing model code, the structure will be changed to allow a single model code capable of evaluating all three jetties.

e. Task 5: Improve User Interface. Develop a user interface that will permit the user to easily review all input and output parameters. Existing hard-coded parameters will be removed from within the model code to provide greater transparency of how individual parameters affect model output.

f. Task 6: Prepare Users Manual. A well documented user's manual will be prepared in order to allow qualified modelers to apply the model to evaluate alternatives. The majority of this effort will be improvements to the existing Model Operation Guide.

g. Task 7: Separate the Economic and Structural Analysis. The economic and structural analysis will be separated into two independent routines. The economic analysis calculations will be based on the output from the structural simulations with an interface between the two models. This approach will permit the use of different economic analysis approaches for a single structural simulation.

h. Task 8: Provide the Capacity to Output Additional Metrics from Model. Create a facility to calculate and output additional metrics as needed. New metrics may include structural and functional reliability, stone volumes which were lost, placed or moved and others not yet identified. Additional metrics will be used to enhance the transparency of the model results with the intent of facilitating model approval.

i. Task 9: Remove Breach Shoaling. The in-channel shoaling volumes and required additional dredging will be removed from within the model. Retain the damage repair requirements to the jetty section and track as a breach in order to distinguish from a repair volume related to general damage. Tracking the damage as a breach will enable the model to indicate at what point a breach is probable and it will help inform maintenance strategy and repair cost.

j. Task 10: Utilize Improved Model. Assist USACE Product Development Team with the evaluation of alternatives utilizing the improved SRB model. The alternatives should remain the same or similar to the previously used alternatives, however, the base condition will require to be altered to represent the changed site conditions that will occur as a result of the North Jetty Major Maintenance Report (NJ MMR) that was written after the MCR Major Rehabilitation Report and has been submitted for the FY 2012 budget. Provide an economist that will assist the USACE PDT with plan formulation, evaluation of the alternatives and performing the economic analysis.

k. Task 11: Incorporate New Data and Streamline Report. Assist USACE Project Development team with the incorporation of results from the new model runs into the existing Major Rehabilitation Report. During and prior to the process of incorporating the new model data the AE team will review the report and with PDT concurrence make modifications that increase the readability of the report. The goal of the modifications shall be to retain the existing information while shaping the report into a more concise document.

4. MANDATORY SUBMITTALS TO BE PROVIDED. Under this modification, the Contractor shall provide the following:

> **a. Submittal 1 Model code and Documentation** user's manual, revised A1 and A2 appendices reflecting model code changes and validation and verification files.
>
> **b. Submittal 2 Revised Major Rehab Report.** Provide the text and technical writing services to revise the existing Major Rehabilitation report as follows; describe the basis of design and engineering criteria used for plan formulation incorporating modifications to the alternatives, justification for head-capping and spur groin locations and selection of alternative.

5. SCHEDULE. All services required under this task order modification shall be completed no later than 20 January 2012. It is anticipated that the Notice to Proceed (NTP) for this modification will be issued by Oct 14, 2011.

6. ONLY WHEN AUTHORIZED (OWA) SERVICES. The following OWA tasks will be negotiated and funded at time of award. The Contractor shall not perform any OWA services without specific written direction from the Contracting Officer's Representative.

a. <u>Additional Meetings</u>. Establish two (2) units of additional OWA meetings. Each unit shall be for three (3) people for two (2) days. Costs shall include travel and per-diem to Portland, Oregon.

Bernard Moseby
National Deep Draft Navigation Planning Center of Expertise
Mobile District, USACE
PO Box 2288
Mobile, AL 36628-0001

Dear Mr. Moseby:

The purpose of this letter is to inform you that Portland District is submitting to the National Deep Draft Navigation Planning Center of Expertise (DDNPCX) a reliability model of the jetty system at the Mouth of the Columbia River (MCR). Portland District requests that the Center conduct the approval process of this model per EC1105-2-407.

This computer model is to be used in the Major Rehabilitation Study of the jetties at the Mouth of the Columbia River (MCR). The model is written in Matlab and is actually three separate models, one for each of the jetties there; North Jetty, South Jetty, and Jetty "A". The model and supporting files have been placed on the USACE public FTP location: ftp://ftp.usace.army.mil/pub/nwp/MCR_SRB_review/

These files will be available for ten days on the FTP site. The files will need to be re-posted if you do not download them within this timeframe.

NWP Points of Contact are as follows:

Rod Moritz 503-808-4864, Technical expert;
Jason Magalen, 503-808-4832, Technical assistant;
Tom Hackett, 503-808-4769, Planning POC;
Brian Shenk, 503-808-4221, Economics POC.

Because of the size and complexity of the model, we are recommending that the model reviewer or reviewers communicate periodically with key NWP personnel during the review process. We would like to work with you once the review team is developed to establish an appropriate way to check in on comments, and maintain the review schedule. If you would like, we are available to conduct a kick off meeting with the review team to introduce and explain the model.

Please provide the reviewers names, and the review and approval schedule. Tom Hackett of my staff is managing the review process for the District and he will be in contact with you during the review period. You may contact him at (503) 808-4769 or email at thomas.w.hackett@usace.army.mil.

Sincerely,

for Christine McBurdan

CENAE-EP-HG 24 August 2010

MEMORANDUM FOR: Mr. Bernard E. Moseby, CESAM-PD-FE, Chief, Economic Analysis and Deputy Director, Deep Draft Navigation Planning Center of Expertise

SUBJECT: Review and Certification Letter for the Mouth of the Columbia River (MCR) Stochastic Reliability Based (SRB) Lifecycle Model for the MCR Major Rehabilitation Report

The following is the background information on the review process for the certification of the MCR SRB Lifecycle Model:

1. In October 2009, a request was made by the NWP PM to the ATR team leader to assist in obtaining model certification of the Mouth of the Columbia (MCR) Stochastic Reliability Based (SRB) model. This process was conducted using current USACE planning guidance and coordinated through the Deep Draft Navigation PCX to request from USACE Headquarters an "approved for use" status of the MCR SRB model.

2. A technical review of the MCR SRB model was initiated in November 2009 and has continued to date utilizing both part of the ATR team (Mr. Robert C. Patev, Team Leader and Mr. Wally Brassfield, ATR cost team member) and Mr. John Winkelman, a Coastal Regional Technical Specialist (RTS), from North Atlantic Division (NAD). Since the MCR SRB model was developed using the MATLAB language/software, Mr. Winkelman was an important part of this team due to his knowledge of the software, his technical position as a coastal engineer/planner Regional Technical Specialist with the HSDR PCX, and his past work experience in SPD on West Coast coastal navigation projects.

3. The review was begun in November 2009 by Mr. Patev and Mr. Winkelman and included a visit to CENAE by Mr. Hans Moritz, who is the developer of the MCR SRB model. The meeting lasted approximately two days and included a detailed presentation of the model code, model development assumptions, variable and model input descriptions, a discussion of the model output, and a lengthy discussion of model philosophy. Questions or comments generated prior to and during the meeting were documented and addressed as part of the Dr. Checks review process. Twenty three comments were generated and submitted into Dr. Checks in January 2010. Questions and comments were related to model coding, model variables and model constant value selection, model assumptions, and limited coastal engineering issues. Each issue and question was answered and/or addressed satisfactorily.

4. Following this meeting and installation of the MCR SRB MATLAB code at NAE, a number of variables and their ranges were defined to investigate model performance, sensitivity, and stability of the code. This was performed in terms of engineering reliability aspects of the program only. During this phase of the review, Mr. Moritz provided the review team with a list of key variables and constants within the code for validation. Many of these variables were discussed further during a number of

email/phone exchanges during this phase. After these communications and detailed examination of the code, the values selected in the model for engineering parameters were determined to be reasonable and based upon a sound engineering decision process. When these values were changed in the model, noticeable changes to the model output were recognized, but the model did not produce any unreasonable results in terms of engineering reliability.

5. The values for costs included in the MCR SRB model were reviewed and modified by Mr. Brassfield in July 2010. However, the validation of the methods and mathematical calculation for the estimation of the economic consequences produced by the model has not been reviewed by any team member since this was outside of their areas of expertise.

The following limitations, review assumptions and technical recommendations were drawn by the review team during their review:

1. With a model of this size and complexity it is difficult to determine if all of the code is error proof or if the model is providing the exact correct answer. However, based on the review, as described, the model, from a coastal analysis/performance stand point does appear to be reasonable and is a reasonable tool for determining the future, relative performance of various maintenance schemes for the MCR jetties discussed in the MRR. As with any model of this complexity, and for a system of this complexity, the precise numbers and resulting values are likely not absolutely correct but instead are reasonable and relatively correct between alternatives.

2. This model and code has only been reviewed as to what was included in the code installed at NAE in 2009. This review was limited only to the aspects of the engineering reliability and not the actual consequence determination in the program. The cost inputs have been reviewed by the ATR cost team member but the application of the economics to the outputs has not been validated as part of this review. In addition, any additional changes or modifications of the code should be reviewed by the ATR team to determine the validation of those modifications to the code and the replication of the results with previous versions of the code.

3. The MCR SRB model was developed to perform an integrated analysis of both engineering reliability and consequence assessment. Typically, major rehabilitation models are developed separately into stand alone models for engineering reliability and economic consequences. If the schedule permits, I would strongly recommend that the SRB process and results be validated with a simpler model using hazard functions from the SRB reliability curves and the development of consequences using a traditional economic simulation model.

4. During the Independent External Peer Review (IEPR), it is important to provide the additional documentation and explanations discussed in my previous comments. Also, the face to face meeting for explaining the model is essential due to the complexity of the model. This is a model that is trying to meet a difficult USACE planning objective that covers an immensely complicated coastal engineering project and forecasts an uncertain

future. It should also be made clear what the purpose of the model is, and that this is a project specific model that has been developed, honed, and calibrated for this specific project area. The numerous factors and variables, etc. within this model, to a great extent, are project specific and are not to be used in a generalized model for other USACE projects.

5. Based on the information presented above, I recommend that the MCR SRB lifecycle model be certified as is and a request be sent to USACE Headquarters as “approved for use” for the MCR Major Rehabilitation Report only.

If there are any questions regarding this memorandum, please do not hesitate to contact me at your earliest convenience.

Robert C. Patev
ATR Team Leader

18 January 2011

MEMORANDUM FOR COMMANDER, South Atlantic Division, ATTN: WILBERT V. PAYNES, (CESAD-PDS-P)

SUBJECT: Model Certification – Approval for Use, Columbia River at the Mouth, Oregon and Washington, Major Rehabilitation of the Jetty System at the Mouth of the Columbia River, Stochastic Reliability-Based (SRB) Model

1. References:

   a. EC 1165-2-209, Civil Works Review Policy, 31 January 2010

   b. EC 1105-2-412, "Assuring Quality of Planning Models" dated 20 July 2009,

   c. EC 1105-2-407, "Planning Models Improvement Program: Model Certification" dated 31 May 2005.

   d. Memorandum, CECW-CP, 30 March 2007, Subject: Peer Review Process

   e. Supplemental information for the "Peer Review Process" Memo, dated March 2007

2. In accordance with EC 1165-2-209, "Civil Works Review Policy" Model Certification – Approval for Use, the Major rehabilitation of the Jetty System at the Mouth of the Columbia River, Stochastic Reliability-Based (SRB) Model, has been coordinated with and executed through the Deep Draft Navigation Planning Center of Expertise (DDN-PCX).

3. The review was a Level I review - for highly complex models used in decision-making where there could be a high risk of making an incorrect investment decision.

4. The review was performed by Robert C. Patev, CENAE-EP-WG, Team Leader and John Winkelman, CENAE-EP-WM, New England District, Corps of Engineers. The Model Assessment Criteria documentation that supports a recommendation of 'Approval for Use' for the SRB Model is enclosed. The Deep Draft Center is requesting coordination of the enclosed certification package through the Planning CoP Leader for processing, review and recommendation.

4. The Deep Draft Navigation Planning Center of Expertise (DDN-PCX) point of contact is Bernard Moseby, CESAM-PD-FE, (251)-694-3884.

MEMORANDUM FOR MR. ERIC V. BLUHM (CENWP-PM-F), PROJECT MANAGER, PORTLAND DISTRICT, U.S. ARMY CORPS OF ENGINEERS, POST OFIICE BOX 2946, PORTLAND, OREGON 97208-2946

SUBJECT: Review Plan Approval, Mouth of the Columbia River Jetties Major Rehabilitation O&M, Portland District, Portland, Oregon

1. The Deep Draft Navigation Planning Center of Expertise (DDNPCX) has reviewed the Review Plan (RP) for the subject study and concurs that the RP satisfies peer review policy requirements outlined in Engineering Circular (EC) 1165-2-209 Civil Works Review Policy, dated 31 January 2010.

2. The review was performed by Mr. Bernard E. Moseby, Technical Director, DDNPCX. The RP checklist that documents the review is enclosed.

3. The DDNPCX recommends the RP for approval by the MSC Commander. Upon approval of the RP, please provide a copy of the approved RP, a copy of the MSC Commander Approval memorandum, and the link to where the RP is posted on the District website.

4. Thank you for the opportunity to assist in the preparation of the RP. Please coordinate any Agency Technical Review (ATR), Independent External Peer Review (IEPR), and Model Certification efforts outlined in the RP with the Deputy Director, DDNPCX at (251) 694-3884.

Review Plan Checklist
For Decision Documents

Date: 5/30/2012
Originating District: Portland District
Project/Study Title: Mouth of the Columbia River Jetties Major Rehabilitation O&M
District POC: Eric V. Bluhm Project Manager
PCX Reviewer: Bernard Moseby

Please fill out this checklist and submit with the draft Review Plan when coordinating with the appropriate PCX. Any evaluation boxes checked 'No' indicate the RP may not comply with EC 1165-2-209 (31 Jan 2010) and should be explained. Additional coordination and issue resolution may be required prior to MSC approval of the Review Plan.

REQUIREMENT	REFERENCE	EVALUATION
1. Is the Review Plan (RP) a stand alone document?	EC 1165-2-209 Para 7a	Yes ☒ No ☐
a. Does it include a cover page identifying it as a RP and listing the project/study title, originating district or office, and date of the plan?		a. Yes ☒ No ☐
b. Does it include a table of contents?		b. Yes ☒ No ☐
c. Is the purpose of the RP clearly stated and EC 1165-2-209 referenced?		c. Yes ☒ No ☐
d. Does it reference the Project Management Plan (PMP) of which the RP is a component?		d. Yes ☒ No ☐
e. Does it succinctly describe the three levels of peer review: District Quality Control (DQC), Agency Technical Review (ATR), and Independent Technical Peer Review (IEPR)?		e. Yes ☒ No ☐
f. Does it include a paragraph stating the title, subject, and purpose of the decision document to be reviewed?		f. Yes ☒ No ☐
g. Does it list the names and disciplines of the Project Delivery Team (PDT)?* **Note: It is highly recommended to put all team member names and contact information in an appendix for easy updating as team members change or the RP is updated.*	EC 1165-2-209 Appendix B Para 4a	g. Yes ☒ No ☐ **Comments:**

2. Is the RP detailed enough to assess the necessary level and focus of peer review?	EC 1165-2-209 Appendix B Para 3a	Yes ☒ No ☐
a. Does it indicate which parts of the study will likely be challenging? b. Does it provide a preliminary assessment of where the project risks are likely to occur and what the magnitude of those risks might be? c. Does it indicate if the project/study will include an environmental impact statement (EIS)? *Is an EIS included? Yes ☐ No ☒* *If yes, IEPR is required.* d. Does it address if the project report is likely to contain influential scientific information or be a highly influential scientific assessment? *Is it likely? Yes ☒ No ☐* *If yes, IEPR is required.* e. Does it address if the project is likely to have significant economic, environmental, and social affects to the nation, such as (but not limited to): • more than negligible adverse impacts on scarce or unique cultural, historic, or tribal resources? • substantial adverse impacts on fish and wildlife species or their habitat, prior to implementation of mitigation? • more than negligible adverse impact on species listed as endangered or threatened, or to the designated critical habitat of such species, under the Endangered Species Act, prior to implementation of mitigation? *Is it likely? Yes ☐ No ☒* *If yes, IEPR is required.*	EC 1165-2-209 Appendix B Para 3a EC 1165-2-209 Appendix B Para 3a EC 1165-2-209 Appendix B Para 1 EC 1165-2-209 Para 15d EC 1165-2-209 Appendix B Para 7a EC 1165-2-209 Para 11d(3)(a) EC 1165-2-209 Para 11d(3)(a) EC 1165-2-209 Para 11d(3)(a)	a. Yes ☒ No ☐ b. Yes ☒ No ☐ c. Yes ☒ No ☐ d. Yes ☒ No ☐ e. Yes ☒ No ☐ **Comments:** An EA will be included

f. Does it address if the project/study is likely to have significant interagency interest? *Is it likely? Yes ☒ No ☐* *If yes, IEPR is required.* g. Does it address if the project/study likely involves significant threat to human life (safety assurance)? *Is it likely? Yes ☒ No ☐* *If yes, IEPR is required.* h. Does it provide an estimated total project cost? *What is the estimated cost: >$45.0 million* *Is it > $45 million? Yes ☒ No ☐* *If yes, IEPR is required.* i. Does it address if the project/study will likely be highly controversial, such as if there will be a significant public dispute as to the size, nature, or effects of the project or to the economic or environmental costs or benefits of the project? *Is it likely? Yes ☒ No ☐* *If yes, IEPR is required.* j. Does it address if the information in the decision document will likely be based on novel methods, present complex challenges for interpretation, contain precedent-setting methods or models, or present conclusions that are likely to change prevailing practices? *Is it likely? Yes ☒ No ☐* *If yes, IEPR is required.*	EC 1165-2-209 Appendix B Para 7a EC 1165-2-209 Appendix E Para 1a EC 1165-2-209 Para 11d(1)(b) EC 1165-2-209 Para 11d(1)(d) EC 1165-2-209 Para 16c(2) ,	f. Yes ☒ No ☐ g. Yes ☒ No ☐ h. Yes ☒ No ☐ Comment: Estimated costs are Greater than $45 million. i. Yes ☒ No ☐ j. Yes ☒ No ☐ **Comments:**
3. Does the RP define the appropriate level of peer review for the project/study?	EC 1165-2-209 Para 7a	Yes ☒ No ☐
a. Does it state that DQC will be managed by the home district in accordance with the Major Subordinate Command (MSC) and district Quality Management Plans? b. Does it state that ATR will be conducted or managed by the lead PCX?	EC 1165-2-209 Para 8a EC 1165-2-209 Para 9c(1)	a. Yes ☒ No ☐ b. Yes ☒ No ☐

c. Does it state whether IEPR will be performed? *Will IEPR be performed? Yes ☒ No ☐* d. Does it provide a defensible rationale for the decision on IEPR? e. Does it state that IEPR will be managed by an Outside Eligible Organization, external to the Corps of Engineers?	EC 1165-2-209 Para 7a EC 1165-2-209 Para 7a EC 1165-2-209 Para 11c	c. Yes ☒ No ☐ d. Yes ☒ No ☐ e. Yes ☒ No ☐ n/a ☐ **Comments:**
4. Does the RP explain how ATR will be accomplished?	EC 1165-2-209 Para 9 & Appendix C	Yes ☒ No ☐
a. Does it identify the anticipated number of reviewers? b. Does it provide a succinct description of the primary disciplines or expertise needed for the review (not simply a list of disciplines)? c. Does it indicate that ATR team members will be from outside the home district? d. Does it indicate that the ATR team leader will be from outside the home MSC? e. Does the RP state that the lead PCX is responsible for identifying the ATR team members and indicate if candidates will be nominated by the home district/MSC? f. If the reviewers are listed by name, does the RP describe the qualifications and years of relevant experience of the ATR team members?* **Note: It is highly recommended to put all team member names and contact information in an appendix for easy updating as team members change or the RP is updated.*	EC 1165-2-209 Appendix B Para 4f EC 1165-2-209 Appendix B Para 4g EC 1165-2-209 Para 9c(1)(a) EC 1165-2-209 Para 9c EC 1165-2-209 Para 9c(1) EC 1165-2-209 Appendix B Para 4k(5)	a. d. Does it indicate the IEPR will address all the underlying planning, safety assurance, engineering, economic, and environmental analyses, not just one aspect of the project?	EC 1165-2-209 Para 11a	d. Yes ☒ No ☐ **Comments** IEPR is required.
6. Does the RP address peer review of sponsor in-kind contributions?		Yes ☐ No ☒
a. Does the RP list the expected in-kind contributions to be provided by the sponsor? b. Does it explain how peer review will be accomplished for those in-kind contributions?	EC 1165-2-209 Appendix B Para 4j	a. Yes ☐ No ☐ b. Yes ☐ No ☐ n/a ☒ **Comments:**
7. Does the RP address how the peer review will be documented?		Yes ☒ No ☐
a. Does the RP address the requirement to document ATR and IEPR comments using DrChecks?	EC 1165-2-209 Para 7d	a. Yes ☒ No ☐
b. Does the RP explain how the IEPR will be documented in a Review Report?	EC 1165-2-209 Para 7a	b. Yes ☒ No ☐ n/a ☐
c. Does the RP document how written responses to the IEPR Review Report will be prepared?	EC 1165-2-209 Para 7d(2)	c. Yes ☒ No ☐ n/a ☐
d. Does the RP detail how the district/PCX will disseminate the final IEPR Review Report, USACE response, and all other materials related to the IEPR on the	EC 1165-2-209 Para 7d(2)(a)	d. Yes ☒ No ☐ n/a ☐

internet and include them in the applicable decision document?		**Comments:** IEPR will be performed
8. Does the RP address Policy Compliance and Legal Review?	EC 1165-2-209 Appendix C Para 3a	Yes ☒ No ☐ **Comments:**
9. Does the RP present the tasks, timing and sequence (including deferrals), and costs of reviews?	EC 1165-2-209 Appendix B Para 4c	Yes ☒ No ☐
a. Does it provide a schedule for ATR including review of the Feasibility Scoping Meeting (FSM) materials, Alternative Formulation Briefing (AFB) materials, draft report, and final report? b. Does it include interim ATR reviews for key technical products? c. Does it present the timing and sequencing for IEPR? d. Does it include cost estimates for the peer reviews?	EC 1165-2-209 Appendix C Para 3g(3) EC 1165-2-209 Appendix C Para 3g(3)	a. Yes ☒ No ☐ b. Yes ☒ No ☐ c. Yes ☒ No ☐ n/a ☐ d. Yes ☒ No ☐ **Comments:**
10. Does the RP indicate the study will address Safety Assurance factors? Factors to be considered include: • Where failure leads to significant threat to human life • Novel methods\complexity\ precedent-setting models\policy changing conclusions • Innovative materials or techniques • Design lacks redundancy, resiliency of robustness • Unique construction sequence or acquisition plans • Reduced\overlapping design construction schedule	EC 1165-2-209 Appendix E	**Yes** ☐ **No** ☐ **n/a** ☒ **Comments:** This is neither a FRM or Storm Damage Reduction Project
11. Does the RP address model certification requirements?	EC 1165-2-209 Appendix B Para 3a	Yes ☒ No ☐
a. Does it list the models and data anticipated to be used in developing recommendations (including mitigation models)?	EC 1165-2-209 Appendix B Para 4i	a. Yes ☒ No ☐

b. Does it indicate the certification/approval status of those models and if certification or approval of any model(s) will be needed? c. If needed, does the RP propose the appropriate level of certification/approval for the model(s) and how it will be accomplished?	EC 1165-2-209 Appendix C Para 3k(1) EC 1165-2-209 Appendix C Para 3k(1)	b. Yes ☒ No ☐ c. Yes ☒ No ☐ n/a ☐ **Comments:**
12. Does the RP address opportunities for public participation?		Yes ☒ No ☐
a. Does it indicate how and when there will be opportunities for public comment on the decision document? b. Does it indicate when significant and relevant public comments will be provided to reviewers before they conduct their review? c. Does it address whether the public, including scientific or professional societies, will be asked to nominate potential external peer reviewers? d. Does the RP list points of contact at the home district and the lead PCX for inquiries about the RP?	EC 1165-2-209 Appendix B Para 3a EC 1165-2-209 Appendix B Para 4e EC 1165-2-209 Appendix B Para 4h EC 1165-2-209 Appendix B Para 4a	a. Yes ☒ No ☐ b. Yes ☒ No ☐ c. Yes ☐ No ☒ d. Yes ☒ No ☐ **Comments:** c. External Peer Review is required
13. Does the RP address coordination with the appropriate Planning Centers of Expertise?	EC 1165-2-209 Appendix D Para 3	Yes ☒ No ☐
a. Does it state if the project is single or multi-purpose? Single ☒ Multi ☐ List purposes: Deep Draft Navigation b. Does it identify the lead PCX for peer review? Lead PCX: **DD** c. If multi-purpose, has the lead PCX coordinated the review of the RP with the other PCXs as appropriate?	 EC 1165-2-209 Appendix D Para 3c	a. Yes ☒ No ☐ b. Yes ☒ No ☐ c. Yes ☒ No ☐ n/a ☐ **Comments:**
14. Does the RP address coordination with the Cost Engineering Directory of Expertise (DX) in Walla Walla District for ATR of cost	EC 1165-2-209 Appendix D Para 3	Yes ☒ No ☐

estimates, construction schedules and contingencies for all documents requiring Congressional authorization?		
a. Does it state if the decision document will require Congressional authorization? b. If Congressional authorization is required, does the state that coordination will occur with the Cost Engineering DX?		a. Yes ☒ No ☐ b. Yes ☒ No ☐ n/a ☐ **Comments:**
15. Other Considerations: This checklist highlights the minimum requirements for an RP based on EC 1165-2-209. Additional factors to consider in preparation of the RP include, but may not be limited to: a. Is a request from a State Governor or the head of a Federal or state agency to conduct IEPR likely? b. Is the home district expecting to submit a waiver to exclude the project study from IEPR? c. Are there additional Peer Review requirements specific to the home MSC or district (as described in the Quality Management Plan for the MSC or district)? d. Are there additional Peer Review needs unique to the project study?	EC 1165-2-209 Appendix D Para 1b(3&4) EC 1165-2-209 Para 11d	**Comments:** a. Yes ☐ No ☒ b. Yes ☐ No ☒ **Comments:** IEPR will be performed c. Yes ☐ No ☒ d. Yes ☐ No ☒

REVIEW PLAN
FOR
Mouth of the Columbia River Jetties Major Rehabilitation
O&M

U.S Army Corps of Engineers

Portland District

July 16, 2010
(revised September 23, 2010 and October 21, 2011)

DRAFT

Table of Contents

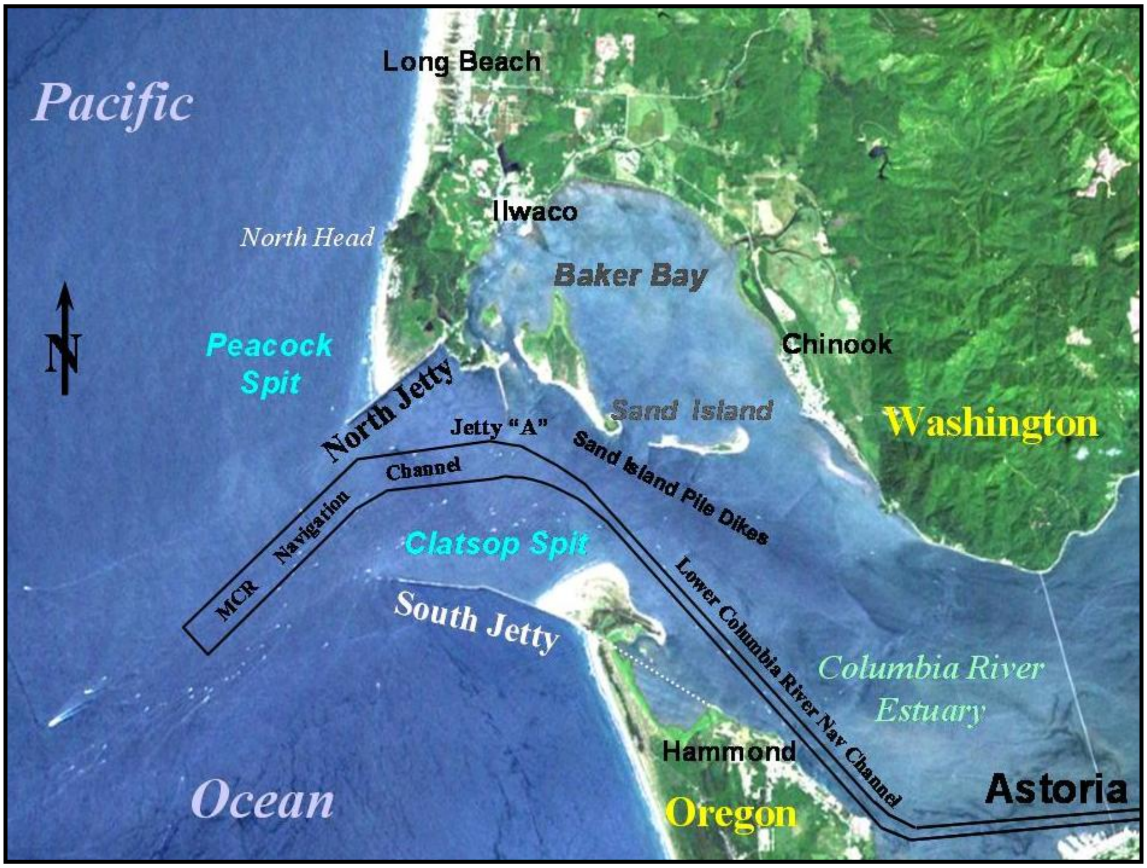
1. INTRODUCTION

The North Jetty and Jetty A are located in Pacific County, Washington, near Ilwaco and Long Beach on the Long Beach Peninsula (Figures 1 and 2). The North Jetty was completed in 1917. Jetty A, positioned on the south side of the North Jetty, was constructed in 1939 to a length of 1.1 miles. Jetty A was constructed to direct river and tidal currents away from the North Jetty foundation. The South Jetty is located in Clatsop County, Oregon near Warrenton/Hammond and Astoria. The initial 4.5-mile section of the South Jetty was completed in 1895, with a 2.4-mile extension completed in 1913. Jetty construction realigned the ocean entrance to the Columbia River, established a consistent navigation channel that was 40 feet deep across the bar, and significantly improved navigation through the MCR. Improvements made from 1930 to 1942 (including addition of Jetty A and Sand Island pile dikes) produced the present entrance configuration.

Prior to improvement in 1885, the tidal channels through the MCR shifted north and south between Fort Stevens and Cape Disappointment, a distance of about 5.5 miles. The controlling depth of dominant channel through the ebb tidal delta varied between 18 to 25 feet deep below MLLW. The ebb and flood tidal deltas at MCR entrance were distributed over a large area immediately seaward and upstream of the river mouth. Ships often had trouble traversing the Columbia River bar, the area in which the flow of the estuary rushes headlong into towering ocean waves. On many occasions, outbound ships had to wait a month or more until bar conditions were favorable for crossing. To make navigating through the MCR even worse, sailing ships had to approach either of the two natural channels abeam to the wind and waves. The natural channels often shifted widely within the course of several tidal cycles. At best, crossing the bar was dangerous. At worst, it was not possible.

Offshore of the MCR is the northeast Pacific Ocean. Inshore of the MCR is the Columbia River and estuary, the coastal outlet for a drainage basin of 250,000 square miles where the headwaters emanate from the western slope of the Rocky Mountains. The course of the Columbia River is 1,210 mile long, dropping over 2,600 feet from its Canadian headwaters to the sea. The river accounts from 60% in the winter to 90% in the summer of the total freshwater discharge into the ocean between the Canadian border and San Francisco, California. The Columbia River estuary is the largest fluvial dominate estuary in the Pacific Northwest. Its upriver limit, defined in terms of salt water intrusion, varies from river mile (RM) 28 to 38 and is a function of fluvial flow and sequencing of the tidal cycle. Current reversal due to tide can occur as far inland as RM 70. Tidal effects (fluctuation of water surface elevation) extend upriver to Bonneville Dam (RM 145).

Figure 1. Location of the Jetty System at the MCR



The 6-mile long deep-draft navigation channel at the MCR has become the ocean gateway for navigation access to and from the 500-mile long Columbia/Snake River inland navigation system. It is a critical regional and national gateway linking agricultural, mineral and goods production across the Northwest, Mountain, Midwest, and East Coast states to growing markets in the Pacific Rim. Economies of many states rely on the trade and commerce that flows up and down the system. Each year, ocean-going vessels on the Columbia River carry about 40 million tons of cargo with an estimated value of $17 billion on an annual basis. More than 12,000 commercial vessels and 100,000 recreational/charter vessels navigate through the MCR annually. According to the Center for Economic Development and Research,[1] the Columbia/Snake River navigation system is the #1 export gateway for the Nation's wheat and barley exports. It is also a primary paper/paper products export gateway; bulk minerals export gateway; and automobile import gateway for the West Coast. Also, marine traffic passing the entrance of the Columbia River is projected to increase by 35% from 32 million tons (2003) to 43 million tons by 2020.

South Jetty

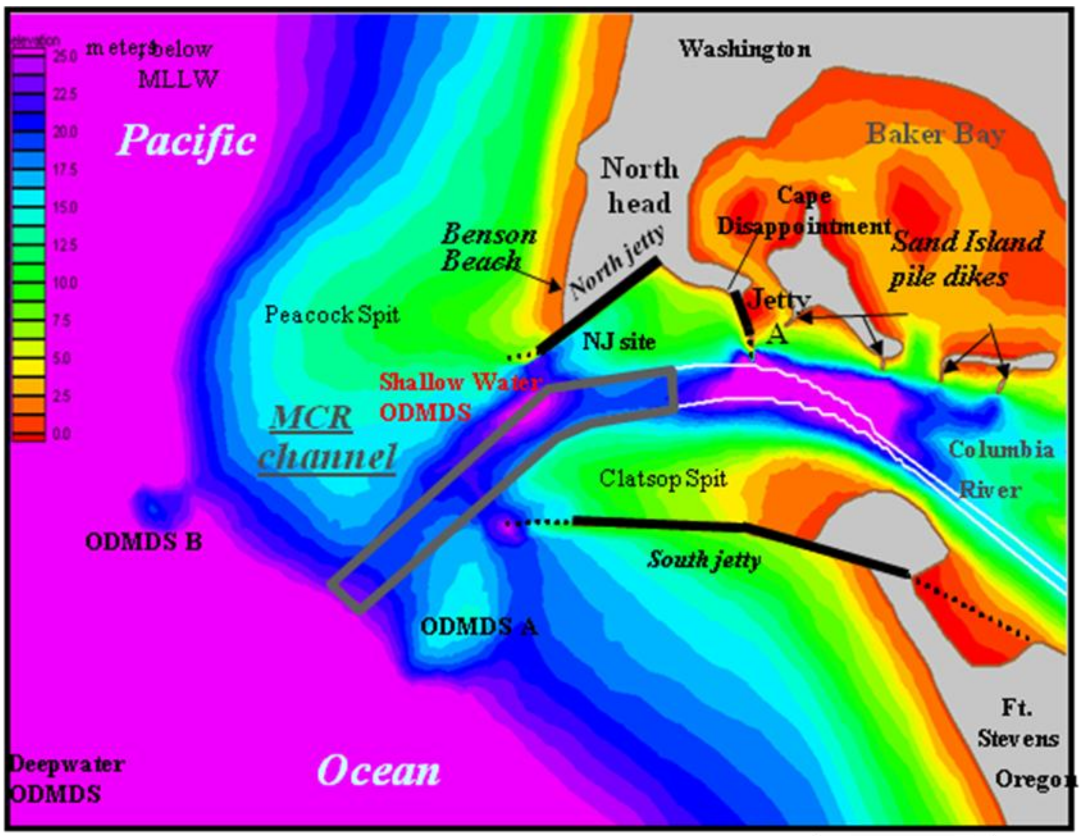
Jetty A

North Jetty

2. PROJECT BACKGROUND

The jetties at the MCR were constructed on massive tidal shoals and these shoals have been changing since the time of jetty construction. The longevity of the jetties is tied to the stability of the shoals on which the jetties were built, and the stability of the shoals is now a function of the jetties. The jetties and shoals act as integrated units to confine tidally driven circulation through the MCR and maintain the present channel configuration. Figure 3 illustrates the extensive underwater shoal system at the MCR.

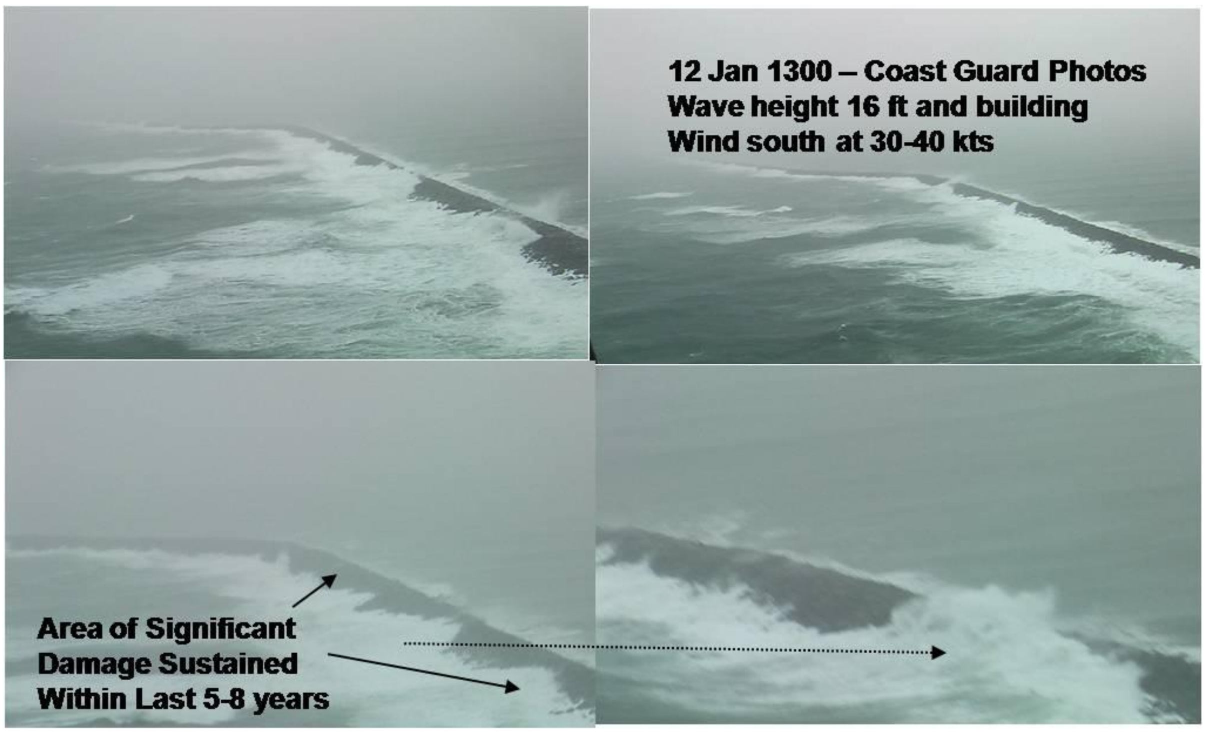
Figure 3. Bathymetry and Underwater Shoal System at the MCR



Through phased jetty construction (1885-1939) and the associated response of MCR morphology, each project feature at the MCR now is dependent on the other, both in terms of structural integrity and project feature functional performance. Severe deterioration of any of these features can jeopardize the MCR federal navigation channel and adversely affect the other structures. Should the North Jetty experience substantial deterioration from its present condition, the navigation channel, South Jetty, Jetty A, and ultimately the Sand Island pile dikes would be negatively affected. A similar scenario would likely occur if the South Jetty experienced substantial deterioration from its present condition. In this regard, the project features at the MCR are interrelated.

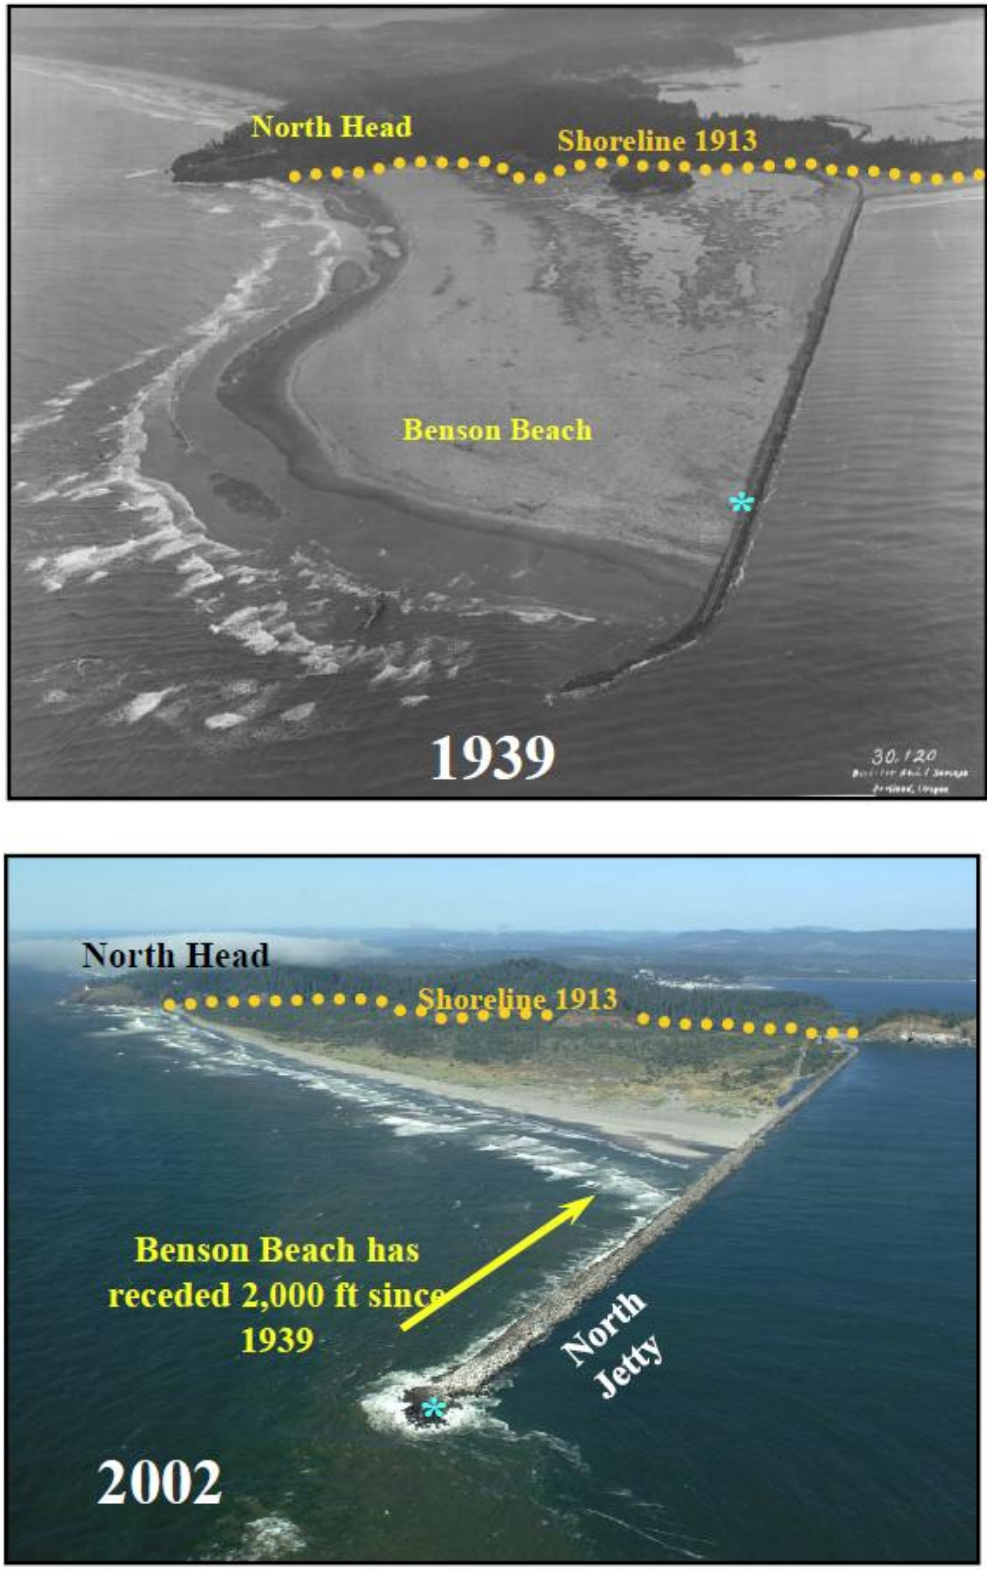
Structural degradation of the +100-year old MCR jetty system has accelerated in recent years because of increased storm activity and loss of sand shoal material upon which the jetties are constructed (Figure 4 shows waves attacking the South Jetty). In addition, beaches on the ocean sides of the North and South jetties, which formed as a result of jetty construction, have been receding gradually over the years, exposing previously protected jetty sections at the beach line to storm waves (Figure 5 shows Benson Beach recession at North Jetty).

Figure 4. Wave Action on South Jetty



The orientation of the shoals/spits at the MCR has arisen due to waves and currents; the morphology and coastal processes at the MCR are linked. Eddies that form within the MCR arise due to the interaction of flow with the jetties and the morphology greatly influences flow and shoaling within the federal navigation channel. The littoral dynamics north and south of the MCR are drastically different than at "open coast" areas away from the entrance. Depending on the regional wind field, the "coastal current" up-drift and down-drift from the MCR can attain speeds of 3 feet/second. As the tidal shoals continue to recede (erode), the MCR jetties will be exposed to larger waves and more vigorous currents.

Figure 5. Shoreline Response North of North Jetty



Despite intermittent repair and partial rehabilitation efforts, all of the MCR jetties are currently in a significantly deteriorated condition (Figures 6 and 7). Intermittent repairs were conducted in 2005 on the North Jetty and in 2006 and 2007 on the South Jetty. The last partial rehabilitation on the North Jetty was conducted in 1964 and addressed 17% of its length; the last partial rehabilitation on the South Jetty was conducted in 1982 and addressed 25% of its length; and the last partial rehabilitation on Jetty A was conducted in 1961 and addressed 56% of its length. The lengths of the North and South jetties, which have never been repaired since original construction, are 55% and 36%, respectively. The jetties continue to recede back from their original length. The head positions for the South and North jetties and Jetty A are currently shorter than authorized lengths by 6,200 feet, 2,120 feet, and 900 feet, respectively. Due to the interaction of wave patterns and currents with the jetty configuration, the shorter jetty lengths can increase underwater shoal erosion, influence shoreline position adjacent to the jetties, and alter the forcing climate at the project.

Figure 6. South Jetty Trunk Damage

Figure 7. North Jetty Damage Areas

Progressive damages to one of the jetties could result in a significant breach which can trigger an emergency repair to the jetty, rapid infill into the navigation channel, and emergency dredging activities. The current major rehabilitation approach for the MCR jetty system focused on adequately defining the larger processes affecting the jetty system, and then describing the jetty system reliability over time. Consequences evaluated included frequency and costs of future jetty repairs, as well as potential impacts to dredging and navigation. Each alternative adds additional elements of either process stabilization or above or below water cross section stabilization, as well as varying degrees of cross section reliability improvement.

In summary, taking no action to rehabilitate the MCR jetties to extend the functional life would result in further deterioration of the structures and the sand shoals upon which they rest, and would increase the likelihood of a jetty breach. Recent interim jetty repairs have addressed immediate critical needs. However, additional modifications and repairs to the jetties are necessary to address critical near- and long-term needs and to reduce the potential for emergency repairs, emergency dredging, and impacts to the Columbia-Snake River inland navigation system.

3. STUDY PURPOSE

Budget guidance [Budget Engineer Circular (EC) 11-2-199, dated 31 March 10] defines major rehabilitation based on these thresholds: "The work will extend over at least two full construction seasons and will require at least $6.6 million in outlays. For inland waterways projects, the reliability threshold will be $14 million." The work on all three of the MCR jetties fits the definition of major rehabilitation and therefore, this report is prepared using that guidance.

This evaluation was undertaken to address problems related to the structural stability of the MCR jetty system in order to extend their functional life and maintain deep-draft navigation.

This Review Plan (RP) outlines the review plan as required by EC 1105-2-410. This RP supplements the Project Management Plan (PMP). There are three levels of peer review required for this Study: District Quality Control (DQC), Agency Technical Review (ATR), and Independent External Peer Review (IEPR) based on the scale, impacts, and cost of this project.

Engineer Circular (EC) 1105-2-410 (Circular) dated 22 Aug 2008 "Review of Decision Documents" provides the procedures for improving the quality and credibility of U.S. Army Corps of Engineers (USACE) decision documents through an independent review process. It complies with Section 515 of Public Law 106-554 (referred to as the "Data Quality Act "); and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Bulletin. It also provides guidance for the implementation of Section 2034 of WRDA 2007 (P.L. 110-114). This Circular also presents a framework for establishing the appropriate level and independence of review and detailed requirements of review documentation and dissemination.

A. Requirements. All decision documents and their supporting analyses will undergo DQC and ATR and may also require IEPR, to "ensure the quality and credibility of the government's scientific information", in accordance with this circular and the quality management procedures of the responsible command. The Circular addresses review of the decision document as it pertains to both approaches and planning coordination with the appropriate Center. The Circular also requires that DrChecks (https://www.projnet.org/projnet/) be used to document all ATR and IEPR comments, responses, and associated resolutions accomplished.

The types of technical review are provided below and have been redefined and renamed for consistency with recent legislation and to establish a more comprehensive lexicon. This Circular uses the terms "home district" or "home MSC" to refer to the office that has been assigned responsibility for a study or project and whose commander will sign any recommendations or decision document. Where studies are conducted by non-Federal interests, the "home district" will be the district which has the area of responsibility that contains the proposed project.

(1) **District Quality Control** (DQC). DQC is the review of basic science and engineering work products focused on fulfilling the project quality requirements defined in the Program Management Plan (PMP). It is managed in the home district and may be conducted by staff in the home district as long as they are not doing the work involved in the study, including contracted work that is being reviewed. Basic quality control tools include a Quality Management Plan providing for seamless review, quality checks and reviews, supervisory reviews, Project Delivery Team (PDT) reviews, etc. Additionally, the PDT is responsible for a complete reading of the report to assure the overall integrity of the report, technical appendices and the recommendations before approval by the District Commander. It is expected that the MSC/District quality management plans address the conduct and documentation of this fundamental level of review. DQC is not covered by this Review Plan.

(2) **Agency Technical Review** (ATR). ATR (which replaces the level of review formerly known as Independent Technical Review) is an in-depth review, managed within USACE, and conducted by a qualified team outside of the home district that is not involved in the day-to-day production of a project/product. The purpose of this review is to ensure the proper application of clearly established criteria, regulations, laws, codes, principles and professional practices. The ATR team reviews the various work products and assures that all the parts fit together in a coherent whole. ATR teams will be comprised of senior USACE personnel (Regional Technical Specialists (RTS), etc.), and may be supplemented by outside experts as appropriate. To assure independence, the leader of the ATR team shall be from outside the home MSC.

(3) **Independent External Peer Review** (IEPR). This is the most independent level of review, and is applied in cases that meet certain criteria where the risk and magnitude of the proposed project are such that a critical examination by a qualified team outside of USACE is warranted. The criteria for application of IEPR include, but are not limited to (1) the total project cost exceeds $45 million; (2) there is a significant threat to human life; (3) it is requested by a State Governor of an affected state; (4) it is requested by the head of a Federal or state agency charged with reviewing the project if he/she determines the project is likely to have a significant adverse impact on resources under the jurisdiction of his/her agency after implementation of proposed mitigation (the Chief has the discretion to add IEPR under this circumstance); (5) there is significant public dispute regarding the size, nature, effects of the project; (6) there is significant public dispute regarding the economic or environmental cost or benefit of the project; (7) cases where information is based on novel methods, presents complex challenges for interpretation, contains precedent-setting methods or models, or presents conclusions that are likely to change prevailing practices; or (8) any other circumstance where the Chief of Engineers determines IEPR is warranted. IEPR may be appropriate for feasibility studies; reevaluation studies; reports or project studies requiring a Chiefs Report, authorization by Congress, or an EIS; and large programmatic efforts and their component projects. IEPR is managed by an outside eligible organization (OEO) that is described in Internal Revenue Code Section 501(c)(3), is exempt from Federal tax under

section 501(a), of the Internal Revenue Code of 1986; is independent; is free from conflicts of interest; does not carry out or advocate for or against Federal water resources projects; and has experience in establishing and administering IEPR panels. The scope of review will address all the underlying planning, engineering, including safety assurance, economics, and environmental analyses performed, not just one aspect of the project.

(4) **Policy and Legal Compliance Reviews** In addition to the technical reviews described above, decision documents will be reviewed throughout the study process for their compliance with law and policy. Guidance for policy and legal compliance reviews is addressed further in Appendix H, ER 1105-2-100. The technical review efforts addressed in this Circular are to augment and complement the policy review processes by addressing compliance with published Army policies pertinent to planning products, particularly policies on analytical methods and the presentation of findings in decision documents. DQC and ATR efforts are to include the necessary expertise to address compliance with published planning policy.

(5) **Planning Center of Expertise (PCX) Coordination.** The Circular outlines PCX coordination in conjunction with preparation of the review plan. Districts should prepare the plans in coordination with the appropriate PCX and appropriate consultation with the allied Communities of Practice. The MSC Commander's approval of the review plan is required to assure that the plan is in compliance with the principles of this Circular and the MSC Quality Management Plan (ER 5-1-11). The review plans must anticipate and define the appropriate level of review. All reviews are expected to be completed and documented before the District Commander signs the report.

The PDT is presented in Appendix 1. The project manager, Eric Bluhm, is the main point of contact at Portland District for more information about this project and the review plan.

4. PROPOSED PLANNING MODELS

The MCR SRB model was developed to be a statistical tool to assist engineers and project managers in determining the most cost-effective and reliable method of maintaining and repairing the MCR jetties into the future. The SRB model was written for use in MATLAB® (The Mathworks Inc. 2009). A detailed description of the SRB model is provided in Appendices A2 and A3. Described below is a general overview of the intent, operation, and organization of the model, the coastal engineering functions, and an overview of the model inputs and outputs.

MCR SRB Model Intent

The general intent of the MCR SRB model is to predict the lifecycle costs of repairing and maintaining the MCR jetties based on several repair and maintenance alternative plans. The ultimate objective is to utilize the predicted lifecycle cost ranges and reliabilities computed from each modeled plan to select the option that best balances least cost with highest reliability. The SRB model provides estimates, not definitive answers and is useful in comparing alternatives, costs and consequences but is not the only basis for plan selection. At the foundation of the model is a Monte Carlo simulation which comprises numerous model runs (in the hundreds), each with varying random parameter values. The model, therefore, relies heavily on statistical analysis. Random variation of specific parameters is necessary due to the uncertainty involved in predicting the future demand on, and resultant response of, the jetty structures. Also through this analysis, it is possible to observe the parameters that are most sensitive to random variation and have the largest impacts on lifecycle costs and/or reliability. If the impacts of these parameters are understood and their variation can be controlled to a certain degree, it is logical to conclude that the lifecycle costs can likewise be managed to a similar degree.

MCR SRB Model Operation

The SRB model can be operated in two distinct manners, as a *hindcast* model or a *forecast* model. The hindcast mode incorporates historical jetty geometries (e.g., cross-sectional elevations and widths), costs, and other relevant information from the actual repairs that occurred to each structure since original construction (or since a specified historical date in the case of the South Jetty). Generally, if there is good agreement between modeled and measured data, then the model has good skill (predictability) and is deemed to be performing well. In calibrating the SRB model, *historical* costs and repair schedules were compared to *modeled* costs and schedules. Based on analysis of modeled results (i.e., plots of costs and repair schedules), the hindcast predictions for the MCR jetties are judged to have good model skill.

The hindcast model results are also used to initialize the model for operation in the forecast mode. In the forecast mode, the SRB model predicts structural damages (based on randomized storm conditions), implements repairs and rehabilitations, and calculates dredging and stone quantities over an anticipated jetty lifecycle. The forecasting procedure is similar to the hindcast procedure in the model. For simplicity, only the model forecasting procedures will be described below, but the general methods are essentially equivalent.

Typical simulation using the SRB model is as follows:

1. Simulate Structure’s Previous Life Cycle – Hindcast: Calibrate model to ensure the model replicates observed life-cycle quantities and timing and location of observed repairs. Key inputs include actual repair history, location, timing, and frequency.
2. Simulate Future Life Cycle – Forecast: Establish base condition to evaluate potential maintenance/rehabilitation scenarios against. A base condition is selected that is most likely to be implemented in a “non-intervention” framework.
3. Simulate Future Life Cycle – Alternative Analysis Forecast: Evaluate alternatives by life-cycle dredging and stone quantities and other metrics.

4. Select the alternative which achieves best reliable life-cycle performance.

For this project, the SRB model provides estimates, not definitive answers and is useful in comparing consequences for alternatives, but is not the only basis for plan selection.

The SRB model was used to hindcast the life-cycle performance of each jetty from initial construction (early 1910s) to the present (2010). Accurate hindcasting of jetty performance served as a basis for model verification. Metrics provided by the SRB model, which were used to evaluate life-cycle performance include:

- Jetty cross section evolution;
- Time-varying structural and functional reliability and residual risk;
- Jetty repair occurrence – expected frequency and location of jetty repairs;
- Jetty breach occurrence – expected frequency and location of jetty breaches;
- Potential for loss of jetty function to impact navigation function of the inlet; and
- Jetty end-state condition.

The SRB model was used in forecast mode to formulate an optimal plan for rehabilitating each jetty, predicated on the need to minimize life-cycle costs or maximize.

5. REVIEW SCHEDULE

ATRs will be conducted for all major GI phase documents (i.e, without-project report, feasibility scoping documents, plan selection report, and Draft FR/EA) and major engineering and scientific documents products (e.g., cultural resources overview, geomorphology report, and programmatic biological assessment). The review schedule is included in the Project Management Plan (PMP) and will be updated as reviews are scheduled.

Review	**Date**
EA out for public Review	February 2010
DQC of Main Report and Appendices	July/August 2010
ATR of Main Report/Appendices	23 August 2010
Draft Major Rehab Report complete	31 October 2010
IEPR completed	7 April 2011
SRB Model disapproved by HQUSACE	30 April 2011
Moffatt & Nichol: SRB model revised	30 March 2012
SRB model certified by ATR lead	30 March 2012
SRB model approved by HQUSACE	27 April 2012
DQC draft Major Rehab Report (MRR)	4 May 2012
Final MRR sent to NWD for approval	9 May 2012
Major Rehabilitation Report approved	8 June 2012

6. INDEPENDENT EXTERNAL PEER REVIEW (IEPR)

An independent external peer review was completed on the draft final main report and EA. The IEPR focused on the logic and understandability of the Planning and NEPA process and the analysis and rationale of the selected alternative for each jetty. The review panel was composed of individuals with expertise in, specific to the Pacific Northwest, coastal engineering, modeling (in Matlab), environmental compliance, cost engineering and economics. The entire decision document and EA with appendices was provided to the IEPR team on searchable CD. The IEPR was be done in DrChecks.

The IEPR was conducted by a contractor and managed by the Deep-draft center of expertise (DDNPCX). The DDN-PCX followed the process established in EC 1105-2-410 in managing the IEPR. The IEPR Team member disciplines can be found in Appendix 3.

The information from the IEPR was documented in a Report. This IEPR Report included the formal USACE responses and position on all IEPR comments. The information from the Report was included in the decision-making process.

The IEPR panel met with the study PDT and the public to determine areas of controversy in the feasibility report, and reviewed the written feasibility report documentation and files, including the technical appendices. The external peer review team will ensured:

- Scientific data used in the study was accurate and complete.
- Modeling methods used were pertinent to the type of study results required, and sound modeling methodology was used
- The analysis contained clearly justified and valid assumptions
- concepts, features, analytical methods, analyses, and details are appropriate, fully coordinated, and correct
- Problems/issues are properly defined and scoped
- Conclusions and recommendations are reasonable and justified.

The cost for the IEPR was approximately $250,000.

7. PUBLIC REVIEW OPPORTUNITIES

The public has been provided the opportunity to comment in Feb. 2010 on the EA as part of NEPA compliance. If the selected plans change significantly as a result of significant changes to the selected plan causing great environmental impacts, another draft of the EA will be posted for 30-day review by the public with a 15-day comment window.

8. ANTICIPATED NUMBER OF REVIEWERS

The current ATR plan included least six reviewers from outside of the Northwestern Division. This number was based on the disciplines required to develop the draft main report and EA.

9. PRIMARY DISCIPLINES & EXPERTISE NEEDED FOR ATR

The disciplines and expertise required for the ATR team are presented in Appendix 2.

The Agency Technical Review Team was selected on the basis of having the proper knowledge, skills, and experience necessary to perform the task and their lack of affiliation with the development of the main report, EA, and associated appendices. The review team will be developed by the Deep-Draft Navigation Center of Expertise to ensure that the technical work and products from each discipline achieve a quality product. The ATR was completed through DRCHECKS.

Technical review used appropriate analytical methods for each technical area. Technical review relied on periodic technical review team meetings to discuss critical plan formulation or other project decisions, and on the review of the written feasibility report documentation and files. Independent technical review ensured that:

- the draft main report and EA is consistent with current criteria, procedures and policy
- clearly justified and valid assumptions that are in accordance with established guidance and policy have been utilized, with any deviations clearly identified and properly approved
- concepts, features, analytical methods, analyses, and details are appropriate, fully coordinated, and correct
- problems/issues are properly defined and scoped
- conclusions and recommendations are reasonable and justified.

Funding in the amount of $100,000 was budgeted for Agency Technical Review.

Upon disapproval of the SRB model on 30 April 2011, the PDT engaged an AE firm to revise the model. Subsequently, the ATR lead reviewed and approved the revised model prior to review and approval by HQUSACE. Since the assumptions and plan selection process remained consistent from the draft to final Major Rehabilitation Report, another ATR and IEPR was not conducted.

APPENDIX 1: PROJECT DELIVERY TEAM

Discipline	Name	Office/Agency
Project Manager	Eric Bluhm	CENWP-PM-FP
Program Manager (O&M)	Tracy Williams	CENWP-PM-PD
Program Analyst	Tanya Young	CENWP-PM-PD
Plan Formulation	Laura Hicks	CENWP-PM
Environmental Coordinator	Jody Marshall	CENWP-PM-E
Environmental Compliance	Barbara Cisneros	CENWP-PM-E
Civil Design/Technical Lead	Mark Brodesser	CENWP-EC-DC
Survey/ CADD Mapping/GIS	Doug Swanson	CENWP-EC-TG
Geotechnical	Jeremy Britton	CENWP-EC-DC
Hydraulics & Hydrology	Cindy Thrush	CENWP-EC-HY
Hydraulics & Hydrology	Rod Moritz	CENWP-EC-HY
Economic Evaluation	Pat McCrae	CENWP-PM-FE
Cost Engineering	Phil Ohnstad	CENWP-EC-CC

NWP RESPONSES TO NWD REVIEW COMMENTS FOR THE MCR JETTIES MAJOR REHABILITATION REPORT

June 15, 2012

BLUF (Bottom Line Up Front)

(1) NWD Comment (5/31/12): There has not been an ATR review on the base condition, evaluation, and recommendations as currently described in the report.

NWP Response (6/7/12): Concur. The ATR lead Robert Patev (CEIWR-RMC-ED) has agreed to conduct such a review in DrChecks along with ATR team members Alan Jeffries, a coastal engineer (CEPOA-EN-CW-HH) and Kevin Knight, an economist (CEIWR-GW). The plan is to ATR the May 2012 report to specifically review the base condition, the evaluation process and recommendations. Upon resolution of NWD comments, we will have only the ATR Lead, Bob Patev, recheck the final report.

Comment resolved: conditional upon ATR certification of report, 6/15/12

---

(2) NWD Comment (5/31/12): There was a premature screening out of alternative based solely on estimated averaged annual costs when the costs are virtually indistinguishable. An explanation of the screening process and evaluation factors should be summarized in the report.

NWP Response (6/7/12): Concur. The following information will be incorporated into Chapter 4:

The Corps began looking at applying a system approach to the MCR entrance in 1999. Throughout FY 06-10, NWP considered where the end of each of three jetties should be at the mouth of the Columbia River and developed three jetty length options:

- rebuild the jetties to their authorized lengths
- rebuild the jetties to the midpoint between the authorized length and the existing jetty end station
- rehabilitating the jetty to the current end station

NWP has considered major alternatives to the authorized cross-section that included designs that stayed on the existing footprint and those that went off the existing footprint, including realigning the entire system.

Alternatives that extended the jetty lengths significantly beyond the existing end station or reconstructed the jetties off the existing footprint were deemed infeasible. Plans that extended beyond the authorized length or off the authorized footprint were outside the authority for this project.

In FY 2010-11, a 90% draft of the MRR underwent District Quality Control (DQC) and Agency Technical Review (ATR). The underlying tenets of that report included a base condition involving a fix-as-fails approach where each jetty was allowed to degrade as low as 20% of the originally authorized cross-section remaining above MLLW -5, resulting in forecasted breaches. The hypothetical breaches would release material into the navigation channel, leading to emergency dredging. Breaches were forecasted to primarily occur in the winter, thus emergency dredging was high-risk and very expensive, and reliability of the navigational channel became questionable. Moreover, potential breach volumes entering the navigation channel were difficult to predict. In an attempt to model these effects, the SRB model code became more complex as the analysis was developed and the timing of the runs became very long and the economics was embedded within the model code. NWP also developed a qualitative numeric scoring of alternatives that included several factors beyond average annual cost.

The IEPR was conducted from December 2010 through April 2011. At the same time, the SRB model underwent substantial review, including ATR approval and DDN-PCX model certification in January 2011. This documentation was then forwarded to HQUSACE for final approval where it was disapproved in June 2011 because the IEPR panel raised concerns about the predicted frequency and severity of breaching and sediment transport in the base condition.

After consultation with NWD, it was decided that an MMR should be produced for the most critical portions of the North Jetty for inclusion in the FY 2013 budget submission. Therefore, the lagoon fill between STA 20 to 60 and critical repairs between STA 86 to 99 were removed from the MRR alternatives and included in the revised base condition. These repairs were deemed high-risk and were assumed to occur before the major rehab actions.

NWP decided to revise the SRB model, MRR and appendices per IEPR comments and hired Moffatt & Nichol, a coastal engineering consultant. The A/E task order emphasized improving the model code; showing compliance with current technology and Corps policy; providing additional documentation; improving practicality with data inputs and outputs; and user manual; and clearly identifying the use and limitations of the model consistent with EC 1105-2-412.

Due to the level of construction and high mobilization costs, the revised FY 12 base condition—identified as an interim-repair approach—was developed to replace the FY 11 "fix-as-fails" approach. The new base condition assumes the upper portion of the jetty is allowed to be degraded until approximately 35% of the cross-section is remaining prior to repair action being initiated. This change in the base condition allows for repair actions to take place prior to a breach event, and thereby eliminates breaching and sediment transport through the jetty, affecting the navigational channel and significantly reduces winter emergency dredging.

The economics analysis is now outside the model in a post-process spreadsheet. The code has been modularized and simplified so that there is one code for all three jetties. The user's manual provides enough detail for a knowledgeable coastal engineer to run the model. These changes improved the transparency of the model's sub-routines, dependant and independent variables, and damage functions leading to the ultimate approval of the model on 27 April 2012.

The above series of events resulted in a change in the selected plans for the three jetties.

ER 1105-2-100, Appendix G (pp. 7-8), states: "Identification of the NED plan is to be based on consideration of the most effective plans for providing different levels of output or service. Where two cost-effective plans produce no significantly different levels of net benefits, the less costly plan is to be the NED plan, even though the level of outputs may be less."

It is important to note that the purpose of the authorized project is to maintain a reliable, functioning, deep-draft navigation channel through the Columbia River entrance. It is not to compare the structural components of each of the alternatives so that if two alternatives still result in no impact to the navigation channel, their benefit is treated as the same. Therefore, the alternatives were evaluated based on least cost as long as they still provided for a usable channel.

In addition, the price of jetty stone and the quantity needed to construct the spur groins proposed outweighed the predicted benefit of repeated maintenance. This assumption will be monitored in the recommended plan throughout time and if foundation conditions deteriorate, threatening or affecting the jetty's stability, this decision will be revisited in the future.

Comment resolved: IRC 6/14

---

(3) NWD Comment (5/31/12): There is not a concise description of the recommended plan. Additionally, there is a lack of clarity of alternative analysis (Chapter 4) in terms of inclusion of metrics into the Average Annual Cost (AAC), in particular constructability and structural and functional reliability as requested in an NWD Memo dated 30 June 2010.

NWP Response (6/7/12): Concur. The following text is proposed to be added to the report to Chapter 4 to address this comment:

The Corps began looking at applying a system approach to the MCR entrance in 1999. Throughout FY 06-10, NWP considered where the end of each of three jetties should be at the mouth of the Columbia River and developed three jetty length options:

- rebuild the jetties to their authorized lengths
- rebuild the jetties to the midpoint between the authorized length and the existing jetty end station
- rehabilitating the jetty to the current end station

NWP has considered major alternatives to the authorized cross-section that included designs that stayed on the existing footprint and those that went off the existing footprint, including realigning the entire system.

Alternatives that extended the jetty lengths significantly beyond the existing end station or reconstructed the jetties off the existing footprint were deemed infeasible. Plans that extended beyond the authorized length or off the authorized footprint were outside the authority for this project.

In FY 2010, a 90% draft of the MRR underwent District Quality Control (DQC) and Agency Technical Review (ATR). The underlying tenets of that report included a base condition involving a fix-as-fails approach where each jetty was allowed to degrade as low as 20% of the originally authorized cross-section remaining above MLLW -5, resulting in forecasted breaches. The hypothetical breaches would release material into the navigation channel, leading to emergency dredging. Breaches were forecasted to primarily occur in the winter, thus emergency dredging was high-risk and very expensive, and reliability of the navigational channel became questionable. Moreover, potential breach volumes entering the navigation channel were difficult to predict. In an attempt to model these effects, the SRB model code became more complex as the analysis was developed and the timing of the runs became very long and the economics was embedded within the model code. NWP also developed a qualitative numeric scoring of alternatives that included several factors beyond average annual cost.

The IEPR was conducted from December 2010 through April 2011. At the same time, the SRB model underwent substantial review, including ATR approval and DDN-PCX model certification in January 2011. This documentation was then forwarded to HQUSACE for final approval where it was disapproved in June 2011 because the IEPR panel raised concerns about the predicted frequency and severity of breaching and sediment transport in the base condition.

After consultation with NWD, it was decided that an MMR should be produced for the most critical portions of the North Jetty for inclusion in the FY 2013 budget submission. Therefore, the lagoon fill between STA 20 to 60 and critical repairs between STA 86 to 99 were removed from the MRR alternatives and included in the revised base condition. These repairs were deemed high-risk and were assumed to occur before the major rehab actions.

NWP decided to revise the SRB model, MRR and appendices per IEPR comments and hired Moffatt & Nichol, a coastal engineering consultant. The A/E task order emphasized improving the model code; showing compliance with current technology and Corps policy; providing additional documentation; improving practicality with data inputs and outputs; and user manual; and clearly identifying the use and limitations of the model consistent with EC 1105-2-412.

Due to the level of construction and high mobilization costs, the revised FY 12 base condition—identified as an interim-repair approach—was developed to replace the FY 11 “fix-as-fails” approach. The new base condition assumes the upper portion of the jetty is allowed to be degraded until approximately 40% of the cross-section is remaining prior to repair action being initiated. This change in the base condition allows for repair actions to take place prior to a breach event, and thereby eliminates breaching and sediment transport through the jetty, affecting the navigational channel and significantly reduces winter emergency dredging.

The economics analysis is now outside the model in a post-process spreadsheet. The code has been modularized and simplified so that there is one code for all three jetties. The user’s manual provides enough detail for a knowledgeable coastal engineer to run the model. These changes improved the transparency of the model’s sub-routines, dependant and independent variables, and damage functions leading to the ultimate approval of the model on 27 April 2012.

The above series of events resulted in a change in the selected plans for the three jetties.

ER 1105-2-100, Appendix G (pp. 7-8), states: "Identification of the NED plan is to be based on consideration of the most effective plans for providing different levels of output or service. Where two cost-effective plans produce no significantly different levels of net benefits, the less costly plan is to be the NED plan, even though the level of outputs may be less."

It is important to note that the purpose of the authorized project is to maintain a reliable, functioning, deep-draft navigation channel through the Columbia River entrance. It is not to compare the structural components of each of the alternatives so that if two alternatives still result in no impact to the navigation channel, their benefit is treated as the same. Therefore, the alternatives were evaluated based on least cost as long as they still provided for a usable channel.

In addition, the price of jetty stone and the quantity needed to construct the spur groins proposed outweighed the predicted benefit of repeated maintenance. This assumption will be monitored in the recommended plan throughout time and if foundation conditions deteriorate, threatening or affecting the jetty's stability, this decision will be revisited in the future.

NWD Response (6/14/12): Unfortunately the reviewer didn't clearly make the intended point. The response is good, but really more relevant to BLUF #3. The comments should have read "AAC should be reported to a defensible level of accuracy, presumably $millions. The NED plan would then be accurately portrayed as one of 3 or 4 of the lowest cost alternatives for the north and south jetties. Further screening of these NED plans could then be done through all the other metrics identified and discussed in great detail in the previous chapters."

Comment resolved: IRC 6/14/2012

---

(4) NWD Comment (5/31/12): The Plan included commitments to Habitat Improvement Measures and establishing an adaptive management interagency team (AMT) that are not required or mitigation. The scope of the actions presented are disproportionate to the scope of short and long term impacts, are not within the MCR navigation project authority, and would require additional authority and documentation to complete. The measures also pose a potential fiscal law violation if the expenditures are not attributed to the proper authority. If they were to be included in the project, additionally, their cost would have to be accounted for in the project evaluation.

NWP Response (6/7/12): NWP's reference to habitat improvement measures may have confused NWD. We are not trying to improve the habitat, we are trying to mitigate for impacts from the federal action. One exception to this is the establishment of the snowy plover habitat. The compensation for impacts to wetlands habitat is 2:1, and waters of the US impacts is 1.5:1. The MCACES's cost estimate includes dollars for these impacts. NWP also identified areas in the cost estimate that were mislabeled as mitigation and have been corrected. This district will change the reference of habitat improvement measures (HIM) to compensatory mitigation for impacts to aquatic resources.

Impacts to aquatic resources require mitigation under the Clean Water Act (CWA) as clarified under 33 Code of Federal Regulations (CFR) 332. The district proposes to compensate for the aquatic impacts ranging from 1.5:1 to 2:1 ratio. Since the contractor may or may not use the sites NWP has identified and analyzed in the 2012 Environmental Assessment (EA) and Finding of No Significant Impact (FONSI), an AMT will help the Corps identify what actual in-water impacts need compensation. The AMT will be composed of federal and state agencies which have authority in regards to the mitigation.

Comment resolved: IRC 6/14

---

(5) NWD Comment (5/31/12): Mitigation requirements are for CWA impacted wetlands comprised of 4.7 acres of wetlands and 11.52 acres of other waters of the U.S. The cost of mitigation does not appear to be included in the project alternatives evaluated using the CE/ICA framework and included in the BCR. Also note: Appendix E places mitigation costs at $6,548,886, which seems excessive for small acreage of low quality wetlands.

NWP Response (6/7/12): The cost estimate has been revised to account for only the compensatory mitigation for the major rehab report and not the major maintenance report, with the exception of snowy plover. Because the exact mitigation lands have not been identified yet, a representative site (Lois Island) was used for costing purposes. It should be noted that this is intended to be a maximum cost and therefore cost effectiveness and incremental cost analysis was not performed. The cost estimate is being certified by the NWW cost center of expertise. The district proposes to compensate for the aquatic impacts ranging from 1.5:1 to 2:1 ratio.

For further clarification, the Environmental Assessment (EA) encompasses three separate sets of actions: (1) South Jetty Dune augmentation/stabilization (without project condition: $5.5M in the President's budget for FY 13; (2) North Jetty Major Maintenance Report (MMR): lagoon fill and critical repairs STA 86-99; and (3) the selected plans described in the MRR as basis for an FY 14 budget submittal. The major rehab report is a subset of what is described in the EA.

Comment resolved: IRC 6/14

---

(6) NWD Comment (5/31/12): The certification of the cost estimate is missing. This needs to be submitted with the final report sent for review.

NWP Response (6/7/12): Concur. The cost estimate certification is in process. The signed certification will be provided on 15 June with hard copies of the revised MRR.

Comment resolved: Cost estimate certified by NWW PCX on 13 June 2012

COMMENTS

GENERAL

1. NWD Comment (5/31/12): There were a couple of cases where the "proposed" plan features discussed in the main report did not appear to match the recommended plan. It was difficult to find a good, complete description of what the recommended plan for each jetty included. Recommend review all project descriptions throughout the report and making them concise and consistent.

NWP Response (6/7/12): Concur. NWP will review all project descriptions throughout the report to make them concise and consistent.

NWD Response (6/14/12): Comment resolved.

---

2. NWD Comment (5/31/12): Section 3.5.3.1 – It is not clear which engineering features are in the recommended alternative. Spur groins are stated as being constructed for all the jetties and locations and are shown in Figure 3-26. Table 2-1 indicates that the spur jetties are not in the recommended plan. The basis of this concern is ER 1105-2-100 paragraph E-3. This is a significant concern as it is not clear which features are included in the recommended alternative.

NWP Response (6/7/12): 3.5.3.1 was edited in the following manner.

In areas where foundation scour threatens the overall jetty stability, spur groins were considered in some alternatives. If constructed, the spur groins would be perpendicular to the jetty to facilitate stabilization via accumulation of sediment along the jetty foundation. Historical experience and numerical modeling were used to select the type, depth, and length of spur groin necessary to impact the processes causing increased scour at each jetty (e.g., rip currents, eddies). A range of information was utilized in developing recommended spur groin applications along the MCR jetties. The recommended plan was determined within the framework of trying to specify the lowest impact spur groin layouts (size and number of spurs) suitable to achieving the intended long-term stability purpose of the structures. Information utilized included knowledge of problem erosion areas along the three primary jetties, experience of spur groin application at the South Jetty and Yaquina South Jetty, observation of jetty relic stone wing impacts on shoreward sedimentation, other spur groin studies, and numerical hydrodynamic modeling. The effectiveness of the spur groins is evaluated in the model and compared using average annual costs to decide whether it's more effective to have higher up-front costs by constructing them, or repeated maintenance in those areas to secure the foundation on the jetty trunks without them.

In Sections 4.5 (p. 4-11) and 7.2 (p. 7-2) are explicitly clear that spur groins are not included the recommended plans.

NWD Response (6/14/12): Comment resolved.

---

3. NWD Comment (5/31/12): There is considerable concern about the current relevancy of the ATR which was performed in August – December 2009 and is not only very dated, but more importantly performed on a draft report with a significantly different base condition as well as significantly different recommendations.

NWP Response (6/7/12): The majority of the 2011 draft Major Rehabilitation Report has not changed in the 2012 document under review. The SRB model was modularized and the user's manual revamped; however, the selected plans changed because the base condition changed as a result of a significant IEPR comment. The ATR date referenced in comment is for the technical appendices, not the main report. Attachment 1 is a summary of key events and reviews regarding the MRR, as well as the differences between the 2011 and 2012 reports.

In addition, the ATR lead Robert Patev (CEIWR-RMC-ED) has agreed to conduct such a review in DrChecks along with ATR team members Alan Jeffries, a coastal engineer (CEPOA-EN-CW-HH) and Kevin Knight, an economist (CEIWR-GW). The plan is to ATR the May 2012 report to specifically review the base condition, the evaluation process, and recommendations. Upon resolution of NWD comments, the district will have only the ATR lead, Bob Patev, recheck the final report.

NWD Response (6/14/12): Comment resolved.

---

4. NWD Comment (5/31/12): There is not a consistent applied definition of the base condition throughout the main report. The executive summary (page 2) states the cross section is allowed to deteriorate to 40% prior to repair actions. However on page A2-3-63 defines the base condition allowing deterioration to 35%. The executive summary (page 2) describes that preventive measures will be used in the base condition to avoid a breach of the jetty. However throughout the document (page 3-25, A2-3-60, A2-3-63, A2-3-67, and A2-3-85) breaches are described. The basis of this concern is ER1105-2-100 paragraph E-3. An accurate description and use of the base condition is necessary to evaluate alternatives. Please delete / correct inaccurate descriptions of the base condition.

NWP Response (6/7/12): The correct trigger for above-water cross-section remaining ranges between 30-40% for interim and scheduled repairs. It is not a discreet number because it is represented by a probability density function. NWP is using 35% throughout the report.

NWD Response (6/14/12): Comment resolved.

BACKGROUND & EXISTING CONDITIONS

1. NWD Comment (5/31/12): 2nd to last paragraph p. ii – Here and elsewhere need to provide a figure that illustrates what "..upper portion of the cross section is allowed to be damaged to approximately 40 percent remaining prior to repair actions…" Otherwise this is subject to a lot

of interpretation, upper portion could mean innumerable things from area/volume above the seabed, to area/volume above the MLLW, etc. Damaged could also be interpreted in innumerable ways from missing to fractured, to dislodged, etc…

NWP Response (6/7/12): Concur. Graphics will be added.

NWD Response (6/14/12): Comment resolved.

---

2. NWD Comment (5/31/12): There appear to be inconsistent lengths provided for the South Jetty, e.g. 6.6 miles (Sect 1.2) and 7 miles (4.5 with a 2.5 mile extension) in Section 1.3. This may be due to the extension occurring after some recession occurred and if so that should be clear.

NWP Response (6/7/12): The authorized length of the MCR South Jetty is 6.6 miles. The report will be consistent with that length.

NWD (6/8/12): Comment resolved.

3**.** NWD Comment (5/31/12) Brad: Sect. 1.4, para 4; sect. 1.5.1, 3rd para, p 1-13; sect. 3.2.2, 3.2.5, storm events p. 3-51 and elsewhere. Throughout the document the case is clearly made and documented that degradation of the jetties has accelerated in recent years because of increase storm activity and loss of sand shoal material. Although this point is extremely important to decision making it isn't clear how/if it is incorporated into the SRB model or any attempt to quantify it, perhaps similar to the SLC Figure 3.1. Additionally, sect. 1.4 seems to document this phenomena and sect. 3.2.2 says "…storms may be increasing…". The increased storminess could potentially be a bigger issue than SLC in terms of alternative selection and long term planning. At a minimum, some discussion of the sensitivity of the design and decision making could be done beyond "adaptive management".

NWP Response (6/7/12): This particular issue has been addressed through ATR, IEPR, DQC, and with coastal experts and it was concluded that the model was appropriate. The district has excerpted the comment and response from the IEPR that was finalized in April 2011. Comment response is added here for clarification to see if this addresses and satisfies NWD's comment.

Sea level rise and potential increases in wave height have not been examined sufficiently under different model scenarios.
Basis for Comment:
The issue of climate change, sea level rise, and increased wave action is important to consider in the evaluation of long-term projects (USACE, 2009). There is no discussion in the main report of sea level rise and its impact on this project over the 50+ year project timeline. There is a limited discussion of climate change in Appendix D (p. 5), where the conclusion is that since the projected historical trend of sea level at the project site is estimated to be -0.05 feet in 50 years, sea level rise is not projected to be a significant climate change factor at the project site.

Appendix D states the "comprehensive analysis of historical storm events is expected to adequately capture the present deep water contribution of potential wave height variation for this project site. The above approach forms the basis for estimating the potential changes in wave climate that could affect the MCR jetty system." However, this discussion on wave height trends is not compelling. The main report states (p. 1-6), "As the tidal shoals continue to recede (erode), the MCR jetties will be exposed to larger waves and more vigorous currents. To make matters worse, the regional wave climate along the Northwest Pacific Coast has become more severe in the last 10 years. The offshore 100-year wave height has been revised from 41 to 55 feet." (see also Appendix D). The main report states (p. 3-42), "The limit of cross-section resiliency is reached for jetties when the core stone becomes exposed to wave attack." Therefore, this issue may affect jetty erosion and a larger range of wave heights should be included in both the SRB and STWAVE model scenarios. Wave overtopping is central to the environment deteriorating the existing jetties. As the planning horizon of this project is 50+ years, it seems that a discussion would be useful of sea level rise and modeling potential wave heights and the wave overtopping impacts on the jetties given different rates of recession under a wider range of wave heights. Jetty height and crest elevation are variables that should be modeled given the potential larger wave heights possible under sea level rise. Although the selection of the recommended plan may not change, long-term maintenance costs may be affected, therefore consideration is warranted. Appendix B states that transient internal hydraulic effects of wave impact may be the most important parameter in the stability of the jetties. However, it is the least certain of all of the parameters. Internal hydraulic pressures in jetties have not been measured. Given this, it seems especially important to consider more extreme wave heights beyond the wave height analyzed, with respect to sea level rise and potential increasing wave height.
Significance – Medium:
The discussion of potential impacts of sea level rise and increased wave action on jetty structures is critical to understanding the potential impacts to the project and in designing a project with lower long-term maintenance costs.

Recommendations for Resolution:

1. Add a separate section to the Major Rehabilitation Evaluation Report that examines climate change, sea level rise, potential wave height changes, and resulting wave overtopping impacts on the jetties given different rates of recession under different model scenarios.

USACE Draft Evaluator Response (#11)

Final Panel Comment #11 NON-CONCUR

Discussion of potential sea level rise as well as its impact on potential future loading on the MCR jetties has been included in Appendices A1 and A2. Portions of that discussion can be moved to the Main Report for completeness.

All of the factors discussed above have been incorporated into the wave height loading for the structures. An extremal analysis has been performed utilizing the period of record for the Columbia River NDBC buoy producing the expected long-term estimates of extremes at the project area. This estimate compares well with the recent analysis conducted by Ruggiero for the Oregon coast wave climate. An incremental increase in wave height has also been included to reflect the potential for an upward trend in storm intensity. The project event tree simulation includes a function that gradually increases the depth-limited wave height incident to the structure as the scour increases and the water depth at the structure increases.

The potential for sea level rise was incorporated in the project event tree simulation and life cycle analysis of the project. As directed by USACE (2009), three separate potential sea level curves were estimated placing the potential sea level change at the project site over the 50 year planning horizon somewhere between -0.05 ft to +1.6 ft. Each life cycle run for the project utilized one of the sea level change curves in order to factor in that potential change in project loading and its impact on maintenance requirements and effectiveness. With the slightly greater water level at the project site during these realizations, the incident wave height was also adjusted accordingly. So the future case scenarios incorporate both a higher water level as well as the impact of wave height.

1. **ADOPT NOW** by moving the sea level rise section of the report to the Main report for better clarity. In the analysis, the waves are currently estimated at three different potential water levels. The relative mildness of sea level change at the project site makes the inclusion of sea level change in the total loading environment less of a driving factor in a long-term maintenance strategy. In addition, due to the uncertainty of future sea level rise scenarios, the most likely approach for very large rubblemound structures for future maintenance would be to develop an adaptable maintenance strategy that could be modified as the gradual change is observed.

NWD Response (6/14/12): Comment resolved.

4. NWD Comment (5/31/12): Section 1.5.1, sect. 1.5.1.3, 1.5.1.4, 1.5.2 and elsewhere, the point is clearly demonstrated here and throughout that the loss of sand shoal material is a major contributor to the failing condition of the jetties. What isn't discussed is whether the significant reduction in sediment load in the Columbia system since the construction of the dams is potentially a contributing factor (loss of source material). The increase in active storage from 213KAF to 49MAF from 1910 to 1968 has had a tremendous impact on the hydrograph for the basin and correspondingly ability to transport sediment. How are we applying a watershed approach to the evaluation?

NWP Response (6/7/12): We are not applying a watershed approach to major rehab. It is outside the scope of a major rehab. That would need to be evaluated under general investigation study. The foundation concerns were addressed through IEPR. Additionally, the Corps and the region are investigating ways to place dredged material from the mouth of the Columbia River in near-shore areas north and south of both jetties respectively. This will also aid in reduction of the shoaling concern.

NWD Response (6/14/12): If the significant change in quantity of sediment supplied to the MCR doesn't affect the stability or plan evaluation to the jetties, then the report should so state. Not addressing this because this isn't a GI study isn't an adequate response.

Report modified to indicate change in sediment quantities not evaluated in report.

NWD Response (6/14/12): Comment resolved.

---

5. NWD Comment (5/31/12): P 1-19. Here and elsewhere the concrete terminal of the south jetty is discussed. What impresses is that this south jetty head has remained functional and above water for over 70 years in this extremely violent environment. Referencing pg A2-3-66, assuming it will be above water for another 12-20 years will make it 90 year life. Recommend discussing if this was considered and if so, why eliminated as it seems to have performed incredibly well. Also, relate to assessment in 3.5.2.1.

NWP Response (6/7/12): The referenced paragraph states, "the entire cap has been severely damaged due to the severe wave climate – and is progressively failing." The cap is predicted to be non-existent within 12-20 years.

NWD Response (6/14/12): The point is that a 90-year life is really good survival in this violent environment. The question is "why wouldn't we 'consider' using a technique that has a demonstrated longevity of 70-years and a likely life of 90-years?"

IRC 6/14/12 comment closed: Agreed that all head stabilization options will be reviewed in DDR

---

6. NWD Comment (5/31/12): Sect. 1.5.4.1 and elsewhere. There is an assumed near linear progression in the recession rates of the jetties. Is this realistic as the recession continues into progressively shallower water? Would this affect the alternative evaluation?

NWP Response (6/7/12): The overall assumption is that the North Jetty and Jetty A would be built back to a station certain and not allowed to recede back into shallow water. The South Jetty is not built back to a station certain in the selected plan, but the head will be stabilized when construction efforts are occurring at the end of the jetty. The predicted linear recession of the jetty was used for illustrative purposes. In Figures 1-24, -26 and -31, the linear portion was just used for simplicity. It represents two possibilities of recession as a constant if no action is taken. It is not meant to infer it is a linear regression.

NWD Response (6/14/12): If the linear progression was NOT used in the alternative analysis, so state.

NWP Response (6/14/12): Recession of jetty heads used in alternatives are based on the wave climate and structure response for the alternative being modeled.. Hold Head alternatives continue to re-construct to existing end-points. Those endpoints are: NJ-101+00, JA-89+00, SJ-head recession is assumed to reach 290+00 by 2020 for selected plan,

Comment Closed: IRC 6/14/12

---

7. NWD Comment (5/31/12): Top of page 1-48 and throughout. The report repeatedly makes the point about the function, importance and performance of groins, but dismisses in the final evaluation without much discussion on why groins are no longer are that important/functional. Seems very inconsistent in terms of value of these engineering features.

NWP Response (6/7/12): Concur. The Corps began looking at applying a system approach to the MCR entrance in 1999. The following will be incorporated into Chapter 4 and the Executive Summary.

The Corps began looking at applying a system approach to the MCR entrance in 1999. Throughout FY 06-10, NWP considered where the end of each of three jetties should be at the mouth of the Columbia River and developed three jetty length options:

- rebuild the jetties to their authorized lengths
- rebuild the jetties to the midpoint between the authorized length and the existing jetty end station
- rehabilitating the jetty to the current end station

NWP has considered major alternatives to the authorized cross-section that included designs that stayed on the existing footprint and those that went off the existing footprint, including realigning the entire system.

Alternatives that extended the jetty lengths significantly beyond the existing end station or reconstructed the jetties off the existing footprint were deemed infeasible.

In FY 2010, a 90% draft of the MRR underwent District Quality Control (DQC) and Agency Technical Review (ATR). The underlying tenets of that report included a base condition involving a fix-as-fails approach where each jetty was allowed to degrade as low as 20% of the originally authorized cross-section remaining above MLLW -5, resulting in forecasted breaches. The hypothetical breaches would release material into the navigation channel, leading to emergency dredging. Breaches were forecasted to primarily occur in the winter, thus emergency dredging was very expensive, and reliability of the navigational channel became questionable. Moreover, breach volumes entering the navigation channel were difficult to quantify. In an attempt to model these effects, the SRB model code became more complex as the analysis was developed and the timing of the runs became very long and the economics was embedded within the model code. NWP also developed a qualitative numeric scoring of alternatives that included several factors beyond average annual cost.

The IEPR was conducted from December 2010 through April 2011. Concurrently, the SRB model underwent substantial review, including ATR approval and DDN-PCX model certification in January 2011. This documentation was then forwarded to HQUSACE for final approval where it was disapproved in June 2011 because the IEPR panel raised concerns about the frequency and severity of breaching and sediment transport in the base condition.

After consultation with NWD, it was decided that an MMR should be produced for the most critical portions of the North Jetty for inclusion in the FY 2014 budget submission. Therefore, the lagoon fill between STA 20 to 60 and critical repairs between STA 86 to 99 were removed from the MRR alternatives and included in the revised base condition.

NWP then decided to revise the SRB model, MRR and appendices per IEPR comments and hired Moffatt & Nichol, a coastal engineering consultant. Furthermore, the A/E task order emphasized improving the model code; showing compliance with current technology and Corps policy; providing additional documentation; improving practicality with data inputs and outputs; and user manual; clearly identifying the use and limitations of the model consistent with EC 1105-2-412.

Due to the level of construction and high mobilization costs, the revised FY 12 base condition—identified as an interim-repair approach—was developed to replace the FY 11 “fix-as-fails” approach. The new base condition allows the upper portion of the jetty is allowed to be degraded until approximately 40% of the cross-section is remaining prior to repair action being initiated. This change in the base condition allows for repair actions to take place prior to a breach event, and thereby eliminates breaching and sediment transport through the jetty, affecting the navigational channel and significantly reduces winter emergency dredging.

The economics analysis is now outside the model in a post-process spreadsheet. The code has been modularized and simplified so that there is one code for all three jetties. The user’s manual provides enough detail for a knowledgeable coastal engineer to run the model. These changes improved the transparency of the model's sub-routines, dependant and independent variables, and damage functions leading to the ultimate approval of the model on 27 April 2012.

The above series of events resulted in a change in the selected plans for the three jetties.

ER 1105-2-100, Appendix G (pp. 7-8), states: "Identification of the NED plan is to be based on consideration of the most effective plans for providing different levels of output or service. Where two cost-effective plans produce no significantly different levels of net benefits, the less costly plan is to be the NED plan, even though the level of outputs may be less."

It is important to note that the purpose of the authorized project is to maintain a reliable, functioning, deep-draft navigation channel through the Columbia River entrance. It is not to compare the structural components of each of the alternatives so that if two alternatives still result in no impact to the navigation channel, their benefit is treated as the same. Therefore, the alternatives were evaluated based on least cost as long as they still provided for a usable channel.

In addition, the price of jetty stone and the quantity needed to construct the spur groins proposed outweighed the predicted benefit of repeated maintenance. This assumption will be monitored in the recommended plan throughout time and if foundation conditions deteriorate, threatening or affecting the jetty's stability, this decision will be revisited in the future.

NWD Response (6/14/12): Comment resolved.

---

8. NWD Comment (5/31/12): Sect 1.6 is kind of vague and really doesn't say much to convey the significance of the jetties. Suggest adding something to the effect of "While we do not have the methodology (technology/capability) to quantify impacts of continuing deterioration to deep draft navigation we can be sure that continued deterioration will result in reduced ability to maintain channel depths required for current traffic. If the channel becomes unstable or reverts back to a reduced depth the significant benefits of the Columbia/Snake River system will be at risk".

NWP Response (6/7/12): Concur. The following text will be added to Section 1.6: "While we do not have the methodology (technology/capability) to quantify impacts of continuing deterioration to deep-draft navigation, we can be sure that continued deterioration will result in reduced ability to maintain channel depths required for current traffic. If the channel becomes unstable or reverts back to a reduced depth, the significant benefits of the Columbia/Snake River system will be at risk."

NWD Response (6/8/12): Comment resolved.

---

9. NWD Comment (5/31/12): Sect. 2.2. Here and elsewhere, a case is never made under what conditions jetty deterioration would result in failure to maintain navigation. This would seem critical to the evaluation.

NWP Response (6/7/12): Concur. The base condition will be rewritten to clearly explain the assumption that closure of the MCR will not be allowed to occur. The following language will be added to Sec. 2.3 and wherever necessary to make it clear that MRR base condition prevents a breach and therefore a potential failure to maintain the navigation channel. As stated in Section 4.2: "The base condition for this study is identified as an interim repair approach because the upper portion of the cross-section is allowed to be damaged to approximately ranges from 30-40 percent remaining prior to repair actions being taken. In this way, the jetty is maintained close to the margin of functional loss without breaching."

NWD Response (6/14/12): Comment resolved.

---

10. NWD Comment (5/31/12): Unlabeled figure, top of p 2-3. There appears to be a notable drop in traffic at the MCR in 2009. This begs the question – why? Did this continue in 2010 and 2011? Was it an aberration? Also, the Columbia River Channel Improvement project is not discussed. The case was made that it is necessary to maintain commerce on the Columbia River. It would seem relevant to mention here.

NWP Response (6/7/12): NWP will add figure title on page 2-3. In 2007, the estimated annual value of shipping $17B; in 2010 it was $20B. There are many reasons that the total volume of traffic on a year-to-year basis through the Columbia River would be impacted; global trade, different users of the river, shifts in traffic between the Puget Sound and the Columbia River, and the needs of local industry. Although the traffic diminished in 2009 at $17 billion and 36 million short tons, there is still ample demonstrated need for navigation on the Columbia River. Additionally, since the completion of construction of the Columbia River Deepening Project in 2010, more than $200 million in infrastructure has been built in the Lower Columbia River to support growing needs for deep-draft navigation in the system.

NWD Response (6/14/12): Comment resolved.

---

11. NWD Comment (5/31/12): Sect. 2.5. This is a very interesting fact that navigation has only been disrupted once, in 1929. Although it isn't clear exactly what that means. Have there not been any inbound or especially outbound delays during the history of the jetty system? It would seem that with the jetty system at its most deteriorated (minimal) condition since about 1913, with deeper draft vessels now plying the entrance and an environment of greater storms and wave heights, we might start expecting delays without repair. Was this assessed?

NWP Response (6/7/12): The following text has been added to Sec. 2.5: Transportation and delay benefits were not assessed because the assumption was the mouth of the Columbia River would remain open; would be maintained to the best of the Corps' ability based on available funding. To quantify transportation and delays is difficult in any entrance and specifically at the mouth of the Columbia River. There are closures at the MCR that are the decision of the US Coast Guard due to storm and wave conditions at the entrance. The offshore wave climate and the effects on the inlet and separating those effects to be dependent upon the jetty would be difficult; therefore the assumption was made that the Columbia River would remain open.

NWD Response (6/14/12): The difficulty of the assessment is understood, but the critical question is whether it may have an impact or not. Is it fair to say the contribution to delays from the jetty condition above and beyond the base condition is not a significant contributor to delays?

NWP The Base condition states that the jetties will be maintained at a minimum level that prevents consequences to the navigability of the inlet. The statement "Is it fair to say the contribution to delays from the jetty condition above and beyond the base condition is not a significant contributor to delays?" is correct

NWD Response (6/14/12): Comment resolved.

---

12. NWD Comment (5/31/12): Last paragraph sect. 2.5. "costs avoided" is not very descriptive. What does this include? Dredging? Maintenance? Rescues? Other?

NWP Response (6/7/12): Reference chart C-17. See Chapter 4 rewrite.

NWD Response (6/14/12): Comment resolved.

---

13. NWD Comment (5/31/12): Is tectonic rebound accounted for (or significant) in this evaluation?

NWP Response (6/7/12): It is accounted for in the sea-level rise evaluation and is not considered to be significant.

NWD Response (6/14/12): Comment resolved.

---

14. NWD Comment (5/31/12): Page 3-22, second paragraph discusses proposed spur groins. Are they in the recommended plan (part of scheduled repair)? It does not look like it but the descriptions in Sect 4.5 are pretty brief. Jumping back to 4.4.1 it looks like groins would be in "scheduled repair with engineering features" and the recommended plan is apparently "without engineering features" but it's not entirely clear.

NWP Response (6/7/12): Chapter 3 of the MRR discusses engineering considerations and is meant to fully describe the engineering approach and terminology, the base condition and alternatives. Chapter 4 will assess those alternatives and fully describe the selected plan. The following text will be added to 3-22 and potentially to 3.5.3.1.

In areas where foundation scour threatens the overall jetty stability, spur groins were considered in some alternatives. If constructed, the spur groins would be perpendicular to the jetty to facilitate stabilization via accumulation of sediment along the jetty foundation. Historical experience and numerical modeling were used to select the type, depth, and length of spur groin necessary to impact the processes causing increased scour at each jetty (e.g., rip currents, eddies). A range of information was utilized in developing recommended spur groin applications along the MCR jetties. The recommended plan was determined within the framework of trying to specify the lowest impact spur groin layouts (size and number of spurs) suitable to achieving the intended long-term stability purpose of the structures. Information utilized included knowledge of problem erosion areas along the three primary jetties, experience of spur groin application at the South Jetty and Yaquina South Jetty, observation of jetty relic stone wing impacts on shoreward sedimentation, other spur groin studies, and numerical hydrodynamic modeling. The effectiveness of the spur groins is evaluated in the model and compared using average annual costs to decide whether it's more effective to have higher up-front costs by constructing them, or repeated maintenance in those areas to secure the foundation on the jetty trunks without them.

NWD Response (6/7/2012): Chapter 3 information is resolved. NWD will be reviewing Chapter 4 rewrite.

NWD Response (6/14/12): Comment resolved.

---

15. NWD Comment (5/31/12) **Brad**: Pg. 3-22, 3rd para. Similar except for jetty head feature. The discussion proposed ne w jetty head features 100 feet offshore form present above water terminus for north and south jetties and 400 feet for jetty A. This does not seem consistent with recommended plan for the jetties, especially the south jetty. The proposed plan needs to be consistent with the recommended. Perhaps it's a case of discussing one proposed option (ideal?) considered rather than the recommended plan but it should be made clear if that is the case. Also, Para 3.4.1 in particular makes a point how critical stabilization of the jetty head is, yet is dismissed in final alternative selection.

NWP Response (6/7/12): 3rd paragraph on pg. 3-22 is meant to discuss generically what jetty head capping would entail. It is not intended to represent the recommended plan. The last paragraph will be edited to say "would be" constructed instead of "will be". EDIT MADE.

NWD Response (6/14/12): Comment resolved.

---

16. NWD Comment (5/31/12): Pg. 3-25. States jetty segment loses function when has been reduced to less than 15%+- 5% of original standard upper cross-section. Collaborate this with the 40% mention in the introduction and provide figure demonstrating what this means precisely, particularly as it relates to the "upper cross-section" piece.

NWP Response (6/7/12): The description given on page 3-25 of 15% upper cross-section remaining defines a breach condition. The 30-40% range defines the remaining cross-section of the damaged reach that triggers a repair action. These two ranges describe the remaining cross-section above -5 MLLW, except where -5 MLLW occurs below ground. The elevation is brought progressively up to remain just above ground in areas of the jetty root.

NWD Response (6/14/12): It would be helpful to show label both of these conditions on the figure being added to show the 40% (from a previous comment).

NWP Response (6/14/12): Concur. Labels added to graphs.

NWD Response (6/15/12): Comment resolved.

---

17. NWD Comment (5/31/12): P. 3-28. 1st paragraph. Again, no mention of potential delays to navigation. State whether this is a concern.

NWP Response (6/7/12): The 1st paragraph will be modified in the following way: "A jetty breach at the MCR, if it occurred, would allow flow through the jetty and destabilize adjacent morphology. Elevated shoaling at the MCR would occur. Aggressive dredging may be required to maintain the MCR navigation channel and the jetty may require emergency repair. The distinction should be made between jetty damage and jetty failure and MCR project function failure. The primary function of the MCR project is to maintain the navigation channel for deep-draft shipping. The secondary function evaluated in the structure rehabilitation effort is to significantly extend the life and reliability of the jetties in order to reliably maintain the primary function. Subcategories addressed in order to accomplish the primary purpose included: prevention of a significant breach to the jetties, minimizing dredging of the channel, minimizing the frequency and magnitude of the required jetty repairs, and reducing the degradation rate of the jetties over time."

The 2nd paragraph will be modified in the following way: "If a jetty breach were to occur, it would likely occur during winter (October through March) in response to storm waves. Due to the typically severe weather conditions at the MCR during winter months, emergency jetty repairs (to fill the breach) and/or emergency dredging activities (to maintain the navigation channel) may not be possible or may only be possible at a reduced rate, with the end result likely being impacts to navigation until the actions can be completed. Jetty repairs are expensive and due to the sheer size of the structures usually include high costs of mobilization. Because these jetties are typically repaired from the top of the structure (especially during winter months), construction of a haul road is required for each jetty repair effort. In addition, there are some areas along the seaward half of the North and South jetties for which emergency jetty repairs during the winter months could not be conducted, due to the exposure of the construction site to overtopping wave conditions. Impacts to navigation would occur." EDITS MADE.

NWD Response (6/14/12): Comment resolved.

---

18. NWD Comment (5/31/12): Page A2-3-77, Section 3.10, first paragraph discusses the potential for emergency dredging saying the contract dredges are typically working in warmer climates. The report should add that the contract dredges are typically working at projects on the east and gulf coast where work is limited to an environmental window and not expected to be

available to mobilize to the west coast. The dredge ESSAYONS is also generally in repair status and not likely to e available during the winter months.

In short, dredges are typically not available for dredging at the mouth during the winter months when a breach and sudden infill are likely to occur and the risks of dredging at the MCR during that period are very high so channel depths will likely be lost for an extended period. We typically have two dredges working at MCR for a total of 80-100 days per year to dredge 4-5MCY during favorable weather each year. The ability to dredge an additional 2-3MCY, (during the winter) is highly unlikely. Similar language should be added to Sect. 3.8.3.1 on page A2-3-65 where the report discusses some of the challenges with emergency dredging.

NWP Response (6/7/12): The 1st paragraph of section 3.10 will be edited to read: "The purpose of this rehabilitation study was to identify and recommend a course of action that would minimize future life-cycle costs and maintain deep-draft navigation for the MCR jetty system. While this was a least cost analysis, various additional elements including project reliability, constructability and access, and potential navigation risk were also considered in the alternative comparisons and rankings. The complexities of major jetty repair in challenging conditions, as well as the feasibility of emergency winter dredging at the MCR, were considered in the final evaluation. Only four contract dredges are capable of dredging at the MCR during winter conditions, and they are normally scheduled for work in milder climates during the winter months. Contract dredges are typically working at projects on the east and gulf coast where work is limited to an environmental window and not expected to be available to mobilize to the west coast. The Corps' dredge ESSAYONS is also generally in repair status and not likely to be available during the winter months.

In short, dredges are typically not available for dredging at the MCR during the winter months when a breach and sudden infill are likely to occur and the risks of dredging at the MCR during that period are very high, so channel depths will likely be lost for an extended period. We typically have two dredges working at MCR for a total of 80-100 days per year to dredge 4-5 MCY during favorable weather each year. The ability to dredge an additional 2-3 MCY (during the winter) is highly unlikely. The best-performing alternative for each jetty was selected by optimizing the initial cost of structure rehabilitation, optimizing future maintenance costs, and considering the time-varying reliability of the jetty."

NWD Response (6/8/2012): Comment resolved.

ALTERNATIVES ASSESSMENT

1. NWD Comment (5/31/12): There appears to be a considerable disconnect in the assessment of alternatives in terms of perceived accuracy of average annual costs (AAC) and the true accuracy of these numbers. In the selection of the NED plan the AAC numbers presented are treated as if they are discrete numbers, when in fact the considerable uncertainty in these numbers makes several alternatives (5 to 6 for both North and South jetty alternatives) virtually identical in terms of cost.   Any accuracy implied beyond two significant figures is completely unreasonable for values with this much uncertainty, anything beyond 5% accuracy is not likely to be supportable

either. More detailed analysis of the estimates was performed by Moffat and Nichol for north and south jetties – coasts are “very small and indistinguishable”. This is not true for Jetty A, where there is a much clearer NED plan – the recommended plan.

<u>NWP Response (6/7/12)</u>: ER 1105-2-100, Appendix G (pp. 7-8), states: “Identification of the NED plan is to be based on consideration of the most effective plans for providing different levels of output or service. Where two cost-effective plans produce no significantly different levels of net benefits, the less costly plan is to be the NED plan, even though the level of outputs may be less.”

<u>NWD Response (6/14/12)</u>: This comment is significantly addressed with major additions to chapter 4. The piece still under further review is the implied accuracy of the cost estimate - showing to 4 figures of accuracy when a case can easily be made that they could be shown to just two. One alternative at $10 million AAC and another at $10 million with the same benefits are both the NED plan. Chapter 4 writeup in particular for north and south jetty (telling the story) may make the case that base condition is the preferred alternative.

<u>NWP response (6/15/12)</u>: District decision to support selected plan in report.

<u>NWD Response (6/14/12)</u>: Comment resolved.

---

2. <u>NWD Comment (5/31/12)</u>: It is stated in the executive summary and in the assessment of alternatives that alternatives are being assessed against several metrics (4, 5 or 6 depending on where you read), but determination of the recommended plan is based only on one of the listed metrics, the AAC. It is unclear if or how structural and functional reliability or constructability is included in these assessments.

<u>NWP Response (6/7/12)</u>: Our stochastic risk-based model (SRB) evaluates structural and functional reliability as related to damage and repair strategies and rehab alternatives. The output is converted to average annual cost outside the model as a simplistic way of combining all of these different factors into one type of metric. All of the evaluated plans are found to be acceptable when considered against the bulleted list in the executive summary.

Section 4-3 will be edited in the following way:

“The purpose of this rehabilitation study was to identify and recommend a course of action which minimizes the future life-cycle costs and maintain deep-draft navigation for the MCR jetty system. The starting point for this evaluation was to formulate alternatives that met the project purpose, and met acceptable levels of project reliability, constructability, and potential navigation risk. Alternatives varied by jetty geometry, including crest-width and -height, side slope, benching, and whether or not they included engineering features (spur groins and capping). The alternatives were further distinguished by holding the head location throughreconstruction of cross-section, or through capping. These alternatives were evaluated using the SRB model providing required repair volumes through time and by reach. The required repair volumes were converted to life-cycle cost and ultimately to an average annual cost for each alternative. The life-cycle costs included initial construction cost, repair cost, and their timing after rehab. The average annual cost of each alternative was put in ranked order and the recommended plan was chosen based on least-cost.

Alternatives including rebuilding submerged sections of each jetty were screened out in the early phases of the study. These alternatives included rebuilding up to the full authorized length, constructing jetty heads on currently submerged relic stone, rebuilding the cross-section off of the existing footprint, and realigning the jetties. Hence, these alternatives were unacceptable and eliminated from further consideration because they were either outside of the authorized project, or deemed unacceptable from a constructability standpoint. The current length of each jetty is generally deemed to result in an acceptable level of navigation access and maintenance dredging, meaning that rebuilding submerged sections of the jetty would have limited potential benefit. Although it was conclusively demonstrated that use of extremely large, dense stone in larger cross sections will reduce future maintenance costs, none of the rehabilitation alternatives proved to be cost effective.

The recommended plan will identify the optimum investment both in terms of proposed actions and timing of proposed actions, given the risk and uncertainty identified during the study. This plan will offer the greatest benefit to the project with respect to cost while still meeting the project goals."

NWD Response (6/14/2012): Further discussion is needed on this topic. This statement makes it sound like reliability IS included in the AAC. In appendix A, specifically page A2-4 and A2-7 it states "reliability is not used to simulate structure response and related consequences (life-cycle cost)." It is included in the AAC or it is not, please explain which.

Much improved language. However, this sounds like reliability was used as a screening criteria and not included in life-cycle cost.

NWP response (6/14/12) IRC: Reliability and damage simulated by the model share some parameters, slope, rock size etc, therefore both reliability and damage cannot be combined into the AAC or these parameters would be "double-counted". The alternatives brought forward are analyzed for functional reliability as a check to ensure that selected plan will perform.

NWD Response (6/14/12): Comment resolved.

---

3. NWD Comment (5/31/12): There is only one number reported in the Plan Selection Tables (tables 4-1 through 4-3). That is average annual cost (AAC) . This is informative, but variance in the makeup of this single number would be extremely informative for comparison between alternatives. For instance a listing of the breakdown by the six categories making up this number: 1) repair activities; 2) rehabilitation activities; 3) additional fixed cost of activities; 4) Jetty head capping; 5) spur construction; and 6) normal dredging; would all be equally telling and informative on tradeoffs between alternatives.

NWP Response (6/7/12): Concur. We will insert table C-17 into Section 2.7.

NWD Response (6/14/12): Comment resolved.

---

4. NWD Comment (5/31/12): In the executive summary and elsewhere the important point is made that there is $20 Billion in international trade annually passing through the protected area of the MCR jetties. Further, the report states that the project was authorized "to secure consistent navigation through the coastal inlet". However, in the alternative evaluation it isn't assessed how the various alternatives perform in relation to the authorized purpose nor if the project or lack thereof would impact the $20 billion in trade.

NWP Response (6/7/12): In our alternative formulation description, all plans met the authorized purpose. Text has been revised in both the executive and summary and chapter 4 to clarify that all evaluated plans met the authorized purpose.

NWD Response (6/14/2012): Comment resolved.

---

5. NWD Comment (5/31/12) Pg. 3-37. Assessment is limited to 2:1 and 3:1 slopes, but all recommendations are steeper. What is the assessment of the steeper slopes.

NWP Response (6/7/12): Reference section is to the physical model and not alternatives being evaluated. The physical model used 2h:1v and 3h:1v slopes, but the alternatives analyzed by the SRB model used various sized slope ranging from 1.25h:1v to 3h:1v. The steeper slopes represent the historical repair design parameters and the current cross-section of each jetty. The flatter slopes were modeled in the physical wave tank to see if they would perform better than the existing design (see Tables 1-2, 3 & 4).

NWD Response (6/14/2012): As mentioned earlier, table c-17 is significantly better, however table as provided in draft of chapter 4 is even better yet.

NWD Response (6/14/12): Comment resolved.

---

6. NWD Comment (5/31/12): Page 3-47, Sect, 3.5.3.2, paragraph 3 says the rebuild of the south jetty head was not considered a viable rehab option. Is that referring to technical viability (I read it that way) or the fact that it was not found economically justified? These are two different determinations and the meaning should be clear. The paragraph goes on to say it was proposed to be stabilized at approximately its current location, but that is not the recommended plan. Dropping consideration of rebuilding of the south jetty head is a major consideration; discuss briefly why it is not viable.

NWP Response (6/7/12): Holding the head at station 313 proved to be less cost-effective than continuing to allow the jetty to recede, per the model, with available information. All alternatives that involved rebuilding the south jetty head utilized existing relic stone as a foundation. Constructing the jetty head offshore from the current position of the end of the jetty to its authorized length was deemed infeasible due to the extensive scour hole and depth of water at the authorized south jetty terminus location.

Section 3.5.3.2 paragraph 3 will be revised to say:

"Based on the several constraints (see discussion in Section 11 of Appendix A1), the rebuild of the South Jetty head (presently located 1,500 feet inshore of the concrete monolith) was not considered a viable rehab option. Constructing the jetty head offshore from the current position of the end of the jetty to its authorized length was deemed infeasible due to the extensive scour hole and depth of water at the authorized south jetty terminus location. The head of the South Jetty was considered to be stabilized at approximately its current location (stations 313-315). Maximum viable rebuild of the North Jetty head was determined to be station 105, which would result in a re-established head position 1,700 feet inshore of the fully authorized length. Maximum viable re-extension of the head for Jetty A was determined to be station 93, which is 500 feet seaward of its current position and 400 feet landward of its full authorized length. Jetty A length is important to controlling erosion along the North Jetty foundation; however, the substantial scour hole south of the Jetty A head limits a cost-effective head rebuild." EDITS MADE.

NWD Response (6/14/12): Comment resolved.

---

7. NWD Comment (5/31/12): 3.6.4 -- Here or somewhere it would be helpful to discuss very briefly the survey techniques used over the years to provide this good historical record. It could be meaningful if there was some opportunity for a systemic error sometime over the years.

NWP Response (6/7/12): This text was added to 3.3.2: Survey methods range from aerial LIDAR combined with bathymetric surveys to annual, on-the-ground surveys using GPS and hip-chain to locate station. The 2010 on-the-ground survey is included as Appendix A-4 in the report. Future surveys will use LIDAR/bathymetric methods and be compared biannually to track damage and jetty stone loss.

NWD Response (6/14/2012): Comment resolved.

---

8. NWD Comment (5/31/12): Sect 3.10. This is an extremely meaningful evaluation yet seems to be widely ignored in the alternative plan selection. For instance it is pretty clear that the best alternatives are: North Jetty, Scheduled repairs w/Features and Scheduled repair w/Features (hold head); South Jetty, Scheduled repair w/head capping, scheduled repair w/features, scheduled repair (hold head) and scheduled repair w/features (hold head) are virtually the same and clearly the best; Jetty A, Small Template – Plan A, Small Template – Plan B, Small Template –plan A (hold Head), Small template – plan B (hold head) are virtually the same and clearly the best.

NWP Response (6/7/12): Please refer to previous responses regarding NED and least-cost plan.

NWD Response (6/14/2012): Changes to chapter 4 may resolve this comment.

NWP Response (6/14/12) IRC: District supports plan selected

NWD Response (6/14/12): Comment resolved.

---

9. NWD Comment (5/31/12): Sect. 4.3 This is perhaps the most important section in the report, yet seems to be inconsistent with the story that is being told prior in the report. The metrics purported to be used don't seem to be used other than AAC in alternative screening. Additionally, paragraph states 5 metrics, but only lists 4. Is one missing? This is also inconsistent with the metrics mentioned in the executive summary which includes 6 metrics. Also states that none of the other metrics translated into the AAC. Paragraph is confusing and inconsistent with the report elsewhere. Are there several metrics or is AAC the only metric?

NWP Response (6/7/12): See NWP response for BLUF #2.

NWD Response (6/14/2012): Comment resolved.

---

10. NWD Comment (5/31/12): A general documentation for computation of AAC should be included in the main report? It is very challenging to see by referencing between the engineering appendix and the economics appendix how these numbers were developed? This is absolutely critical and only provided cryptically. The story is not clearly told.

NWP Response (6/7/12): Table C-17 will be added into section 2.7.

NWD Response (6/14/2012): Updated chapter 4 largely answers this question. Still need to close out the issue on least cost. Although the updated chapter four is now reporting the AAC in thousands rather than down to the dollar, the report has still made a choice by cutting the line so thinly. It is completely reasonable to report these numbers in millions - for instance, the top three could be reported as $9.6 million AAC. Clearly the accuracy of these numbers over 50 years with all the uncertainties involved cannot be computed more precisely than this.

NWD Response, IRC (6/14/12): Comment resolved.

---

11. NWD Comment (5/31/12): 4.4.1 North Jetty plan selection: Recommends Scheduled repair, holding the end station. This recommendation seems to be solely based on just one of the five (4 or 6?) metrics – AAC. It is noted that 5 of the other alternatives for the North Jetty are within 5% of the AAC for this option and 3 are within 3%. With the tremendous uncertainty in the future performance of the structure, large contingencies on cost estimates and other factors, these are all virtually the same costs and not sufficient variance to make a decision on. Ironically, the selected alternative, isn't even one of the clear best alternatives in terms of reliability. The

evidence in the report would suggest that either schedule repair w/features (BCR 1.06) or schedule repair w/features (hold head) would both be better alternatives (1.04).

NWP Response (6/7/12): See response for General Comment #2 and Alternative Assessment Comment #2.

NWD Response (6/14/2012): Updated chapter 4 largely answers this question.

NWD Response (6/14/12): Comment resolved.

---

12. NWD Comment (5/31/12): 4.4.2 South Jetty. Although, accurately portrayed as none of the alternatives having a BCR greater than unity, five were virtually at unity and all gave much greater reliability than the selected alternative. One alternative was within 8/1000's of a percent, yet was dismissed as not being the NED. Ironically, although costing virtually the same, the selected alternative clearly has the lowest reliability. It would appear that three other alternatives would be better choices than the selected plan – scheduled repair (hold head) and scheduled repair w/head capping and spur groins (hold head) and scheduled repair w/spur groins only.

NWP Response (6/7/12): After initial screening, all alternatives brought forward into Chapter 4 were acceptable and least cost plan was selected.

NWD Response (6/14/2012): Updated chapter 4 largely answers this question. Still need to close out the issue on least cost. Although the updated chapter four is now reporting the AAC in thousands rather than down to the dollar, the report has still made a choice by cutting the line so thinly. It is completely reasonable to report these numbers in millions - for instance, the top three could be reported as $9.6 million AAC. Clearly the accuracy of these numbers over 50 years with all the uncertainties involved cannot be computed more precisely than this.

NWP Response (6/14/12) IRC: District supports plan selected

NWD Response (6/14/12): Comment resolved.

NAVIGATION BUDGETING

1. NWD Comment (5/31/12): The report needs to state very strongly in the Executive Summary and the conclusion that the BCR numbers for each of the jetty repair alternatives do not reflect or capture the benefits of the MCR system. The BCR numbers are at or near 1 and under the current budget climate are not likely to be supported for funding but they do not tell the full story of the importance of maintaining the jetties to provide a reliable navigation system on the Columbia River and its importance to national and regional economies. While we are not able to quantify those benefits and capture them, they are huge (as identified in the five bullets in the executive summary, e.g. 20 billion in international trade annually). The report does a good job of telling the story of the significance of maintaining the jetties from a technical standpoint but

some may not read past the apparently low BCRs to support funding requests of this magnitude. I could not find specific written documentation but believe I've heard a BCR below 2.5 is likely to be considered not worthwhile by OMB.

NWP Response (6/7/12): Noted. Detailed discussions will be occurring between NWD and NWP to present the best case possible for our FY 14 budget.

---

2. NWD Comment (5/31/12): The report recommends a significant amount of habitat improvement projects as conservation measures under Section 7(a) (1). It is not clear how these actions would be funded if they are implemented. These types of actions should be conducted under the authority of Section 1135, 536 or other ecosystem restoration authorities. The navigation budget does not have funding for these actions and they should not be accomplished with MCR project funding.

NWP Response (6/7/12): NWP's reference to habitat improvement measures may have confused NWD. We are not trying to improve the habitat, we are trying to mitigate for impacts from the federal action. One exception to this is the establishment of the snowy plover habitat. The compensation for impacts to wetlands habitat is 2:1, and waters of the US impacts is 1.5:1.

NWD Response (6/8/2012): Tentatively resolved pending review of revised EA.

NWD Response (6/14/12): Comment resolved.

COST ESTIMATES & NED

XX1. NWD Comment (5/31/12): It is our understanding that the Cost Estimate has not completed appropriate review and currently is underway. This action is incomplete and the cost estimate could change.

NWP Response (6/7/12): Concur. We expect to have a certified cost estimate by 15 June. Early review of the effort indicates an increase to the total project cost of approximately 7%.

Comment resolved: PCX certified cost estimate in 13 June 2012.

---

2. NWD Comment (5/31/12): The District should confirm cost terminology is consistent with the 25 August 2011 Corps of Engineers Civil Works Cost Definitions and Applicability guidance.

NWP Response (6/7/12): The district will confirm that cost terminology is consistent with 25 August 2011 Corps of Engineers Civil Works Cost Definitions and Applicability.

Comment resolved: PCX certified cost estimate in 13 June 2012.

---

3. NWD Comment (5/31/12): Sect. 2.6, 3rd paragraph. Although planning level estimates are certainly appropriate here, that term requires further explanation as to how precise the cost estimates were in this study. Later when it comes to alternative comparison in section 4.2, the alternative selection seems to assume an extremely precise level of estimate (less than 1%).

NWP Response (6/7/12): These were generated using the best available data and the cost estimate is being ATR'ed and certified. All of the alternatives use the same cost assumptions.

The terminology planning level estimates is being used in this paragraph to represent existing data. It is not to do a complete design and independent government estimate.

NWD Response (6/14/2012): Comment resolved.

---

4. NWD Comment (5/31/12): Sect. 2.7 This paragraph seems too critical to the report to be hidden in an appendix. Suggest the summary table be beefed up in the main report to provide somewhat of a breakdown of benefits (annual savings in dredging, maintenance, safety, etc.).

NWP Response (6/7/12): Concur. We will insert Table C-17 into Section 2.7 of the main report.

NWD Response (6/14/2012): Comment resolved.

---

5. NWD Comment (5/31/12): Section 4 (page A2-4-1) There is not an adequate description of the type, magnitude, and timing of the costs assumed for all alternatives. Without more details I cannot determine whether the economic costs/benefits are reasonable. Please provide some example simulations that describe and show the type of costs (ie dredging, repairs, rehab, spurs, head capping), the magnitude of these costs over time. The basis of this concern is ER1105-2-100 paragraph E-3.

NWP Response (6/7/12): Concur. The outputs will be added to the report.

NWD Response (6/14/12): Comment resolved.

---

6. NWD Comment (5/31/12): Section 3.5.4 Structural and functional reliability should be represented in the economics evaluation not as separate engineering criteria. This direction was included in the 30 June 2010 NWD Issue Resolution Conference guidance - comment 1c.

NWP Response (6/7/12): See NWP response under BLUF #3.

NWD Response (6/14/2012): Comment resolved.

---

7. NWD Comment (5/31/12): Section 4.5, third paragraph states that the NED plan and plans that do not limit the recession of the jetty head are "not statistically different". This Section seems to be arguing that the NED cost differences between some plans are not significant. This is a significant concern because it has the potential to result in a different NED plan. Please define what you mean by "not statistically different".

NWP Response (6/7/12): "Not statistically different" has been deleted. Added text to Section 4.5, South Jetty that reads: Although the base condition is the NED plan, the interim repair, hold head alternative is very close in AAC, differing by $85,000 or 0.9 percent.

NWD Response (6/14/2012): Comment resolved.

---

8. NWD Comment (5/31/12): The breakdown of the costs did not include required mitigation action or habitat improvement features. These are important to the overall project costs and required to be included in total project costs and alternatives consideration to determine BCR. Additionally, a CEICA of the habitat features was not included.

NWP Response (6/7/12): They are included in the cost analysis in the selected plan and are applied consistently across all alternatives.

NWD Response (6/14/12): Comment resolved.

HABITAT IMPROVEMENTS

1. NWD Comment (5/31/12): The project concluded that MCR work would result in no significant impact and thus, prepared the environmental assessment. Additionally, the ESA consultation process concluded with NMFS determination of Not Likely to Adversely Affect salmon and steelhead species, and specifically stated, "For Pacific salmon and steelhead, green sturgeon, and eulachon, NMFS expects construction-related effects on water quality, hydraulic and hydrological processes and estuarine, marine, and upland habitats to be insignificant or discountable." There is a discretionary conservation measure to carry out management actions as identified in the Columbia River Estuary ESA Recovery Plan Module. Additionally, there are some recommended conservation measures for snowy plover in the USFWS consultation letter. However, the described habitat measures (chapter 5) potentially commit the project to what could be viewed as excessive measures such as levees breaching, land preservation, and large scaled restoration actions. It also proposes to establish an interagency adaptive management team, and acknowledges a need for future NEPA and ESA documentation in addition to the project development of the habitat action (s). Our concern is the scope of actions presented are 1) not required, 2) are disproportionate to the scope of short and long term impacts, and 3) are, in many cases, based on provided Table 5-5 of the Evaluation Report, not within the MCR navigation project authority, would require additional authority to complete, and as stated, would require quite a bit of additional work. The Section 7(a)(1) proposals additionally have a potential fiscal law violation if the expenditures are not attributed to the proper authority. Additionally, 4) the work is 100% federal, dedicating obligations to the future O&M of the habitat projects. Our

recommendation is to pull all reference of additional habitat features from the document prior to public release, especially the FONSI, 404(b)1 analysis, and all information used for permitting purposes. The revised FONSI could include a statement such as "Habitat features were proposed in earlier documents as additional work the Corps could perform; however, they are not required or proposed as part of the MCR jetties MRR. They could be considered in the future under the appropriate authorities".

It is important to distinguish that regarding the habitat improvement measures, NMFS states: "These habitat improvement projects will require additional consultations, and the proposed AMT likely will be of assistance in this process. Furthermore, NMFS did not consider the beneficial effects of the habitat improvement projects in making our jeopardy/adverse modification determinations." This clarifies that NMFS is not viewing these measures as offsets to any anticipated impacts, nor have they adopted them into any RPAs.

NWP Response (6/7/12): Your assessment highlights an omission in the NWP documents NWP gave you to review, and we apologize for not clarifying. Except for the establishment of the snowy plover, the habitat improvement methods (HIM) are also compensatory impacts to aquatic resources that require mitigation under the CWA and as clarified under 33 CFR 332. NWP proposes to compensate for the aquatic impacts at a 1.5:1 ratio and compensate to the wetlands impacted at a 2:1 ratio. The wetland mitigation is identified in the 2012 EA and FONSI. The Section 7(a) (1) HIM complements the mitigation to compensate for impacts to waters of the US (aquatic resources). Since the contractor may or may not use the sites NWP has identified and analyzed in the 2012 EA and FONSI, an AMT will help the NWP identify what actual in-water impacts really need compensation. The AMT will be composed of federal and state agencies that have authority in regards to the mitigation. The 2012 EA and FONSI will be revised to make this clarification. This AMT process will allow NWP to compensate accordingly.

The report and the EA will be clarified to not include habitat improvement language. The Corps will rename the 7a1 actions to reflect that they are compensatory mitigation for impacts to aquatic resources.

The Corps coordinated with the States, USFWS, and NMFS to determine appropriate mitigation ratios based on functions and typical compliance requirements. Proposed wetland mitigation is at a 2:1 ratio and mitigation for waters other than wetlands is at a 1.5:1 ratio. Though WQCs have not yet been obtained, the Corps has been working closely with the Certifying agencies to ~~ensure~~ ensure meeting our legal responsibilities. compliance with anticipated clearance documents. The BA was based on and the BiOp evaluated a larger suite of actions so that a larger acreage of mitigation was proposed for impacts to aquatic resources. It is anticipated that through meetings and discussions with the AMT the total for proposed mitigation will decrease to reflect the reduced project footprint.

NWP will need to continue to work with NWD and FWS on the snowy plover issue. This is truly a Section 7(a)(1) mitigation as U.S. Fish and Wildlife Service (FWS) adopted the biological opinion (BiOp) that NMFS issued. A larger suite of actions was assessed in order to allow maximum flexibility in the execution of the contract, and still meet the intent of reducing environmental impacts.

NWD Response (6/14/12): Comment resolved.

---

2. NWD Comment (5/31/12): The report reiterates in section 5.4 that habitat improvement measures are not mitigation or to compensate for any project related impacts. While the report states further analysis would be required and discussions will take place in the AMT, it establishes expectations that the MCR project will evaluate the Table 5-5 projects and take an action. Additionally, the AMT is not described in the report, and conclusions as to the team purpose and composition is drawn from the NMFS Biological Opinion. It is unclear how this team has the responsibility and authority to be established, make decisions for Corps projects, or how its' activities would be funded.

NWP Response (6/7/12): Description of the AMT's purpose is described on pp 88 of the EA and will be added to the Report. The team will be comprised of regular government agency resource agency participants that have regulatory authority over various components of the project, including compliance monitoring. Annual or more frequent meetings as required would establish a regular venue for the Corps to present monitoring results; to ensure regular coordination with resource agencies under dynamic project conditions and changing species status; and to vet yet to be determined details on proposed mitigation actions. The Corps would retain decision-making authority. The list of potential mitigation actions was presented as examples of possibilities that could be considered for mitigation rather than commitments to specific project.

This descriptive language was included as such in the original final EA and on pp 88 of the revised EA. This passage states, "Due to the dynamic conditions at MCR and the long duration of the MCR Jetty Rehabilitation schedule, the Corps proposes formation of a modified Adaptive Management Team (AMT). The Corps suggests annual meetings to discuss relevant design and construction challenges and modifications, technical data, new species listings or critical habitat designations, evolving environmental conditions, and adaptive management practices as needed. The primary purpose of the proposed AMT and its implementation is to ensure construction, operation, and maintenance actions have no greater impacts than those described in the Biological Assessments and Environmental Assessment, and that Corps obligations and terms and conditions are being met. This will also allow confirmation that any necessary construction or design refinements remain within the range and scope of effects described during Consultations are being met and efforts are being made to adjust mitigation once final impacts are fully understood. These adjustments could result in a reduction in mitigation based on actual impacts occurring. This forum will provide an opportunity for periodic evaluation as to whether or not the proposed actions, ESA listings, or environmental conditions result in any re-initiation triggers. It will also facilitate continued coordination and updating and allow the Corps to inform agency partners when unforeseen changes arise. Results regarding marine mammal and fish monitoring, wetland mitigation and habitat improvement monitoring, as well as water quality monitoring will also be made available to the AMT in order to fulfill reporting requirements and to address any unexpected field observations. Results of jetty monitoring surveys will also inform the AMT of the repair schedule and design refinements that may become necessary as the system evolves over time. This venue will provide greater transparency and allow opportunities for additional agency input. Final selection and design of the habitat improvement and wetland mitigation proposal will be vetted through this forum to facilitate obtaining final environmental clearance documents for this component of the MCR proposed action. Potential principal partners include federal (National Marine Fisheries Service, U.S. Fish and Wildlife Service) and State (Washington and Oregon) resource management agencies." Further agency consultation will be required when mitigation details for waters other than wetlands are proposed. NEPA, ESA, and CWA compliance documents may need to be supplemented.

An AMT approach has been successfully utilized on the Columbia River Channel Improvements Project (CRCIP). This proposed AMT would be expected to perform a similar function.

NWD Response (6/14/12): Comment resolved.

---

3. NWD Comment (5/31/12): Note: The efforts of this future work have not been provided a cost estimate or included in the project evaluation and BCR. This is not an issue if habitat features and the AMT are pulled from the report. If a specific project(s) is pursued, it would have to be included in the cost estimate and evaluated with CEICA, and included in the BCR for the project.

NWP Response (6/7/12): Cost estimates were developed for compensatory mitigation based on a combination of costs of per acre of previous mitigation work at Lois Island, potential mitigation costs to purchase wetland bank credits, and based on estimates to complete various components of the mitigation actions. These were estimated for the MMR and MRR project as a whole and were included as such in both reports.

Because the mitigation sites have not been identified yet, a representative site (Lois Island) was used for costing purposes. It should be noted that this is intended to be a maximum cost and therefore, cost effectiveness and incremental cost analysis was not performed. The cost estimate is being certified by the NWW cost center of expertise. The district proposes to compensate for the aquatic impacts ranging from 1.5:1 to 2:1 ratio.

NWD Response (6/14/12): Comment resolved.

MITIGATION

1. NWD Comment (5/31/12): Chapter 5 of the report and NEPA document did a good job covering the environmental resources and potential impacts of the project. The design also appears successful in avoiding and minimizing any impacts to wetland resources in the project area. There still remains some unavoidable impacts to wetlands regulated under the Clean Water Act that require mitigation. In regards to the assessment of impacts in the North Jetty, a low quality lagoon of 8.02 acres would be filled. It is unclear if this lagoon is the same area evaluated and permitted as a MCR disposal site in 1999. A map would be helpful, however, I am looking for District confirmation we are not mitigating for something previously permitted.

Additionally, it should be clarified under what authority the mitigation is required, specifically, if this is classified as a wetland, or other waters of the U.S., as meeting the definitions in the CWA.

NWP Response (6/7/12): The district is confirming that the mitigation areas were not previously impacts, nor mitigation through a prior Corps action. Compensatory mitigation for impacts to aquatic resources is required under the Clean Water Act. A complete delineation is available for your review if required.

NWD Response (6/14/12): Comment resolved.

---

2. NWD Comment (5/31/12): Section 5.4, the proposed mitigation plan does not include an incremental cost / cost effectiveness analysis. The basis of my concern is ER 1105-2-100 paragraph 7-35h.. Cost of mitigation measures are part of total project costs and are included in the benefit-cost analysis of alternative plans. ER 1105-2-100 2-3 c (6) & 2-4 k (NED analysis). Additionally, mitigation measures require Incremental Cost Analysis. ER 1105-2-100 Appendix C, C-3 e. "An incremental cost analysis shall be performed for all recommended mitigation plans. The purpose of incremental cost analysis is to discover and display variation in costs, and to identify and describe the least cost plan. Mitigation analysis shall be presented in an analytical framework commensurate with other project benefits and costs so that rational decisions regarding mitigation can be made. The least cost mitigation plan that provides full mitigation of losses specified in mitigation planning objectives, and which is unconstrained except for required legal and technical constraints, shall always be identified and displayed." Note: Appendix E places mitigation costs at $6,548,886. Mitigation requirements are for CWA impacted wetlands comprised of 4.7 acres of wetlands and 11.52 acres of other waters of the U.S. The analysis is inconsistent with policy and ICA/CE should be completed.

NWP Response (6/7/12): Because the exact mitigation lands have not been identified yet, a representative site (Lois Island) was used for costing purposes. It should be noted that this is intended to be a maximum cost and therefore, cost effectiveness and incremental cost analysis was not performed. The cost estimate is being certified by the NWW cost center of expertise. The district proposes to compensate for the aquatic impacts ranging from 1.5:1 to 2:1 ratio.

NWD Response (6/14/12): Comment resolved.

---

3. NWD Comment (5/31/12): Per WRDA 2036, all mitigation requires a monitoring plan that includes monitoring until completion and adaptive management thresholds. This information was not supplied with the project documentation. The plan should be submitted and costs of mitigation and ongoing monitoring included in the project cost summary.

NWP Response (6/7/12): This will be drafted and included in the EA and Report. It will reflect intent to monitor prior, during, and 3 years after completion of project construction to meet all environmental compliance obligations and ensure successful establishment of compensatory mitigation actions. Monitoring was also discussed in the section describing the AMT function in the EA.

NWD Response (6/14/12): Comment resolved.

---

4. NWD Comment (5/31/12): Table 5-5. The first project needs to be differentiated from the mitigation project required for CWA compliance described in A2-5-17.

NWP Response (6/7/12): This will be clarified in both the EA and Report so that it is consistent with the descriptions of compensatory mitigation.

NWD Response (6/14/12): Comment resolved.

---

5. NWD Comment (5/31/12): Note. Table 5-5 is a comprehensive list of estuary projects. Some are familiar from earlier discussions on potential FCRPS BiOp compliance projects. This list should be evaluated for potential project to complete under the Section 536, 206, or 1135 for consideration of meeting estuary habitat restoration targets in the FCRPS BiOp.

NWP Response (6/7/12): These projects were also intentionally shared with the Estuary Program because though they had potential as MCR mitigation, the Corps would not be completing most of them for MCR actions.

The Corps will review the list to exclude federal levee removal or acquiring private properties. Any private lands and levee breaches will be removed from the report.

NWD Response (6/14/12): Comment resolved.

---

6. NWD Comment (5/31/12): The proposed mitigation seems excessive for maintenance of existing structures that have been in place for over 100 years. Most in-water impact will occur within the footprint of the existing structure and have only short term, minor impacts. There is not a clear description of the habitat value of the lagoon adjacent to the north jetty (or other wetlands for that matter) but it appears to be an area where sand washed and washes out during high waves and does not appear to be high value habitat or serve as rearing habitat for ocean or riverine species. The environmental write up discusses impacts of features such as groins that do not appear to be part of the recommended plan. Any mitigation should be commensurate with the value of those unavoidable impacts and only for areas beyond the limits of the existing project impacts/footprint.

NWP Response (6/7/12): See NWP response to Habitat Improvements comments 1 and 2. The report will be corrected to reflect the discussion in the EA. This is a continuation of the above comments and will be further clarified to reflect compensatory mitigation obligations under 33 CFR 332. Impacts include both a temporal and geographical scale and were described in the EA, and the functions and values assessments of the wetlands were included in the EA. Spur groins were evaluated in the EA but were not part of the preferred alternative. Ratios and amounts were justified in earlier comment responses. Cumulative impacts and effects to low-value wetlands and waters must still be considered. Wetland impacts were considered permanent ~~in nature~~

because they would be in place for over a year and mostly into perpetuity of the project. Ratios for wetlands were based on the delineations and functional assessments along with COE Regulatory practices, resource agency input, and WA and OR mitigation ratio guidance. Inwater habitat improvement/offsetting actions/waters other than wetlands ratios were set at 1.5 to 1. The Corps was revising the final EA when the report was submitted, and the original EA had the old proposed action in it, which included spur groins.

NWD Response (6/14/12): Comment resolved.

---

7. NWD Comment (5/31/12): This report and all future reports, BA's FONSIs, etc, should clearly distinguish mitigation verses environmental features. This report blends them, including in the FONSI, making it difficult to distinguish the project impacts and responsibilities, verses other things we would like to do. Additionally, mitigation has very specific reporting requirements, which must be clear upfront to DOI and typically, agencies who issued the mitigation.

NWP Response (6/7/12): As mentioned, the EA and FONSI are being revised to better clarify and describe compensatory mitigation actions. See NWP responses to Habitat Improvements comments 1 and 2.
A generic monitoring plan will be developed and included in both the EA and Report. Monitoring was also discussed in the section describing the AMT function in the EA. Bob has forwarded the mitigation database link into which the District must enter our mitigation actions. This information will also inform development of generic monitoring plan descriptions.

NWD Response (6/14/12): Comment resolved.

NEPA/ENVIRONMETNAL ASSESSMENT

1. NWD Comment (5/31/12): A comprehensive list of comments on the 2011 draft EA was included. The draft 2012 EA is listed as released, with no dates given. An indication of the comments on the revised project, and their resolution has not been provided. Additionally, the FONSI was not included in the review package. A review for legal and policy compliance could not be determined. Note, the FONSI is required to be circulated with the draft EA. The District has indicated that they have not completed the FONSI. As indicated by the District, the report has not been circulated consistent with policy to implement NEPA.

NWP Response (6/7/12): The EA and FONSI are both under revision pending resolution of Division and District comments, and a draft FONSI was provided to Division. The original Final EA had a response to comments from 2006 and 2011 PN periods and has been posted on the Corps' public website for over a year (See EA Section 7 beginning on approximately p 204 of the Revised EA). The MMR FONSI has also been posted publically for over a year, though it did not cover the full suite of MRR actions. Per 33 CFR 230.11 the draft FONSI for an O&M action does not need to be circulated for comment, but a Public Notice will be issued regarding availability of both the EA and FONSI. This project has also been reviewed under an

Independent External Peer Review process, the results of which have been posted on the Corps' public website.

Division verbally indicated (mtg 5/31/12) that District does not need to re-circulate the FONSI given the multiple opportunities for public comment.

NWD Response (6/14/12): Comment resolved.

---

2. NWD Comment (5/31/12): Page 5-1 & 5-2 discuss offsite mitigation opportunities. This is in conflict with mitigation identified earlier in the report. If onsite or adjacent mitigation areas are available, please provide justification for offsite mitigation sites.

NWP Response (6/7/12): The MRR will be revised to be consistent with the environmental documentation and commitments. Compensatory mitigation requirements for both MMR and MRR actions and potential mitigation sites are described in EA Section 5.6. Onsite or adjacent mitigation to address impacts is preferred, and a suite of possible mitigation measures were also included since adequate details regarding site potential were unavailable. Specific project selection and design will also be vetted through the AMT to ensure compliance and appropriateness. Details describing wetland mitigation indicated there are adjacent and onsite opportunities (see Section 5.6 pp 145-154). The list will be modified to not include private property.

NWD Response (6/14/12): Comment resolved.

---

3. NWD Comment (5/31/12): Page 5-2 recommends additional research studies, projects, and partnerships. Please clarify how these fit the scope and authority of the MCR jetties project.

NWP Response (6/7/12): These are collaborative efforts not specifically attached to the O&M responsibility of MCR. For instance, ongoing RM&E efforts funded through the Columbia River Fish Mitigation program will be shared with the adaptive management team and resource agencies to further their understanding of the species and their habitat use in the estuaries. It is not the intent that this project fund research actions.

4. NWD Comment (5/31/12): The EA was very thorough and well written. However, we recommend for future documents to limit information to relevant resources and discussions of impacts of the proposed project. For instance, while good information, the wetland scoring sheets, proposed mitigation site detailed analysis, etc, are not information needed in the report, but can be relegated to the project files and available for review should someone wish to see them.

NWP Response (6/7/12): Noted.

NWD Response (6/14/12): Comment resolved.

---

5. NWD Comment (5/31/12): The EA is currently being revised based on the revised proposed action, but there does not appear to be a public review period. The last time the EA was revised (in 2010) there was a 30-day public review period (see page a2-5-27). NEPA does not require public comment in this instance, but the last time the project changed the public did have an opportunity to comment. This may be viewed as a change in practice and could be troubling.

NWP Response (6/7/12): District Management and Counsel discussed re-distribution for public comment and determined that this was unnecessary. The decision was based on the following reasoning: there have been multiple opportunities for comment (2 Public Notice Comment periods and 3 public meetings); the final EA and the MMR FONSI have been publically available for over 1 year; the project footprint and schedule duration under the newly revised preferred alternative is smaller than previously proposed; the FONSI will be stated as Provisional, and therefore may require additional revisions based on the CZMA and CWA compliance documents; and the FONSI and final EA will be posted publically on the website and a PN will be sent announcing availability per 33 CFR 230.11. The comments from the IEPR are available on our public website.

NWD Response (6/14/12): Comment resolved.

---

6. NWD Comment (5/31/12): The draft FONSI is not concise and difficult to determine what the MCR final action will be, what are the specific mitigation requirements verses habitat features, and what the final conclusion is on compliance. The FONSI is written in such a way that its intended purposes are lost in the details that are covered in the EA, and should not be re-written here. Suggest revising the FONSI to a clear and concise findings. See 33 CFR 230.11.

NWP Response (6/7/12): Noted.

NWD Response (6/14/12): Comment resolved.

DATA GAPS

1. NWD Comment (5/31/12): Please provide a signed copy of the review plan.

NWP Response (6/7/12): DDN-PCX approved review plan was sent to NWD on 5 June.

NWD Response (6/14/12): Comment resolved.

QUALITY CONTROL/EDITORIAL

1. NWD Comment (5/31/12): The document has not undergone adequate DQC. The basis of the concern is EC 1105-2-410. Contradicting assumptions, erroneous references, and missing

graphics leads to a lack of credibility. The document needs to have a thorough DQC. Specific comments below.

NWP Response (6/7/12): The district will thoroughly check the entire document again.

Closed DQC: Revisions and QA of printed document is complete.

---

2. NWD Comment (5/31/12): Many references to other sections of the documents are incorrect. For example Section 2.3 references a description of the base condition in Section 3.15. The report does not have a section 3.15. Section 3.5.1.1 references to graphs and table are incorrect. Section 3.5.1.3 references to graphs and tables are incorrect. Figures 3-22 labels for figures are incomplete. Figure 3-23 labels for figure are incomplete. Section 4.2 last sentence refers to the Base Condition as described in Section 3.10.2. The Base Condition is not described in Section 3.10.2.

NWP Response (6/7/12): All references will be verified.

NWD Response (6/14/12): Comment resolved.

---

3. NWD Comment (5/31/12): At least 3 figures in the Evaluation Report are completely black (1-16, Table 1-2, Table 1-3, on page 1-22, Table 3-2, page 3-31) . Figure 3-16 is missing photo. Additionally, page numbering switches throughout the document (3-2, to A2-4-6, etc).

NWP Response (6/7/12): The electronic versions did not print properly. The following tables have been corrected: 1-2, 1-3, 1-4, 3-2, 3-3, 3-4.

NWD Response (6/14/12): Comment resolved.

---

4. NWD Comment (5/31/12): Section 1.5.4.4. is titled "Summary of repairs and modifications to the MCR Jetties", but the text of the section does not include such a summary. For example I don't believe the total cost of historical repairs is summarized here or elsewhere in the project history section.

NWP Response (6/7/12): Title changed to “Damage and repair trends for MCR Jetties”.

NWD Response (6/14/12): Comment resolved.

---

5. NWD Comment (5/31/12): The title for Figure 1-4 should say shoaling (typo).

NWP Response (6/7/12): This has been updated.

NWD Response (6/8/2012): Comment resolved.

6. NWD Comment (5/31/12): Figure 1-16, the label on the bottom line does not look correct (MCR bathymetry and dm disposal sites).

NWP Response (6/7/12): Labels have been corrected.

NWD Response (6/8/2012): Comment resolved.

---

7. NWD Comment (5/31/12): Section 2.1, last sentence should state "Benefits and costs are converted to average annual equivalents" not average annual cost equivalents.

NWP Response (6/7/12): This has been updated.

NWD Response (6/14/12): Comment resolved.

---

8. NWD Comment (5/31/12): Section 3.10.1 paragraph 5, this sentence states that "The top economic performing alternatives are presented in figure 3-41 in terms of functional and structural reliability". Structural and functional reliability are not economic performance.

NWP Response (6/7/12): Sentence has been rewritten to say:

The functional and structural reliability scores of the top economic performing alternatives are presented in figure 3-41.

NWD Response (6/14/12): Comment resolved.

---

9. NWD Comment (5/31/12): P. 1-20, 1st paragraph. Here and elsewhere, it isn't clear how you could have equal proportion of stone placed on both sides of the jetty when they are placed at different slopes.

NWP Response (6/7/12): The stone was placed where it was needed. The following sentence has been deleted:

"An equal proportion of stone was placed on the north and south sides of the jetty."

NWD Response (6/14/12): Comment resolved.

---

10. NWD Comment (5/31/12): Editorial: top of page 1-45 says concrete cap was 500 feet long, pg. 3-19 says 300 feet. Also, based on figure 1-27 it appears to have settled around 17', but this isn't discussed.

NWP Response (6/7/12): The precise dimensions of the concrete terminus given that it is 70 years old ranges between 300 and 500 feet with numerous repairs across time. Historical records are not consistent. In the 1930s a 400' asphaltic cap was constructed to seal the jetty head at stations 340-344 at elevation 23-26'. In 1941-42, the south jetty head was further repaired with 76,000 tons of stone and 14,000 cubic yards of concrete.

The concrete terminal is not intact and is indeed disintegrating and settling.

NWD Response (6/14/12): Comment resolved.

---

11. NWD Comment (5/31/12): Sect. 3.2.4. This reference needs to be update to the EC. Date is 1 October 2011.

NWP Response (6/7/12): This has been updated.

NWD Response (6/14/12): Comment resolved.

---

12. NWD Comment (5/31/12): Sect. 3.3.2. The point seems to be of deficient maintenance has significantly contributed to the near failure of the jetties "…more maintenance stone would have been expected.." This could also be read to mean that not as much maintenance was needed as expected. Suggest rewording to clarify the point.

NWP Response (6/7/12): The intent of this section is to describe the predicted maintenance levels to maintain the jetty structure at or near a constructed cross-section. The first method using .7x the construction volume per year of structure life is a rough estimate that could be used to predict required maintenance in the future. The second method, surveying the structure and measuring the volume of stone missing is a method of calculating how much stone would be required and using it to check the assumptions made by the first method. The SRB model represents a third method of predicting required maintenance to maintain the jetty structure. It is unclear to the comment evaluator how this section is attempting to make a point that "deficient maintenance has significantly contributed to the near failure of the jetties."

Sentence will be changed to: "In extreme exposure of the structure, the expected maintenance requirements described above would predict more stone would be required to maintain the cross-section integrity." EDIT MADE.

NWD Response (6/14/12): Comment resolved.

---

13. NWD Comment (5/31/12): Figure 3-21. A plan view would be extremely informative for the jetty head templates.

NWP Response (6/7/12): A graphical depiction would be helpful to illustrate those alternatives that included jetty head construction; however the jetty heads are not in the selected plans. Complete drawings will be generated when and if head stabilization occurs.

NWD Response (6/14/12): Comment resolved.

---

14. NWD Comment (5/31/12): 3.5.3.2. last paragraph. This explanation is extremely confusing. Suggest rewording.

NWP Response (6/7/12): This will be rewritten to read: Figures 1-24, 1-26, and 1-31 illustrate the original length modeled by USGS and the lengths and head positions of the authorized project. The loss of littoral sediment can be reduced by stabilizing the jetty heads which maintains the overall morphology of the inlet. Because the recommended jetty lengths for the considered alternatives are about the same as existing jetty head locations, it is not expected that the proposed project will have a negative impact on the hydrodynamics or sedimentation processes of the MCR inlet. EDIT MADE.

NWD Response (6/14/12): Comment resolved.

---

15. NWD Comment (5/31/12): Figures 3-22 and 3-23. Labels for templates aren't clear or are missing.

NWP Response (6/7/12): These have been corrected.

NWD Response (6/14/12): Comment resolved.

---

16. NWD Comment (5/31/12): Figures 3-34 through 3-36. Why is major jetty breach, emergency repairs not showing on graph?

NWP Response (6/7/12): The Major Jetty Breach Emergency Repairs are shown on the graph. They are located at "0" on the x-axis. This is because they do not occur under the new base condition where actions are taken to prevent a jetty breach, review of the base condition figures showing repair frequency indicates the Monte-Carlo likelihood of a breach in any given year is less than one (max of 0.5).

NWD Response (6/14/12): Comment resolved.

COMPLETION OF AGENCY TECHNICAL REVIEW

The Agency Technical Review (ATR) has been completed for the Major Rehabilitation Report of the Mouth of the Columbia River (MCR) Jetty System. The ATR was conducted as defined in the project's Review Plan to comply with the requirements of EC 1165-2-209. During the ATR, compliance with established policy principles and procedures, utilizing justified and valid assumptions, was verified. This included review of: assumptions, methods, procedures, and material used in analyses, alternatives evaluated, the appropriateness of data used and level obtained, and reasonableness of the results, including whether the product meets the customer's needs consistent with law and existing US Army Corps of Engineers policy. The ATR also assessed the District Quality Control (DQC) documentation and made the determination that the DQC activities employed appear to be appropriate and effective. All comments resulting from the ATR have been resolved and the comments have been closed in DrChecks[sm]

CERTIFICATION OF AGENCY TECHNICAL REVIEW

Significant concerns and the explanation of the resolution are as follows: the Stochastic Risk Based model and its documentation. The model code was modularized and further documented, revised as a single code for all three jetties, and the User's Guide completely rewritten. This was all reviewed again by the ATR team leader. All concerns resulting from the ATR of the project have been fully resolved.

Para. 2(a) Recommend clarifying that the revised base condition: interim repair, with jetty head recession applies to all three jetties. Also, add to the base condition description that the spur groins are no longer included. Resolve with Para. 4 table which implies that the North Jetty and Jetty A NED plans include capping by the term "hold head". Para. 5 table indicates that only Jetty A will be reassessed during DDR with respect to hold head alternative. Should this apply to the North Jetty also, and the South Jetty?evaluated

Submitted By: alan jeffries (907-753-2740). Submitted On: 08-Jun-12

1-0 Evaluation **Concurred**

Section 3.8 of the main report has been edited to describe the FY 2011 base condition, the revised base condition and the events that resulted in the revision. Please refer to the revised report 12 June. Jetty A and North Jetty will be maintained so that head recession is prevented. In the hold head alternatives, although the large bull nose is not constructed, the jetty terminous are rebuilt and the required cross section to stabilize them (North and Jetty A) will be designed in DDR. South Jetty will be evaluated prior to 2019, when repairs are scheduled to reach the end of the jetty. It is not certain that the South Jetty terminous is in the most optimal location, as the model evaluation did not show a measurable benefit in arresting the recession. The discussion to evaluate the South Jetty head location is in the recomendations and description of selected plan. The increased monitoring identified in the report will assit the district in tracking the changes in foundation erosion, and morphology changes due to S. Jetty head recession and, if necessary be able to adaptively manage the design.

4661912	Hydraulics	Major Rehabilitation Report	n/a'	n/a	n/a

(Document Reference: Main Report)

Executive Summary: The NED plans described in the bullet items for each jetty state that "head stabilization" is included for the North Jetty and Jetty A. This appears to conflict with the base condition described elsewhere (Appendix A1 part 16.f.) in which head capping is not included. It isn't clear if the term "head stabilization" is the same as "head capping". Also, recommend that that the spur groins be identified as features which will not be included in the base condition if that is the intent. Part 4.5: Same as above.

Submitted By: alan jeffries (907-753-2740). Submitted On: 11-Jun-12

1-0 Evaluation **Concurred**

Base condition does not include the re-capitalization of constructing the engineering features. See Exec summary, chapter 4 and chapter 7 for revised descriptions of the plans. The selected plans for North Jetty and Jetty A are scheduled repair (without the engineering features of spurs and the head capping previously designed). However, the model indicated that an economical advantage could be attained by reconstructing the failing cross-sections at the jetty ends instead of allowing them to recede without re-construction. This indicated to the team that some form of stabilization will be beneficial for the North jetty and Jetty A, but the large bull nose would not pay for itself over the 50 year life. Description of the South Jetty plan (base condition) describes the adaptive management that will be used with the increased monitoring to inform future maintenance decisions.

4661936	Hydraulics	Major Rehabilitation Report	n/a'	n/a	n/a

(Document Reference: Main Report)

Part 4.5: The NED plan for the South Jetty calls for evaluating head stabilization during the DDR and P&S stage. It is stated that if a haul road on the crest of the jetty is placed to allow for other repairs, then the stabilization of the head could be evaluated. However, the June 2010 MRR draft report appeared to base the South Jetty head capping construction on the assumption that a jack-up barge would be used. This would then not necessarily require the placement of a haul road on the crest for access to the end of the jetty for head capping. If a jack-up bagre is still potentially a viable and cost effective means of construction for jetty head capping, recommend adding this in a sentence to the NED plan bullet for the South Jetty.

Submitted By: alan jeffries (907-753-2740). Submitted On: 11-Jun-12

1-0 Evaluation **Non-concurred**

Unlike the 2011 report, the 2012 report has a construction schedule that works from the Jetty roots seaward. The EA allows for barge delivery and the contractor is not precluded from using a jack-up barge, the selected plan will not discuss contractor's means and methods as it may limit competition.

4661982	Hydraulics	Major Rehabilitation Report	n/a'	n/a	n/a

(Document Reference: Main Report)

Parts 4.5 and 4.6: It is not clear why omitting the South Jetty head capping and allowing head recession was selected for the NED if the cost is not statistically/significantly different. Also, in Part 4.6 the proposed South Jetty head station that will be considered for potential capping is 313+00, however, 315+00 was the station per the June 2010 MRR report. At that time also the North Jetty was recommended for capping at Sta 105+00 instead of the revised Sta 101+00. Recommend adding rationale for the revised head capping station (possibly more apropriately in Appendix A1).

Submitted By: alan jeffries (907-753-2740). Submitted On: 11-Jun-12

Revised 11-Jun-12.

1-0 Evaluation **Concurred**

The revised report has a much improved plan selection description. For the S. Jetty, even though the costs are close, the NED plan was chosen by the PDT and the decision is supported by NWD. The following excerpt from 4.6: "While the South Jetty NED plan is the base condition--allowing head recession--it's not statistically different from the base condition alternative holding at STA 313." Report has been revised to clarify districts intentions. The correct language is in the revised plan in section 4.5 under the description of the selected plan for South Jetty. Section 4.6 will be revised to match. Basically instead of indicating that "not significantly different" it says that the AAC's are very close, varying by .9 % (thanks we missed that text in 4.6 when we revised in 4.5) 313 is the station that is used in all the "hold head" alternatives. This is not the base condition for comparing alternatives. The name is misleading, however all alternatives, including base condition hold head were compared against the base condition that allows the jetty to recede. In the hold head alternatives the model would repair stations out to 313, instead of ignoring the degradation of the outer reaches in the alternatives that did not include head capping or "hold head" by repair. While this option proved economically viable for the Jetty A and North Jetty, the consequences of recession for South Jetty do not outweigh the costs of repairing to that station. The selected plan construction schedule indicates repair of South Jetty stations 258-290 in 2020, prior to that time it is anticipated by the district that the affects of shallow water disposal (recently approved and implemented) as well as an increased understanding of the inlet morphology derived from enhanced monitoring (multi-beam/photogrametric or LIDAR) will allow the district to track the changes in the jetties and inlet in a 3d model. This additional information will be used to inform the decision discussed in the revised selected plan for S. Jetty. In short, the head capping cannot be justified at this time but the district is confident that additional information will make for an informed decision in the future. We put that in the report so we won't be precluded from taking actions that modify our plan should we begin to see consequences to the stability of the inlet.

4662326	Hydraulics	Major Rehabilitation Report	n/a'	n/a	n/a

(Document Reference: Appendix A2)

Part 4.b (pg 78): This section discusses four parameters that are not represented in the SRB model: Vertical Deflation of Morphology, Littoral Sediment Inflow, and Impacts to Inlet Stability, and Impacts to Navigation. Residual risks of underestimating costs and potential compromises to funtional performance of the MCR Inlet are discussed. These four are all important factors which will be impacted by the revised base condition for the project (with no head capping) and should probably be mentioned in the main report. Recommend adding this same discussion to the Main Report (possibly to Part 3.6) and/or a brief discussion of residual risk to Part 4.3.

Submitted By: alan jeffries (907-753-2740). Submitted On: 11-Jun-12

1-0 Evaluation **Non-concurred**

Please refer to chapter 4 and 7 of the main report for discussion on head recession stabilization. The risk factors structural risk and functional risk are discussed and included in the final plan selection. A2 is considered a part of the report, other review comments previously recieved have indicated that thie information is appropriate in the appendix.

4674641	Economics	Other	n/a'	n/a	n/a

(Document Reference: Economic Appendix, Page 14 and Section 5a)

Assume that all base conditions have a minimum BCR of 1.0. Need to add caveat/note as it is not clear that this is the condition. Also, need to discuss that this is a "relative BCR" and if quantified that the BCR could be substantially greater than 1.0 as the minimum case.

Submitted By: Robert Patev (9783188394). Submitted On: 17-Jun-12

1-0 Evaluation **For Information Only**

The base condition is the scenario used to compare all other alternatives. Our guidance essentially assumes that the base condition has a 1:1 benefit-cost ratio. As for a discussion on the relative BCR, see Section 2.12.

Submitted By: Mark Brodesser (503-808-4914) Submitted On: 18-Jun-12

1-1 Backcheck Recommendation **Close Comment**

This fact should be clearly stated in Section 2.12.

Submitted By: Robert Patev (9783188394) Submitted On: 22-Jun-12

2-0 Evaluation **Check and Resolve**
Revisions in 2.12 2nd para: Revisions begin at "If None The MRR base condition (discussed in Sections 2.3 and 3.84) consists of a reasonably efficient plan in which thorough annual jetty inspections are used to initiate repairs when significant degradation is observed. Given the efficacy of the base condition, it is difficult for any alternative that includes large initial expenditures to reduce total present value costs. If none of the alternatives evaluated provide cost savings over the base condition, then the base conditions for all three jetties would become the least cost plan, this would result in an overall BCR of 1:1, indicating that the base condition was the most efficient plan for each jetty.

Submitted By: Robert Patev (9783188394) Submitted On: 22-Jun-12

2-0 Evaluation **Check and Resolve**

The following has been included in 2.12 For the North Jetty the incremental benefits are achieved by lowering overall repair costs through enacting a more pro-active maintenance plan which reduces expedited repairs by increasing scheduled repairs (see table 2.6 highlighted plan for North Jetty). A similar efficiency was found for Jetty A, and therefore both the North Jetty and Jetty A have positive BCRs reflecting the lower costs of the recommended plans when compared to the base condition. The South Jetty recommended plan is the base condition, therefore the individual BCR for the South Jetty is 1:1, (recommended plan divided by base plan). The South Jetty is also the most expensive of the three jetties to maintain, followed by the North Jetty (BCR (1.09). In order to calculate a combined BCR, the BCRs for each jetty are weighted by the cost of the recommended plan for that jetty. When the weighted average is calculated the least expensive Jetty, Jetty A (BCR 1.42) has less influence on the overall combined BCR than the North and South Jetties and a combined BCR of 1.1 results.

4674646	Hydraulics	Other	n/a'	n/a	n/a

(Document Reference: Main report, pg 52)

South Jetty has had significantly more repairs that either NJ or JA....however, the structure is being left off any advanced maintenance like NJ and JA. Please explain reason as it is not clear in report.

Submitted By: Robert Patev (9783188394). Submitted On: 17-Jun-12

1-0 Evaluation **For Information Only**

The last jetty rock maintenance on the Jetty system was on the South Jetty in 2006. NWP believed that the most critical repairs at this time are: 1) Dune augmentation to secure South Jetty Root. 2) Lagoon fill to protect North Jetty root/beachside trunk from being undermined. 3) North Jetty Trunk stations 86-99 These are captured as advance actions by either direct submission in the PBUD (dune augmentation) and a previously approved MMR.

Submitted By: Robert Patev (9783188394) Submitted On: 22-Jun-12

2-0 Evaluation **Concurred**

The terms used to describe the benefits in 2.5 have been editied, confusing terms have been changed and the following has been added for clarity. The specific navigation costs considered in this report are the costs of maintenance activities for the three jetty system, these costs can be summarized as the cost of repairing or rehabilitating the structure and the increase in dredging costs relative to the alternative being considered. The direct costs for maintaining the jetties are summarized in table 2.6 by alternative. The costs are differentiated by type of repair; a planned rehabilitation cost, a scheduled O&M cost and an expedited repair cost. Because the alternatives vary in the timing and scope of repair activity, the total costs for an alternative can be compared against the base condition to identify the most cost efficient maintenance strategy. If no efficiency in repair timing and scope can be found that is superior to the base condition, the base condition is identified as the most efficient means of maintaining the jetties, and therefore the most efficient means of maintaining navigation at the MCR. A more efficient means of maintaining the MCR jetties lowers the costs of maintaining navigation at MCR, therefore increasing the BCR even if the navigation benefits themselves do not increase.

4674663	Hydraulics	Other	n/a'	n/a	n/a

(Document Reference: Main report, Figures 3-40 and beyond)

It appears from these life-cylce diagrams that the structural and functional reliability end back up to the same values after 50 years and after we spend $300M for the repairs in 2015. Why is there no similiar investment planned in the system to increase reliability in 20-25 years and beyond?

Submitted By: Robert Patev (9783188394). Submitted On: 17-Jun-12

1-0 Evaluation **For Information Only**

The base condition and all alternatives were developed to maintain channel navigability. Functional reliability was a secondary calculation, to ensure alternatives are providing a minimum level of functional reliability for the MCR inlet. The selected plans all meet the minimum level. While the report supports interim repairs on the South Jetty, those plans are based on model repair volume estimates. The actual repairs to the South Jetty, and the others, will be tied to damage measured per the biennial bathymetric, photogrammetric and LIDAR surveys.

4676922	Economics	Major Rehabilitation Report	n/a'	n/a	n/a

Coordinating Discipline(s): Economics

During the previous review, the major concern had been the lack of defense of the Federal interest. This version is a vast improvement. You may still want to consider the following which may strengthen the case for "obvious Federal interest": * Using more recent vessel traffic or commodity values. The year 2009, as in the appendix, was a poor data point due to the economic downturn. * Page C-3, provide additional details on the present Columbia River deepening (cost, date of completion, etc). * Figure C-1 is great at showing the widespread reach and extension of the hinterland, but caution about showing the map w/ the containers. Many evidence suggests a shift in vessel deployments away from the West Coast once the Panama Canal is enlarged in 2014. * Provide a blurb on MARADs Marine Highway initiative and National Export Initiative, of which the Pacific Northwest is a key artery. * Besides stating that "only once has the jetty system been disrputed", emphasize the serious consequences of a breached jetty. Tremendous economic losses, thousands of vessels being rerouted, safety issues, long term emergency clean-up costs, etc. It may not need to be quantified, but discussed as a means of putting the Federal interest issue to rest. * Love the fact that you quantified the RED impacts--do you happen to know the increased tax revenues? (some I/O models can calculate those in addition to the jobs and income).

PDT will add information regarding MARAD in the exec summary "The Columbia River comprises the M-84 Corridor for the Marine Highway Program. It is noted by the US Department of Transportation as a truck bottleneck resulting in up to 750,000 truck delay hours and an area of major rail congestion. The marine highway serves to reduce the congestion."

Curiously, why was the Deep Draft PCX contacted to review the model? (The model appears to be more like a Coastal Storm Damage Reduction).

Brian answered my question about"fix as fail" repair vs. "scheduled repair" but other readers might also be surprised to see "fix as fail" unit costs lower than a scheduled repair. The term "fix as fail" implies an expedited or unplanned action.

Submitted By: Kevin Knight ((415) 977-8597). Submitted On: 18-Jun-12

1-0 Evaluation **Concurred**
Fix as fails unit costs are based on less durable, locally available, smaller jetty stone. Scheduled repair assumes we have the time to develop quarry stone that is more suitable for the site, larger, denser but not locally available and therefore more expensive.

Consider expanding the discussion on the "Without Project" Base Condition assumption and how the team derived this assumption (Brian explained the history to me over the phone).

Perhaps the biggest lingering concern is with the formulation (Brian said this is mainly because of the without project baseline assumption). Indeed, there are 71 alternatives and only a handful are actually cost effective. Even among the cost effective plans, there is enough margin of error to make them non-cost effective. Was there a possibility of reformulation? (modifying repair schedules, etc)? I'm aware that this study was delegated to the MSC, but understand that this type of analysis is precedent-setting as the Corps will be undertaking these much more frequently in the future.

Submitted By: Kevin Knight ((415) 977-8597). Submitted On: 18-Jun-12

1-0 Evaluation **For Information Only**
Cheaper alternatives all represent a level of maintenance that is "less than" the base condition and does not provide the minimum level of protection for the Navigation entrance. This is a result of the base condition being the minimally acceptable level of maintenance, therefore by definition, it's going to be the most efficient or nearly the most efficient means of maintaining navigation.

Attachment 9

(Appendix H)

Attachment C-1

COMPLETION OF AGENCY TECHNICAL REVIEW

The Agency Technical Review (ATR) has been completed for the Major Rehabilitation Report of the Mouth of the Columbia River (MCR) Jetty System. The ATR was conducted as defined in the project's Review Plan to comply with the requirements of EC 1165-2-209. During the ATR, compliance with established policy principles and procedures, utilizing justified and valid assumptions, was verified. This included review of: assumptions, methods, procedures, and material used in analyses, alternatives evaluated, the appropriateness of data used and level obtained, and reasonableness of the results, including whether the product meets the customer's needs consistent with law and existing US Army Corps of Engineers policy. The ATR also assessed the District Quality Control (DQC) documentation and made the determination that the DQC activities employed appear to be appropriate and effective. All comments resulting from the ATR have been resolved and the comments have been closed in DrChecks[sm]

Robert Patev
ATR Team Leader

CERTIFICATION OF AGENCY TECHNICAL REVIEW

Significant concerns and the explanation of the resolution are as follows: the Stochastic Risk Based model and its documentation. The model code was modularized and further documented, revised as a single code for all three jetties, and the User's Guide completely rewritten. This was all reviewed again by the ATR team leader. All concerns resulting from the ATR of the project have been fully resolved.
